This book is made up of three parts. The first deals with the microscope, and gives instruction for its use; the second considers the preparation and mounting of microscopic objects, and the third discusses the choice and use of microtomes. Every good workman should thoroughly know his tools, and, hence, he who aspires to be a good microscopist should make himself familiar with the construction of the microscope. Explicit directions are given for the testing and selection of the microscope, the objectives, and the accessory apparatus. In the second part Mr. Martin J. Cole describes, in successive chapters, each separate stage of procedure for the preparation of microscopic objects, and gives, in a convenient table for reference, a list of tissues and organs with the most suitable hardening, staining and mounting reagents. A feature of the present edition is the introduction of Part 3. Here Mr. G. West of the Botanical Laboratory, Edinburgh, has compressed into small space much practical information which, though most useful to the beginner, could not be readily obtained elsewhere.

Surgery: Its Theory and Practice. By William Johnson Walsham, F.R.C.S. (Eng.), M.B. and C.M. (Aberdeen), etc. Eighth Edition by Walter George Spencer, M.S., M.B. (London), F.R.C.S. (Eng.), Surgeon to Westminster Hospital. Philadelphia: P. Blakiston's Son & Co., 1903.

The eighth edition of this popular English surgery has been revised and elaborated by Mr. Spencer. A number of pages have been added and also many new illustrations. In its present shape it is an admirably concise and comprehensive textbook and fully up to date.

American Pocket Medical Dictionary. By W. A. Newman Dorland, M.D. Fourth Edition. Philadelphia and London: W. B. Saunders & Co., 1903.

The appearance of four editions of this work in about as many years tells, in no uncertain way, of the satisfaction derived from the use of a dictionary of small size and convenient arrangement. It is probably the experience of all that such books are consulted much more frequently than larger works. In this edition several thousand of the newest terms have been inserted, while the tabular matter of former issues has been retained.

Intracranial Tumors among the Insane. By J. W. Blackburn, M.D., Pathologist to the Government Hospital for the Insane, Washington, D. C. Washington: Government Printing Office, 1903.

This is the report of a study of twenty-nine intracranial tumors found among 1,642 autopsies among the insane. It is mainly of interest from the standpoint of the morbid anatomy and histology of the growths described, being of no clinical value, for all of the cases are without satisfactory antecedent history or observation. Almost the entire book consists of numerous plates and drawings which are well executed.

A Dictionary of Medical Science, containing a full explanation of the various subjects and terms of Anatomy, Physiology, Medical Chemistry, Pharmacy, Medicine, Surgery, Gynecology, Medical Jurisprudence, Dentistry, Veterinary Science, etc. By Robley Dunglison, M.D., L.L.D., late Professor of Institutes of Medicine and Medical Jurisprudence, Jefferson Medical College, Philadelphia. Twenty-third Edition. Thoroughly revised, with the Pronunciation, Accentuation, and Derivation of the terms, by Thomas L. Stedman, A.M., M.D. Philadelphia and New York: Lea Brothers & Co., 1903.

A work that has held its place in the front rank of authority for nearly three-quarters of a century needs no recommendation for continued usefulness. In being kept abreast of the times during twenty-two editions it has the almost unique distinction of successfully surviving the almost countless textbooks of that period. The author's purpose in making the dictionary a comprehensive "epitome of the existing condition of medicine" has been consistently kept in view by the present editor, whose endeavor has been not only "to give merely a bald definition or array of synonyms, but to explain the condition denoted by the term." Some of the old definitions have been made more concise, but the identity of the author has been preserved as far as possible in making such terms consistent with a rapidly advancing science. For the same reason the author's preferences have been respected in the choice of principal terms when the word preferred by him has not become absolete. The elaborate system of cross references will, however, quite effectually prevent any confusion of relative significance of synonyms. With the great increase of new medical terms the chief problem presented to the editor has been due economy of space. Many words now obsolete have been cut out and newer ones substituted. The table of doses has been omitted, but the doses expressed in Troy and metric values have been inserted with a description of the various drugs, and the official preparations have been made to conform with the directions of the U. S. and British Pharmacopœias.

The derivation of the words, when from the Latin or Greek language, is generally indicated, but in the case of the latter the Roman characters are substituted for the Greek. Throughout the work there are such abundant evidences of thorough, careful, and scholarly revision as to leave nothing to be desired in bringing it to its present recognized standard of completeness and excellence. It is our old friend coming again to us with renewed life.

# Society Reports.

## AMERICAN PUBLIC HEALTH ASSOCIATION.

*Proceedings of the Thirty-first Annual Meeting, Held at Washington, D. C., October 26, 27, 28, 29, and 30, 1903.*

THE association met in the Assembly Hall of the New Willard Hotel, under the presidency of Dr. Walter Wyman, Surgeon-General of Public Health and Marine Hospital Service, Washington, D. C.

**Opening Address.**—This was delivered by General GEO. M. STERNBERG. He spoke briefly of the association as an important factor in promoting the welfare of the people of the United States, not only from a sanitary point of view, but also in the way of national prosperity. He said the saving of valuable life contributed to the material resources of the country, and greatly increased the value of property in regions subject to invasion by epidemic diseases, or to fatal endemic maladies. He declared that the great prosperity of the Southern States during recent years depended largely upon the fact that they had been protected from invasion by yellow fever. He called attention to the epidemic of 1878, which caused a loss of $15,000,000 to New Orleans alone, and more than $100,000,000 to the entire section invaded. The method by which yellow fever was transmitted being now known, its prevention had become comparatively easy, and sanitarians had no longer any fear of the recurrence of extreme epidemics of the disease within the limits of the United States.

Although cholera and yellow fever and bubonic plague were no longer feared by sanitarians, we had not yet conquered our endemic filth disease, typhoid fever; and tuberculosis still claimed nearly 150,000 victims annually within the limits of the United States. Until these and other widely prevalent infectious diseases were practically stamped out, our self-imposed task would not be complete, and even then it would be necessary to enforce constantly the lessons gained by past experience to prevent a return to insanitary conditions and the penalties in the way of sickness and death which were inevitably associated with such conditions.

**Report of the Committee on Car Sanitation.**—This report was read by the chairman, Dr. GRANVILLE P. CONN of Concord, N. H. While the committee was not prepared to suggest reforms which would at once settle the much-vexed question, yet it was believed progress was being made, and the managers of railroads were coming more nearly in accord with public opinion, and that the problem was gradually being solved. In car sanitation there were many obstacles to be overcome which were not necessarily given much thought when considering the question of the hygiene of a dwelling. The house on wheels not only had the atmospheric influences which at all times surrounded the dwelling, but at different rates of speed this pressure was immensely greater than that upon the ordinary domicile, One should always consider the character of the occupants who, for the time being, were tenants, and had but little or no thought of the sanitation or well-being of those who might be the next passengers to occupy the same seats, and who, perhaps, had little or no appreciation of what an expert intsanitation would consider a healthy condition of personal cleanliness or of a habitation. All such matters must receive attention when the problem of car sanitation was considered, and the standard of excellency which the public might desire should always be kept in mind, and the conditions made as nearly the standard as possible. The more permanent the means and methods adopted by health authorities, the more satisfactory they will prove to the commercial world and the general manager. A vacillating policy on the part of health officers could not produce good results. The sensational and sentimental should be entirely excluded from quarantine and sanitation. The bare facts necessary for the protection of the lives and health of the people should prevail. The imaginary troubles of the fanatical observer, as well as of those who would try to solve the problem from a commercial point of view, because they had something to sell, should be relegated to oblivion.

**Transportation of Persons Sick with Transmissible Diseases.**—Dr. J. N. HURTY of Indianapolis, Ind., read a paper with this title. Among other things, the author stated that leprosy was not so easily transmitted as tuberculosis, and compared with the latter malady, in its destructiveness to human life, it amounted to nothing at all; yet the mere mention of the word leprosy caused a shudder, and a riot would result if an attempt was made to introduce a leper into a railway car. Influenza, also a transmissible and very destructive malady, killed a thousand where leprosy killed one, still people did not fear it sufficiently to take even ordinary precautions against it. All intelligent observers could clearly see the possible harm which might attend the transportation in railway trains of cases of smallpox, yellow fever, bubonic plague, diphtheria, scarlet fever, typhus fever, and leprosy, and in consequence, public opinion would not tolerate such a thing. An equal understanding in regard to pulmonary tuberculosis, influenza, and typhoid fever would develop a public opinion demanding that rational regulations intended to prevent transmission must be rigidly enforced. Special compartments for persons sick with communicable diseases were impracticable.

**Car Sanitation in the Republic of Mexico.**—Dr. JUAN BREÑA of Zacatecas said it was a well-known fact that the infectious germs of diseases were floating in the air and were by it deposited in the veneers, moldings, and ornaments of furniture, and thence again taken up by the air and inhaled with it, and for that reason writers on hygiene and sanitary authorities had again and again recommended simplicity of ornamentation, hardness of materials, and polished surfaces for the interior of cars. He referred to the construction of railway cars, the methods of cleaning them, the drinking water, water closet, and ventilation. The suggestions and observations made by scientific writers had been neglected, and very little or no attention paid to them up to date, and thus the grave defects were still existing. These obstacles, however, should not dishearten sanitarians, but they should incite them to preach and work with the tenacity of the water drop which falls upon a hard stone.

**Report of the Committee on Animal Diseases and Food**—Dr. D. E. SALMON of Washington, D. C., chairman, presented the report of this committee. He said the experiments and comparative studies of Theobald Smith had attracted special attention to the difference in virulence shown by tubercle bacilli from human and bovine sources when inoculated upon cattle. Smith also pointed out certain morphological and cultural differences in bacilli from these two sources, and in the location and histology of the lesions in cattle produced by such bacilli. He did not conclude, however, that bovine bacilli could not produce disease in the human subject, but said that bovine tuberculosis might be transmitted to children when the body was overpowered by large numbers of bacilli, as in udder tuberculosis, or when certain unfavorable conditions existed. He adduced evidence that four human cultures caused generalized tuberculosis in cattle; but Kossel suggested that it might be possible that the bacilli in cases of human tuberculosis under certain circumstances could likewise attain a very high pathogenic activity for cattle. Undoubtedly the German commission was confronting the two horns of a dilemma, either one of which was fatal to the views of Koch as stated with such positiveness at London. If the suggestion advanced by Kossel was accepted, one would conclude that Koch was wrong in his claim that human tuberculosis could not be transmitted to cattle, and thus with one blow the entire experimental support was destroyed which he had for his argument before the British Congress of Tuberculosis; and if, on the other hand, the conclusion was accepted, which followed from the principle laid

down by Koch for a discrimination between human and bovine bacilli, and which appeared to be favored by Kossel, one must admit that bovine tuberculosis was an extremely important factor in the etiology of human tuberculosis. Of thirty-nine cases of human tuberculosis tested, four, or over 10 per cent., were virulent for cattle, and would be classified as of bovine origin; but these four cases were all found among the sixteen cases of tuberculosis in children which the commission investigated, hence it was plain that 25 per cent. of the cases tested of tuberculosis in children would by Koch's method be classified as of bovine origin.

The author mentioned two lines of experiments that had been carried on under the Bureau of Animal Industry in order that one might serve as a check against the other, by de Schweinitz and Mohler. The experiments and observations indicated that the types of tubercle bacilli were very inconstant, and that under suitable conditions they readily changed in morphology and in virulence. A similar conclusion was reached by other investigators in working with the *avian* and *piscine* types of tubercle bacilli several years ago, and was reasonably to have been expected with the human and bovine types. Too much had been made of the slight differences in cultural characteristics in morphology and in virulence which had been observed in some cases, comparing the human and bovine bacilli.

While the committee agreed that it was advisable to scrutinize clinical evidence as carefully as possible before it was accepted as influencing the decision of such an important question, consistency demanded that one should accept clinical evidence bearing upon the transmission of bovine tuberculosis to man on the same terms that evidence was accepted as to the transmission of the disease from man to man. The rules which Koch formulated for testing the evidence of bovine infection were given by the essayist with such brief comments as the committee felt they deserved. The committee concluded that it would require much work to decide with even approximate accuracy the proportion of human tuberculosis caused by animal infection; but the fact that 25 per cent. of the cases in children investigated by the German commission, and 50 per cent. of similar cases investigated by de Schweinitz, showed by this test that they were caused by animal infection was sufficient to convince the committee that measures should be taken and enforced at once to guard against infection from this source.

**Report of the Committee on the Causes and Prevention of Infant Mortality.**—This report was read by Dr. Henry Mitchell of Asbury Park, N. J., chairman. Among the measures which were most promising for a further reduction of the mortality among infants, the committee directed attention to the following: (1) To secure a more general adoption of cleanly methods of the collection, cooling, and handling of cows' milk. It was not enough to destroy bacteria which had been permitted to gain entrance into the milk, for while pathogenic bacteria might be rendered innocuous, the toxins already formed were not affected by high temperature, hence no manipulation of the milk could be safely substituted for cleanliness in its collection and distribution. (2) To abolish breeding places for flies in dwellings and to exclude them from contact with food. (3) To encourage the erection of improved tenements in cities and to show the dwellers in crowded districts the advantage of residence in the suburbs. (4) To more effectually isolate all cases of the dangerous communicable diseases.

**Immigration and Public Health.**—Dr. A. J. McLaughlin of Washington, D. C., read a paper on this subject. In considering the danger to the public health from immigration, he said three factors must be taken into account: First, the physique of the immigrant; second, his destination; third, the presence or absence of communicable disease. The physique of the immigrant was by far the most important factor. Good physique was much more general among immigrants a quarter of a century ago than among the immigrants of to-day. With the change in the racial character of immigration, most marked in the past decade, a pronounced deterioration in the general physique of the immigrants, and a much higher percentage of loathsome and dangerous diseases, were noticeable. Destination was scarcely less important than physique, and it was the rule that aliens of a race having a low physical standard would invariably herd together in the overcrowded, insanitary tenement districts of our great cities; while the sturdy races of unskilled laborers were scattered over a wide territory and tended to establish little homes of their own in the country or in the suburbs of manufacturing towns or cities.

As to the question of communicable diseases among immigrants, the ordinary quarantinable diseases were eliminated by efficient quarantine methods, but certain communicable maladies, classed as loathsome or dangerous contagious diseases, existed among immigrants, and constant vigilance and considerable skill were necessary on the part of medical inspectors of immigrants to detect these cases and separate them from the healthy immigrants.

The most important of these diseases, because of its frequency, was trachoma. Of the total number of cases of loathsome or dangerous diseases found in immigrants, 87 per cent. were trachoma, and 10 per cent. favus. Permanent injury to sight was most likely to occur in cases in which early treatment was neglected. Among immigrants with trachoma, ignorance of personal hygiene and inability to secure proper treatment made the spread of this disease alarming and the consequence to sight disastrous.

The writer concluded that if the thousands of recruits for the sweat shop army which arrived each year could be checked for ten years, the present existing tenement house problem would solve itself. The terrible congestion of the tenements would be relieved, the scale of wages for the sweat shop worker would be elevated, and the general sanitary conditions of life in such districts as in the Lower East Side, New York City, would be improved sufficiently to reduce the menace to the public health from this cause to a minimum.

**Preparation of Vaccine Virus.**—Dr. John F. Anderson of Washington, D. C., said experimental work had shown that the germicidal action of glycerin was feeble. Recently some valuable work had been done with other substances than glycerin to be used in the destruction of the bacteria found in vaccine. These substances were sodium biborate, boracic acid, carbolic acid, chloroform, and potassium cyanide. Of these, chloroform seemed the most valuable. According to Green of England, by the use of chloroform vapor the crude pulp was freed from non-spore-bearing germs in from a few hours to seven days, while the active agent of the vaccine remained potent as long as in the glycerin controls, and in six cases longer. The quick elimination of the extraneous bacteria by this method was a great saving in time as compared with the use of glycerin, which rarely exerted its full effect before the fourth week. Chloroform being extremely volatile, could be allowed to evaporate from the vaccine under aseptic precautions after being allowed to act as long as desired. It would be especially useful in hot countries where the active agent in vaccine does not retain its potency long, or when, as in epidemics, sudden calls were made for large quantities of virus.

**Address of Welcome.**—This was delivered by Hon. H. B. F. Macfarland, President of the Board of Commissioners of the District of Columbia. After expressing his gratification that the association had assembled in Washington, he stated that the city had a particular

claim upon the interest of the association at present because of the work of improving the water supply and sewer systems which was in progress, and also because there was being made an earnest effort to secure legislation from Congress to enable the city to end the insanitary conditions in its alleys where the slums existed. It was fully realized that the health of the people was the first duty of the statesman, and that all else that could be done for this or any capital went for nothing if its health was not protected and promoted. He spoke of the importance of sanitary reform, and referred to the education of public opinion in Washington, whereby expectoration on the sidewalks and in public places had been stopped without the necessity of making a single arrest. He referred to the release of Cuba from the dominion of Spain, and her accompanying deliverance from the awful visitations of yellow fever, which were a plague to herself and a menace to the United States so great that Mr. Blaine once said that it would be wise to spend half a billion dollars if necessary for the purchase of the island, simply to stamp out that plague. Here and everywhere similar deliverance must be wrought by patient and self-sacrificing and public spirited endeavor.

**President's Address.**—Following Mr. Macfarland's welcome, SURGEON-GENERAL WYMAN, president of the association, delivered his annual address, during the course of which he gave an exhaustive review of the history of the association, its aims and objects, the researches into the fields of medical science which it had conducted, and the results it had accomplished. Coupled with this, he gave an epitome of the causes that led to the formation of the association, and the history of its growth by the addition, from time to time, of the various countries of the Western Hemisphere, the last of which to join the association and take up its part in the field of scientific research being Cuba, only recently liberated from the bonds that had prevented her from assuming her proper sphere in a study of one of the most deadly of plagues with which she had been for years afflicted. After reviewing the need and effect of sanitation, the sanitary laws of States and municipalities, Dr. Wyman paid a tribute to the unselfish medical men who, for the good of science and from a sense of civic pride, had repeatedly carried out investigations in the interest of the public health and given their services without thought of compensation to the public good.

**Report of the Committee on the Disposal of Refuse Materials.**—Mr. RUDOLPH HERING of New York City read this report. The committee pointed out that (1) different local conditions demanded different methods of collection and disposal; (2) that each municipality should select the method which, after a careful study of specific local conditions, and a further careful investigation of the cost of securing satisfactory results, proved to be the most economical in construction and maintenance; (3) that the problem must include the consideration of the methods and cost of handling all of the several kinds of refuse between the origin in the house and on the streets and the points of final disposal; (4) the several kinds of refuse being ashes, street sweepings and manure, dry rubbish, and kitchen garbage, swill or slop. The garbage question had now reached a point where the proper solution of each case required the aid of the engineering profession, just as the construction of sewerage and other sanitary works. The problem was to effect the sanitary collection and disposal of the above mentioned four classes of refuse at the least cost. In conclusion, the committee said that while there were several methods of satisfactory disposal, every one would not be the best for all cities. Each city should study the question as related to its own special condition, and from a large experience, both in Europe and ath ome, select what was found best for itself.

**Report of the Committee on the Etiology of Yellow Fever.**—Dr. JOHN W. ROSS, U. S. N., Washington, D. C., read his report. Reference was made to contributions to the subject of yellow fever since the last annual meeting. A table was presented of cases treated at Las Animas Hospital, Havana, from October 20, 1902, to October 20, 1903, showing the number of cases of yellow fever and of other diseases; also of the patients immune and non-immune to yellow fever. He said during the past summer there had been a sharp epidemic on the Mexican littoral. Havana was in constant communication with the infected ports; ten regular passenger steamers plied to and fro each month with a considerable passenger traffic, not to mention the number of other vessels. The quarantine was rigid in preventing the entrance of persons who had been exposed to infection until the period of incubation had passed, and also against the entrance of mosquitos from infected ports; but no precautions were taken against the entrance of baggage, bedding, or household goods from those ports. Such things came in without let or hindrance; yet not a single case of yellow fever originated in Havana. Seven cases of yellow fever occurring among men from these vessels were treated in the hospital in Havana during the last yellow-fever season, with no precautions except to prevent the access of mosquitos to the patients, still with no case of yellow fever contracted therefrom. Attention was called to the fact that this was but a repetition of the experience of the previous year. The chances of this also being an accident, considering the former history of Havana, seemed scarcely worthy of consideration.

The committee stated that there were minor problems in the etiology of yellow fever yet to be investigated. These were:

1. As to the determination of the period of the disease in man during which yellow fever could be transmitted to the mosquito, so far experiments had shown that it was transmitted somewhat over two days, *i.e.* in the first, second, and third days, but there were not sufficient experiments made to prove that the third day was the limit at which the mosquito could be infected. The importance of this determination was obvious.

2. The determination of the minimum period after feeding at which the mosquito could become infective. Reed had shown that this seemed to depend upon the temperature. A minimum period, in his experience, was twelve days in his first experimental case, and judging from observation of yellow fever as it occurred in nature, this was probably near the limit. Still sufficient proof had not been adduced that mosquitos contaminated in less than twelve days had not conveyed yellow fever. Since the determination of this point experimentally would involve producing yellow fever in probably a considerable number of human beings, and since the minimum in Reed's experiments agreed closely with previous observations by Carter on yellow fever, the committee did not think that additional experiments for this purpose were justifiable.

3. To determine if mosquitos other than the stegomyia conveyed yellow fever, and if other species of stegomyia besides Stegomyia fasciata could do so. The first was from analogy very improbable; the latter, for the same reason, was probable.

4 To determine if Stegomyia fasciata was found breeding at a distance from human habitations, *i.e.* if it was anywhere a true sylvan, campestral, or palustral mosquito.

5. A closer study of the hibernation of this insect was desirable, in order to determine (*a*) what proportion of the infected animal survived the ordinary winter in the Gulf States; (*b*) whether such as survived retained their power of transmitting yellow fever.

6. To determine if Stegomyia fasciata was capable of acclimatization in environments unfavorable to the immigrant mosquitos, also deserved observation and further experimentation.

7. To determine the distance across water that this insect was aerially conveyed. If desired, it would be easy to differentiate the blood-fed (not necessarily infected mosquitos) by observing if they deposited eggs.

8. Finally, it seemed advisable to determine directly by observation whether this mosquito was carried by railroad trains, and if so, in what number, and the general conditions of such transfer. On this might depend measures of land quarantine.

**Characteristics of the Stegomyia Fasciata Which Affect the Conveyance of Yellow Fever.**—Dr. H. R. Carter of Baltimore, Md., read a paper on this subject. Among the special characteristics of the stegomyia which affected its rôle as a carrier of yellow fever were: (1) Distribution. This was, generally, between latitudes 43N. and 43S. on the coasts and low plains of Africa, Asia, and the adjacent islands; Australia, and the Mediterranean basin of Europe. It was also general on the eastern coast of America from 38N. to 35 S. Lat. On the west coast it was found at Panama and Guayaquil, and its existence was implied from Guayaquil to Acapulco. In the United States it was general on the coast and low plains of the Southern States, except Maryland. (2) It was conveyed by vessels indefinite distances (from Cape Town to Savannah Quarantine); in much greater numbers and more often by sail than by steam vessels. (3) It lived a long time—154 days being recorded by Guitéras in the case of an infected insect. (4) Once having acquired the power of transmitting yellow fever, it retained it apparently as long as it lived—fifty-nine days being recorded. A consideration of these four postulates would render it advisable to safeguard the tropical countries of the East when communication is opened up between them and American ports infected with yellow fever, preferably by freeing the American ports of yellow fever. (5) It propagated preferably in artificial containers, but would also propagate in pools where such containers were not available. (6) In America it has been reported only in the vicinity of human dwellings, and seemed here not to be a sylvan, palludal, or campestral mosquito. From a consideration of 5 and 6 the war against this insect in America should be waged about the houses of men, and especially against water in artificial containers. The introduction of a water supply, piped to every house so as to do away with cisterns and water jars was the most important measure of sanitary engineering to free a town of this mosquito. Next to this was a system of drainage by covered drains to carry off the rain water and prevent pools. Cesspools were not objectionable on this score. The mosquito unquestionably hibernated in the United States either as adult larva or egg, but if the infected adult hibernated, either a very large proportion died, or else the infecting parasite must generally die in the hibernating mosquito. The first seemed more probable. (7) It was essentially a house mosquito, and was inclined to stay about the premises where it had fed. Hence the greater safety of the wholesale district of an infected city as compared with the residence portion. (8) It did not feed in the dark or in bright sunlight. Therefore, in bright daylight or at night without artificial light were the safest times to be in an infected place. (9) The cycle of the yellow-fever parasite in the mosquito before it could be conveyed to man was generally, in hot weather, about fourteen days or over. Prior to the accomplishments of this cycle (once called the "extrinsic incubation of yellow fever") the mosquito could convey this disease. (10) It was probably usually conveyed aerially less than 100 yards. In Havana the infected insect was believed to be never aerially conveyed 250 fathoms—1,500 feet—from the Havana shore. The direction of the prevailing wind during the day influenced its aerial conveyance.

**Report of the Committee on the Army Canteen.**—Dr. George M. Kober, chairman, Washington, D. C., read this report. Reference was made to the introduction of the canteen system, and after dwelling at great length on the increase of drunkenness, the increase of trials by summary or other courts for drunkenness and for offenses caused by drunkenness, increase of desertions, increase of absence without leave, effect of the abolition of the sale of beer at the posts on the morality and discipline of the command, the committee presented a series of recommendations looking to the reëstablishment of the post exchange and its conduct along the lines recommended by Munson in his "Theory and Practice of Military Hygiene," pages 820-822. The committee recommended the presentation to the Senate and House of Representatives in Congress the following resolutions adopted by the association:

*Resolved*, That this body deplores the action of Congress in curtailing the authorization of the army canteen or post exchange, and in the interests of general and military sanitation recommends its establishment on its former basis at the earliest possible date.

*Resolved*, That this body, in the interest of temperance and humanity, cordially invites the intelligent coöperation of a very large element of good citizens, who have been active in securing legislation against the sales in the military service of alcoholics of any character, in taking successive steps toward the betterment of existing conditions, and thus assist in controlling and largely curtailing an evil which it is powerless at present to prevent.

**Human and Bovine Tuberculosis.**—Dr. M. P. Ravenel of Philadelphia made some remarks on this subject. During the past year interest in the question of the relation between human and bovine tuberculosis had been unabated, and several papers of interest had been published bearing on the subject. In America, Theobald Smith and Gideon Wells had isolated cultures of the tubercle bacillus from human sources having the characteristics and virulence of the bovine organism. A number of new cases had been reported of accidental infection of man by bovine material, the most important of which was that of Troje, which appeared able to withstand the most severe criticism. A young butcher, in good health and with no hereditary taint, wounded his left forearm slightly while working on a tuberculous cow. The wound healed under treatment, but six weeks later showed signs of inflammation, and a tubercle formed on the internal face of the elbow. There were two small fistulæ on the forearm, and enlargement of the ulnar and axillary lymph glands. A month later the middle forearm was covered with granulations which steadily increased in area, and, in spite of treatment, at the end of two months assumed the character of lupus. Histological examination at this time proved the tuberculous character of the disease. Two years after the injury Troje found an abscess which extended into the deep muscular layers. The pus contained tubercle bacilli and the tissues showed typical tuberculous lesions. Some months after the glands of the left axilla and subclavicular space were extirpated and proved to be tuberculous. All possibility of infection from human sources was excluded by Troje. The speaker then reviewed the findings of the commission of the German Sanitary Bureau, in which it was admitted that in at least two out of thirty-nine cases infection with the bovine tubercle bacillus had caused fatal tuberculosis in man. The author felt that the genetic unity of the human and bovine races of tubercle bacilli, as well as their intertransmissibility, had been definitely demonstrated. It had also been proven that a certain proportion of persons, chiefly young children, met their death through infection with the bovine tubercle bacillus, but the knowledge at hand did not enable him at present to define the extent of this danger.

**The Effect of Lemon-juice in the Mixture Known as Lemonade upon Typhoid-polluted Water.**—Dr. Wm. G. Bissell of Buffalo presented a paper on this subject. The investigation, he said, was prompted by a newspaper statement purporting as coming from a board of health in one of the leading American cities, that lemon-juice in lemonade would render typhoid-polluted water safe for drinking purposes. Three different methods of testing were tried: (1) Infecting water with typhoid and adding lemon juice; (2) Infecting glass rods with typhoid and

placing them in lemonade; (3) infecting silk threads and placing them in lemonade. Culture tests with the first method were faulty. The conclusions drawn were: (1) That lemonade cannot be depended upon in this rôle; (2) That this method of sterilizing typhoid-polluted water should be discouraged.

**Studies of Media for the Quantitative Estimation of Bacteria in Water and Sewage.**—Mr. STEPHEN D. GAGE and Mr. GEORGE O. ADAMS of Boston offered a joint paper in which they stated that in a report at the Buffalo meeting figures were presented showing that by simplifying the usual culture media, higher counts of bacteria might be obtained, and that the counts on a new medium, Nahrstoff agar, were much higher than on the usual media. These studies had been continued, and while not completed, certain points were presented for consideration. In standard gelatin or agar, the beef broth was the most fertile source of variation, the amount of the nutrient matter in beef-infusion made by the usual method varying through wide limits. Studies of plain agar made with the various kinds of natural water showed that in the majority of cases the bacteria naturally present in the given water would develop in greatest numbers in a medium made with the same water. The salts naturally present in commercial agar had a detrimental effect, greater numbers of bacteria developing on media made with agar from which the natural salts had been washed out. Greater numbers of bacteria would develop on media made without glycerin than on the same media containing glycerin. With pure cultures of different kinds of bacteria on standard gelatin, agar or Nahrstoff agar the highest counts were obtained with the species studied on gelatin and the lowest on Nahrstoff agar. A reduction of the amount of Nahrstoff in Nahrstoff agar from 1.0 per cent. to 0.5 per cent. resulted in a considerable increase in the bacterial counts with various waters. When cooked in acid or alkaline solution the albumoses of Nahrstoff underwent certain changes in composition which rendered them better food material for bacteria than was the commercial product. Studies of the efficiency of water filters in removing bacteria when estimated by counts on different media showed that there was a considerable variation between the various media, the ratio between the numbers of bacteria in the raw water and in the effluent being affected by the period of incubation, the reaction and the composition of the media. With standard gelatin and Lawrence agar the ratio was less variable between different lots of gelatin. The writers recommend that a standard nomenclature be adopted for the various culture media, the names used to express, as far as possible, the composition of the media.

**On the Value of Tests for Bacteria of Specific Types as an Index of Pollution.**—Mr. H. W. CLARK and STEPHEN D. GAGE of Boston, in their joint paper with the above title, said that the principal types of bacteria used as indices of pollution were the colon type, sporogenes type, sewage streptococcus type, and occasionally the two so-called paracolon types, *i.e.* the aerogenes or enteritidis Gartner type and the chologenes type. The colon type was the most numerous of these in normal sewage, and was accordingly of the most value as a specific indication of pollution. Bacteria of the colon type could be detected in ordinary city sewage in dilutions of 1-10,000 to 1-100,000. The presumptive test as applied to the colon type, reacting as it did with some fifty-eight well-described species of bacteria, covered too broad a field unless followed by confirmatory tests. Tests for Bacillus coli at the Experimental Station at Lawrence had agreed well with results obtained by chemical analysis and by inspection of the sources of the samples. Surface waters having the greatest relative population on their watershed had shown bacteria of the colon type more frequently than others with less population. Ground waters, on the other hand, unless grossly polluted, never showed bacteria of colon type. Samples of shellfish from sources polluted and unpolluted had almost invariably shown the presence of Bacillus coli in the polluted samples and their entire absence in the non-polluted samples. Examinations for Bacillus coli in different volumes of water showed that tests in both one and 100 cubic centimeters should be made, the tests in larger volumes being confirmatory of the tests in the smaller volumes, and in cases in which a considerable number of samples were taken from the same source, tests in the larger volumes usually gave more information day by day as to the quality of the water than did the tests in one cubic centimeter. Epidemics of typhoid fever coincident with the findings of Bacillus coli in normally pure waters, *i.e.* in waters known to be safe under ordinary conditions, but becoming dangerous by the accidental entrance of polluted water, had occurred within the observations of the writers, in which, although the entrance of this pollution was known, the danger was not indicated by chemical tests or by an increase in the numbers of bacteria beyond the usual limits of variation for waters of this class. Comparative tests for the relative viability of Bacillus typhosus and Bacillus coli showed that there was a very great similarity between the length of life of the two germs under a great variety of conditions.

**Isolation of Bacillus Coli Communis from the Alimentary Tract of Fish, and the Significance Thereof.**—Mr. GEORGE A. JOHNSON of Poughkeepsie, N. Y., read a paper on this subject. He stated that it had been shown that the colon bacillus was taken up by fish, and the results of the experiment described indicated that it multiplied rapidly in the intestinal tract of the same. It had been shown that a search of a large number of fish caught in an unpolluted water failed to reveal the presence of this organism in the intestinal tract. It would seem possible, therefore, that fish, having taken up the colon bacillus from a polluted water might migrate to a water of comparative purity where they would naturally discharge the greatly increased number of these organisms. Whether the finding of the colon bacillus deposited in a water in this manner would depreciate the value of the colon test in the examination of a public water supply was a question. It would certainly appear that if the colon bacillus could be thus easily transferred from one water to another the transportation of the typhoid bacillus might be considered quite as likely. At least the above results might explain those cases in which Bacillus coli communis was found in comparatively large numbers in waters apparently open to but remote chances of fecal contamination.

**The Bacterial Examination of 104 Samples of Water, Together with a Detailed Study of the Colon Bacillus.**—Dr. WM. G. BISSELL of Buffalo, N. Y., read a paper on this subject. In connection therewith he said that after consulting with many laboratory workers it had been decided to inaugurate an investigation along the following lines:

*First Division.*—To ascertain what constituted a colon bacillus. A recapitulation of the results demonstrated that the amount of gas produced, the production of indol and putrefactive odors were not constant factors with even true coli; that many of the lactic acid organisms are a close resemblance to colon bacilli; and that it was not safe to depend upon presumptive tests alone in determining the presence of colon bacilli in the water.

*Second Division.*—The amount of water advisable to test in arriving at an indicator of pollution: One hundred and four samples of water coming from Niagara River were examined at respectively twelve and twenty-two miles below a point where the sewage of over 400,000 people was received. Different amounts of each sample were examined and the comparative frequency of the presence of colon bacilli determined. A summary of the results demonstrated that colon bacilli were present in 52 per cent. of the samples when 1 c.c. was the amount examined at the twelve-mile distance, and in but 34 per cent. when 1 c.c. was the amount examined at the twenty-two miles distance. Both sides of the river were used for farming purposes. Many samples were col-

lected during heavy rainfalls. A recapitulation tended to demonstrate: (*a*) That colon bacilli were not found in all c.c. amounts of the sample. (*b*) That there was a decrease in the number of colon bacilli, the greater the distance down the stream. (*c*) That the heavy rains did not seem to increase the number of colon bacilli, although the land was used for farming purposes.

*Third Division.*—A test was made as to the longevity of colon bacilli in natural water. Excrement from the horse, cow, and from human beings was placed respectively in each of three wells. A test was made of each well at different periods. The results tended to demonstrate that colon bacilli could live in well waters at least 109 days, and that the human variety seemed to have a greater resistance than that from other sources.

*Fourth Division.*—Tests were made to determine the degree of frequency with which colon bacilli could be found in water known to be polluted with sewage. The results obtained tended to demonstrate that not all cubic-centimeter amounts of such samples demonstrated the presence of the organisms. The writer believed that many organisms had been mistaken for the colon bacilli in water work.

*Fifth Division.*—Tests were made to ascertain the degree of frequency with which colon bacilli could be found in water not presumably polluted. This work was necessarily confined to well water. Results tended to demonstrate that there were many wells, the waters of which did not contain colon bacilli even though larger quantities were examined.

**A Simple Method for the Routine Detection of Colon Bacilli in Water.**—A paper on this subject was presented by Dr. ROYAL STOKES of Baltimore, Md. This paper proposed the use of neutral red in a fermentation tube containing 1 per cent. lactose or milk-sugar bouillon, for the routine detection of colon bacilli in drinking water. If the percentage and amount of gas, the acidity, and the typical yellow-red contrast reaction all occurred, the organism could be considered as Bacillus coli communis. This was a much shorter method than the isolation in pure culture, which took from five to seven days, and would also make it easier to carry out quantitative experiments. These four distinct characteristics would seem to be sufficient to identify the colon bacillus in simple routine work.

**Report of the Committee on the Significance of Bacillus Coli in Water Supplies.**—Mr. S. C. PRESCOTT, Chairman of this committee, said in substance that to present a statement of the opinion of the committee individually and as a whole as probably representing the generally accepted views of sanitary bacteriologists as to the significance of Bacillus coli in water, the following questions were sent to each member. The answers appended, except as otherwise stated, were practically as given below:

"1. In view of the fact that numerous investigators have found B. coli in nature when it could not be directly traced to sewage or fecal pollution, do you believe that the colon test of water is as safe an index of pollution as it was formerly regarded to be? *Yes.*

"2. Are you of the opinion that the number of colon bacilli rather than their presence should be used as a criterion of recent sewage pollution? *Yes.*

3. To pronounce a water sewage-polluted, would you require as evidence that B. coli was present in a majority of one cubic centimeter samples? *Yes, in general.*

4. Are you in favor of recommending that the examination of large samples for B. coli (100-1000 cc.) be discouraged? Four members say in reply, *Yes.* One says, *No.*

"5. In case of a strong presumptive test, what confirmation tests would you require to make certain that the organisms present were B. coli? *Full set of distinctive cultural tests.*

"6. In view of the probable presence of streptococci in polluted waters, do you think it desirable that they be isolated as well as B. coli to confirm suspicious evidence of pollution offered by B. coli? Two could not recommend this; one thought it would be advantageous occasionally, but not practicable because of increase in routine work; one believed it should be done, when possible, for the sake of securing additional data, and for its general confirmation of the colon test; and one was indefinite."

**A Critical Study of the Methods in Current Use for the Determination of Free and Albuminoid Ammonia in Sewage.**—Mr. EARLE B. PHELPS, in considering this question, said that the work which he presented was the first part of a study which would eventually cover the whole field of sewage analysis. It aimed to show what accuracy might be expected from the various processes now employed in sewage analysis, and what modifications, if any, would make them more applicable to the problems of sewage disposal.

*The Free Ammonia.*—All free and saline ammonia, the writer stated, was recovered quantitatively in the distillate. Many proteids and other nitrogenous substances gave off ammonia when distilled with sodium carbonate, introducing a serious error in the analysis. This error was greatly increased in the case of sewage, owing to the unstable nature of many of its compounds. A method for the direct reading of the ammonia was suggested. In the process of nesslerization, the error due to the temperature and other minor errors were discussed.

*The Albuminoid Ammonia.*—The ratio of the albuminoid nitrogen to the total nitrogen was determined for a number of pure substances, and for a large number of sewages. These ratios showed wide variations not only among the various substances, but among the sewages themselves.

Owing to these variations, which seemed to depend upon the nature of the substances in the sewage and not upon the amount of organic matter present, it was strongly recommended that the present method of determining the albuminoid ammonia be given in favor of a determination of the total organic nitrogen by the Kjelhahl process, a simple and rapid modification of which was proposed for use in sewage work.

**A Dangerous Food-preservative.**—Dr. CHARLES HARRINGTON of Boston, Mass., in a paper on this subject, stated that sodium sulphite was used very extensively as a food-preservative, and more particularly for its effect on the color of chopped meat (Hamburg steak) and certain canned vegetables (asparagus and corn). The assertion made in 1896 by Kionka that it was a dangerous admixture had been combated by a number of experimenters and reaffirmed by Kionka and Schulz. Dogs fed on meat containing 0.20 per cent. of the salt were found by them to present extensive lesions in almost every organ, while others fed in the same way by Lebbin and Kallmann showed nothing abnormal. In this experiment five cats were fed for five months on beef containing 0.20 per cent. and a sixth one with untreated beef. All six began at once to gain in weight, but at about the ninth week all but the control began to lose, and they continued to do so up to the twentieth week, when all were killed. The organs of the control were normal. The chief lesion observed in the others was a parenchymatous degeneration of the kidneys. Each of the five presented cloudy swelling and marked fatty degeneration of the renal epithelium. Acute interstitial nephritis was present in one case.

**The Termination of Quarantine in Diphtheria.**—Dr. T. W. SALMON read this paper, which had been written, he stated, because of the very great importance, in considering the duration of quarantine in diphtheria, of knowing just how long diphtheria bacilli persisted, in those who had had the disease, and of detecting what constituted satisfactory evidence of their final departure. One hundred consecutive cases of diphtheria, which occurred at the Willard State Hospital, had been studied with reference

to these features. The cases were analyzed in some detail in the paper, and an effort made to show: (1) In what proportion of the cases a single negative culture from the throat would have been satisfactory evidence of the disappearance of diphtheria bacilli. (2) In what proportion of the cases two negative cultures from the throat would have been sufficient. (3) In what proportion of the cases three negative cultures from the throat would have been sufficient. (4) In what proportion of the cases cultures from the throat alone would have failed to reveal the persistence of diphtheria bacilli elsewhere. The causes for failure to detect the bacilli when subsequent culture showed them to be present were briefly considered.

Election of Officers.—*President*, Dr. Carlos J. Finlay, Havana, Cuba; *First Vice-President*, Dr. J. R. Monjaras, Mexico City; *Second Vice-President*, Dr. W. C. Woodward, Washington, D. C.; *Secretary*, Dr. Charles O. Probst, Columbus, Ohio; *Treasurer*, Dr. Frank W. Wright, New Haven, Conn.

Havana, Cuba, was selected as the place for holding the next annual meeting.

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON SURGERY.

*Stated Meeting, Held October 12, 1903.*

ROBERT T. MORRIS, M.D., CHAIRMAN.

**Methods for Suturing the Prolapsed Kidney.**—Dr. A. H. GOELET presented a paper on this subject. He said that the patient should be carefully prepared so as to minimize the disturbance resulting from the anæsthetic, and particular care should be taken to detach completely the colon from the kidney so as to obviate subsequent dragging upon the kidney when the bowel became distended. Reattachment of the colon to the kidney should be prevented by packing gauze under and in front of the kidney and resorting to early evacuation of the bowel. The suture material must not be such as to stretch or absorb. The suture should not be tied in the muscles, nor must it be removed until firm attachment had been secured. The kidney should not be attached lower down than normal. The patient must be kept on her back during the period of confinement in bed, when both kidneys were involved, or turned only on the affected side when only one kidney had been operated upon. She should not be allowed to get up until the end of three weeks. The conditions dependent upon the prolapse must receive attention. In performing the operation the patient should be placed prone with the pillow under the abdomen, and a vertical incision made through the skin of the back down to the first layer of muscle, and the aponeurosis slit upward and downward to the extent of the external wound. The latissimus dorsi should be separated by blunt hooks. Keeping to the outside off the erector spinæ muscle, the fascia attached to its upper border was split or separated with blunt hooks, care being taken to avoid opening the sheath of this muscle. The quadratus lumborum muscle was retracted, and then the fascia transversalis was exposed. Upon carefully opening this fascia the fatty investment of the kidney came into view, and usually, also, a knuckle of intestine. The fatty capsule was detached from the kidney by the finger and blunt scissors, the lower pole being freed first. If the kidney could not be delivered through the incision by traction on the capsule the patient was rolled downward. The fatty capsule should be completely detached from the kidney around both poles and on each side back to the hilum. The sustaining sutures, two in number, were inserted on the posterior free aspect of the kidney. For suture material he preferred silkworm gut which had been boiled and then preserved in a three-per-cent. solution of lysol. Each suture was inserted three times under the fibrous capsule in such a way that the strain upon it was parallel with the surface of the kidney and its capsule, and not at a right angle, as with other methods of suturing the kidney. The sutures were brought out upon the external surface of the back, and were tied over a fold of gauze, placed lengthwise of the incision. The sustaining sutures were not removed until the twentieth day. The author stated that he had done this operation 171 times upon 134 patients without a fatality, and without any failure to fix the kidney.

Dr. H. LILIENTHAL said that he had made use of the Goelet method so far as related to the insertion of the sutures into the kidney, but had not tried the plan of tying them over gauze. The method was a good one, so far as it secured a firm hold upon the kidney and raised this organ. An important feature of the method was that as the sutures were tied the kidney was raised still higher, and for this purpose the Goelet suture was decidedly superior to that of Broedel. Despite these advantages it must be said that the kidney capsule was sometimes so very friable that it would tear, no matter what method of suturing was employed. He made use of forty-day chromic catgut. The gauze packing underneath the kidney was of the greatest importance in replacing the organ. In this connection he desired to say that he had devised a middle piece for his operating table whereby the patient could be raised into the kidney position. This, in his position, was vastly superior to the use of a cushion.

Dr. ARNOLD STURMDORF said that it had been pretty well proved that simple denudation of the kidney without removing the capsule would not secure permanent anchorage of the kidney. Most operators of experience in this field made use of some flap formation for fixation, but the raising up of the capsule interfered with the nutrition of the latter. It had been proven that it was not the low position of the kidney in the abdomen that caused the symptoms, but the mobility of this organ. He could not see that it was possible to avoid mutilating the parenchyma of the kidney by the method of inserting sutures advocated in the paper. The insertion of the sutures parallel to the longitudinal axis of the kidney was nevertheless a step in advance. Sometimes in stripping off an extensive fatty capsule the kidney was cut into inadvertently.

Dr. A. ERNEST GALLANT said it was practically impossible to fix the kidney in its normal position because the diaphragm was bound to make it move; hence, one must go above the twelfth rib. In reality, the *fixed* kidney would be a painful kidney because the motions of the diaphragm would drag upon this organ. If a kidney were mobile, but did not go down low enough for the corset or waistband to press upon it, it would not be painful. If the kidney were sutured in a position in which the corset or waistband could cause such pressure, there would be distress, even after the kidney had been fixed by operation. He suggested that before operating for fixation of the kidney the surgeon should ascertain what size of corset the patient wore, and should then tie a bandage around the waist snugly to the size of the corset. He should then, before removing this bandage, make a mark on the back which would serve as a guide during the operation. He felt sure that if the kidney were fixed within an inch of this level therewould be subsequent distress. A kidney situated below the waist line would not, ordinarily cause discomfort.

Dr. Lilienthal remarked that a more accurate idea of the size of the individual's waist could be obtained by asking the woman the size of her waist rather than the size of her corset, because of the various degrees of tight lacing practised.

Dr. GALLANT said that when one recalled the dense peritoneal adhesions met with it was easy to believe that adhesions could be produced artificially which would be abundantly strong to support the kidney without resorting to the splitting process. Dr. Ramon Guitéras made use of a flap method which brought the kidney very nearly into its normal position. He believed Dr. R. T. Morris

was the first in this country to insist that the shorter the time the patient was in bed the better, other things being equal, and, personally, he believed that Dr. Goelet went to an extreme when he insisted upon the patient's remaining in bed for three weeks.

**Avoidance of Vomiting after Etherization.**—Dr. Gallant said that his own method of avoiding severe vomiting was by giving minute doses of morphine twenty minutes before the etherization. For a person weighing 100 pounds, or less, he gave $\frac{1}{12}$ of a grain, for one weighing 125 pounds, or less, $\frac{1}{8}$ of a grain, and for one weighing over 125 pounds, $\frac{1}{6}$ of a grain. In a few cases in which vomiting occurred despite this precaution the patient should be encouraged to drink very freely of hot water, even if this were vomited, it acted beneficially by washing out the stomach and thus leading to a cessation of the vomiting.

Dr. Robert T. Morris said that if the peritoneal cavity were opened an element of great discomfort was introduced, *i.e.* an intense thirst, perhaps lasting for twenty-four hours. Dr. Goelet's good results with an intact fibrous capsule were certainly not in accord with the experience of the early operators. In the history of the development of the operation it was noticeable that there had been a growing tendency to denude the kidney of its capsule more and more extensively. Dr. Goelet's suture certainly gave a firm hold, yet he would expect the capsule to tear out at certain points. Moreover this method of suturing could not be employed if the capsule of the kidney were removed. He had personally given up the use of the flap for the reason that he could not secure quite so good approximation of the muscles afterward. The final result of these operations was one in which there was a widespread interest. It was his practice to keep these patients in bed for fourteen days, and so far this plan had not been followed by any bad consequences.

Dr. Goelet thought the chief objection to fastening the sustaining sutures of the kidney to the muscle or using a flap was that the kidney could not be elevated sufficiently to bring it above the waist line and beyond the reach of corset pressure. He believed that in many women the cause of the prolapse of the kidney was the dragging down of this organ by the colon. He had only found a thin fibrous capsule in those cases in which there was an effusion under the capsule, and between it and the substance of the kidney. He had met with several such cases. He would like to know if any of the surgeons present had made use of any forceps to facilitate the dragging out and delivery of the kidney through the wound. He did not carry the suture out above the upper angle of the incision, and hence, he did not think there was any likelihood of wounding the pleura, as had been suggested. He took out the gauze drain at the end of two days because when removed at this time there was always considerable discharge. For this reason he objected to leaving the gauze in longer. While it was true that the patient might not complain of pain if the kidney were fixed low down, it should not be forgotten that even these kidneys showed abundant evidence of nephritis. He could not accept the statement that the symptoms of prolapsed kidney were due solely to the mobility of the organ, for the prolapse gave rise to interference with the flow of urine through the ureter. While absolute fixation of the kidney was not what was desired, the mobility must be considerably restricted. The failure of the earlier operators might, perhaps, be attributed to the use of transverse sutures.

**A Device for Easily Everting the Eye-lids.**—Dr. Frederic Griffith exhibited a simple device for this purpose, originating with Dr. E. H. Snow, and intended for the rapid eversion of the eye-lids for purposes of examination. It was nothing more than a hairpin, the two free ends of which were inserted into a cork for a handle. The speaker said that he had seen the eye-lids of four hundred immigrants thoroughly everted and inspected in the course of an hour by the aid of this simple little instrument.

**Appendectomy, Cholecystotomy, and Cholecystectomy.**—Dr. Goelet presented a gall-bladder containing calculi. He had first operated upon the appendix, and had performed cholecystotomy, but at that time, February, 1901, found no calculi. Subsequently, attacks of colic jaundice necessitated removal of the gall-bladder, and at this operation, done a few months ago, a number of calculi had been found in the gall-bladder.

Dr. Lilienthal said he believed that a gall-bladder that was worth operating upon at all was worth removing. He had done over fifty primary cholecystectomies within the past three years, and had not lost a single patient, although some of them had been in very bad condition at the time of the operation. He had lost three patients in whom the cholecystectomy was secondary. He did not now ligate the cystic duct until he had opened it widely and tied the cystic artery. He would not take the risk of closing the abdomen after a cholecystectomy without drainage. It was seldom that the incision for this operation need be longer than from two to four inches, notwithstanding the very long incisions indulged in by foreign surgeons.

Dr. Charles R. L. Putnam spoke of a case in which he had been able to show the part played by movable kidney by making use of mechanical pressure produced by a belt having an egg-shaped pad.

Dr. A. A. Berg said that in palpation of the full gall-bladder the surgeon often failed to detect the presence of stones. He had found that in all cases in which there was a mucous discharge from a gall-bladder fistula that there was obstruction in the cystic duct. The obstruction at the time of Dr. Goelet's first operation must have been either in the cystic duct or else he did not detect the presence of the stones because of having palpated the gall-bladder without previous aspiration.

Dr. Gallant said that he had advocated the use of a special corset to determine whether or not jaundice was due to a movable kidney. His efforts had been directed toward holding up the kidney by increasing the intra-abdominal pressure.

Dr. Morris said that American surgeons were accustomed to make use of much shorter incisions than were employed by foreign surgeons, a practice which should be commended.

Dr. Goelet said that he had done a cholecystotomy in the first instance with the object of sparing the patient from the added danger of a cholecystectomy. The gall-bladder was palpated before and during the operation, and the finger was introduced after the gall-bladder had been drained in order to be sure that at that time there was no stone present. The cystic duct appeared to be closed at the time.

---

## THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

*Annual Meeting, Held October 26, 1903.*

Wendell C Phillips, M.D., President.

**Officers Elected.**—*President*, Dr. Wendell C. Phillips; *First Vice-President*, Dr. George M. Swift; *Second Vice-President*, Dr. Henry S. Stearns; *Secretary*, Dr. John Van Doren Young; *Assistant Secretary*, Dr. Edmund Prince Fowler; *Treasurer*, Dr. John S. Warren; *Censors*, Drs. Joseph Brettauer, Floyd M. Crandall, Charles N. Dowd, William H. Park, and John Van Der Poel.

**Instruction in Sexual Hygiene.**—In the report of the Committee on Hygiene, read by Dr. W. S. Thomas, this subject was considered at some length. The committee sent out a circular letter with the object of ascertaining if instruction in sexual hygiene was given in many educational institutions. Thirty-nine replies were received coming from universities, boards of education, private schools, etc. The opinion of educators seemed to be about

evenly divided in regard to the expediency of giving such instruction to the older boys, not that they were not mindful of the importance of such teaching as a means of preventing venereal disease, but because of the great difficulty experienced in selecting a proper method. Nowhere in Greater New York is instruction of this nature given, and in order that it could be introduced into the public schools action of the entire board of superintendents and of the Board of Education would be necessary. The committee was of the opinion that the means to accomplish this desirable end were so beset with difficulties that it was not advisable to recommend that such instruction be given generally in the schools of this city.

**Report of the Milk Commission.**—Dr. R. G. FREEMAN presented this report. He said that certified milk had been extended to certain new dairies during the past year and withdrawn from others. This milk was now produced on ten farms, and, as a rule, it showed a very low bacterial content. The milk was sold at ten or twelve cents per quart. The "inspected" milk retailed at eight cents per quart, and, at the present time, only 1,500 quarts were sold daily. There should be a large demand for this milk, because it was sold at the same price as ordinary milk, and was much cleaner. No certified cream had as yet been placed on the market, but it was hoped that this deficiency would be remedied in the near future. The certified milk had been examined every week, and also at irregular intervals, and it was reassuring to note that these unexpected inspections had failed to reveal any increase of the above average bacterial content. A new cap for sealing the bottles had been adopted, which prevented tampering with the milk. The inspector's services cost $730 a year, and the traveling expenses amounted last year to $499.96.

**Prosecution of Illegal Practitioners.**—CHAMPE S. ANDREWS, Esq., presented the annual report of the Counsel of the Society. In the past year a special effort had been made to stop the practice of several of our leading newspapers of inserting outrageously offensive advertisements, particularly of those posing as clairvoyants, but really doing business as abortionists. Altogether, thirty-one persons were prosecuted and thirty-one were convicted. The aggregate of the fines amounted to $2,490.

Hon. JULIUS M. MAYER, Justice of the Court of Special Sessions of New York County, discussed the report. He said that, under the law of this State, there was no definition of what was meant by the practice of medicine, a deficiency that must sooner or later be made good. He suggested that the minimum punishment now provided for the first offense should be abolished. At present the courts could not impose a sentence of over six months' imprisonment, *or* a fine of $250 for the first offense. No such limitation should be made, because many of the cases presented features which warranted a very much more severe punishment. The law in this State relating to misdemeanors usually provided that the punishment should be one year's imprisonment or a fine of $500, or both, according to the discretion of the court. With some of these offenders the combination of fine and imprisonment was very much more effective than either alone. He wished particularly to emphasize the fact, that there would be very much less of this crime against the public if these illegal practices were not kept before the public eye by the advertisements inserted in several of our leading newspapers. Great difficulties were experienced in securing the necessary evidence because, it must be remembered, the courts had held again and again that the testimony of a detective must be corroborated. Most quacks were well aware of this, and were very careful not to allow more than one person to consult them at a time. It was very rare, in this class of cases, that the victim could be prevailed upon to testify. The speaker declared that no matter how meritorious the work conducted by a public or quasi-public society, such society should not receive the fines imposed in a court of law in any criminal case. He was well aware that in the case of the Medical Society of the County of New York these fines did not aggregate more than half of the expenses of conducting such prosecutions, and that its motives were excellent; nevertheless, the principle of receiving such fines was all wrong. Again, in some of the most successful and praiseworthy prosecutions this society did not get a cent, simply because the punishment was imprisonment and not a fine. He hoped the two county medical organizations would come together in harmony and peace, and would unite, not only their efforts, but their funds, in such a way as to enable them to employ high-class men and secure the necessary prosecutions without allowing the specific fines from specific cases to flow into the society's treasury.

## Therapeutic Hints.

**Prolapse of Kidney.**—The common symptoms of prolapsed kidney are vertigo, syncope, palpitation of the heart, insomnia, hysteria, neurasthenia, and irritability of the bladder. These symptoms are dependent mainly on gastrointestinal disturbances, due either to irritation of the solar plexus or to direct traction on the duodenum by the kidney. There is often pain in the region of the kidney and in the ovarian region, back, thighs, and head. Such patients are never relieved until the kidney is lifted from the colon and permanently fixed in its normal position. Operation is the best treatment, because temporary relief of symptoms from belt or corset does not cure, and pressure from these supports provokes undesirable irritation and sometimes nephritis, while the operation is devoid of danger and the cure is permanent.

—GOULET, in *Annals of Gynecology*.

**Suggestions in Surgical Practice.**—Never sew up at once a wound that is badly crushed, or in which, for any reason, healing by first intention is unlikely to occur. Thoroughly disinfect, place the parts at rest, and remember the value of secondary sutures.

In injuries of the hands or feet, never be too eager to do a classical operation. Preserve as much palmar or plantar flap as possible, and be guided by the idea of restoring the best possible function, regardless of appearance.

Always wash and disinfect the meatus and glands in all cases in which instruments are to be introduced within the urethra. It serves little to have carefully sterilized the instruments if they are to be infected by contact with these parts.

Pressure on the edges of wounds with pledgets of cotton or gauze suffices to stop bleeding, as a rule, from all but the larger vessels. The assistant is less in the way than a number of artery forceps would be, and there is no bruising of tissues, hence more perfect union.

In vulvitis of little girls, always examine the discharge bacteriologically, but avoid awakening suspicions that may be unfounded. It may be due to thread-worms, dirt, incontinence of urine, eczema of the pudenda or strumous ulceration, as well as to gonorrhœal infection. A blunt retractor can be readily made by bending the handle of a spoon to the proper angle. A sharp retractor is made in the household by bending inward the tips of the tines of a fork. —*International Journal of Surgery*.

**Circumcision.**—I wish to enter a protest against the custom of universal and indiscriminate circumcision of male infants. It should be the duty of the attending physician to reflect the prepuce of all male children when they are a month old, relieve the corona glandis of the smegma present, anoint it with olive oil or vaselin, and replace the foreskin. This should be repeated two or three times a month by the mother, and the parts cleansed.

—H. E. TULEY, in *Archives of Pediatrics*.

**Cancer**, being a disease of the constitution, cannot adequately be dealt with by the knife only. Surgical measures need to be supplemented by medical and dietetic

treatment which attack the root of the mischief. It is then possible that a cure may result. Conditions favorable to the development of the disease are, living in insanitary houses or upon a damp soil.

—Dr. BELL, in *British Journal of Nursing.*

**Antispasmodic in Cases of Asthma.—**

℞ Tinct. hyosciami.....
Spir. meth. comp.....ää 30
Potassi iodidi..... 15
Syrupi..... 30
Aquæ menth.....pip. add 15.0

M. S. Two teaspoonfuls in water every two or three hours. —F. M. MOORE.

**Dropsy.**—A dry diet is recommended to patients with renal dropsy. Restriction of fluid in such cases does not interfere with elimination, and it does help to remove dropsy. —HUTCHINSON.

**Nosebleed.**—Grasp the nose between the thumb and forefinger, and press backward against the alveolar border of the maxilla, and downward against the teeth. This compresses the lateralis nasi and septal arteries. Satisfactory results also follow the use of tannin and acetanilid.

—*The Laryngoscope.*

**Elixir of Terpin Hydrate.—**

℞ Terpene hydrate..... 2 gms.
Alcohol..... 80 gms.
Distilled cherry laurel water..... 5 gms.
Garus's elixir..... 20 gms.
Syrup of tolu.....
Syrup of diacodion. } of each.....100 gms.
Distilled water, q. s. to make.....330 gms.

M. Tablespoonful, twice to four times daily for bronchitis, etc.

**Chronic Pharyngitis.—**

℞ Sodii boratis..... ʒii
Tinct. myrrhæ..... ʒi
Infusi cocæ foliæ..... ʒviii

M. S. Use as a gargle every two hours.

Or,

℞ Potassii chloratis..... ʒiiss
Infusi rubi fol..... ʒiv
Infusi cochleariæ..... ʒss

M. S. To be used as a gargle.

—*Journal des Praticiens.*

**Leg Ulcer.—**

℞ Zinci oxidi..... ʒx
Gelatin..... ʒv
Glycerini..... ʒi
Aq. destil..... ʒiiss

M. S. Apply with a soft brush, changing the dressing every three to ten days.

**Coal Gas Poisoning.**—Two ounces of peroxide of hydrogen can be given per rectum, or by the mouth, and repeated as required.

A piece of ice inserted in the rectum often has a quick effect upon restoration to consciousness.

—*Merck's Archives.*

**Rubefacient in Asthma.**—Sir James Sawyer recommends ethereal tincture of capsicum, solution of ammonia, turpentine, linseed oil, in equal parts.

**Chronic Rheumatism.—**

℞ Pulv. guaiaci resinæ..... ʒi
Potassii iodidi..... ʒi
Tinct. colchici seminis..... ʒiii
Syr..... ʒii
Aq. cinnamomi.....ad. ʒvi

M. et ft. mist. S. A dessertspoonful to a tablespoonful twice daily.

### TRAUMATIC LOCOMOTOR ATAXIA.

By ALLAN McLANE HAMILTON, M.D., F.R.S.E.,
NEW YORK.

LOCOMOTOR ATAXIA is here used instead of tabes spinalis, which latter term must always be associated with an actual degenerative lesion of the posterior columns. When Duchenne adopted the former he undoubtedly, to some degree, had in mind the clinical rather than the pathological character of the affection, and for many years it was made to include symptoms due to lesions both of the cerebellum and other parts, as well as the cord itself. In these days of advanced neurology the first are usually recognized without difficulty, and given their proper place, and are differentiated from the consistent symptomatic picture which is the true tabes. In the present connection it is adopted for convenience to include the various sensory and ataxic states, which may be explained by injury of the posterior nerve roots without necessary involvement of the cord itself; by toxæmic or consecutive lesions, or by peripheral or hysterical anæsthesia which gives rise to the incoördination and other of the symptoms which belong to the grave disorder. The possibility of injury as the cause of ataxia has frequently arisen in connection with litigation, and many cases have gone into court presenting a trauma dependent upon a railway accident which has been alleged to be the sole etiological factor. These cases do not seem to have been considered as true examples, for there is almost complete unanimity of opinion that genuine tabes—that is, the form with arthropathies, optic nerve atrophy, Argyll-Robertson pupil and gastric crises—can have no such origin; but in most instances is explained by syphilis. It has been maintained that when the symptoms develop in a conspicuous manner immediately after an accident it is probable that they have been expressed in a minor degree for some time before. and have not been recognized by the patient or his physician; or else have been mistaken for the expression of some other affection. In other words, they are the lighting up of a long dormant affection. Walton of Boston, whose industrious researches in this field of medicine are entitled to the highest credit both for their thoroughness and originality, some years ago investigated all the alleged traumatic cases, but was unable to find one entirely uncomplicated. Bailey while reporting a case in which the appearance of a number of classical symptoms almost immediately followed a fall upon the buttocks, and in which there was no history of syphilis whatever, is as much in doubt as others about the relation of trauma to tabes inclining to disbelieve in the possibility of such a connection. The writer, whose experience has been large, while perfectly convinced that a consistent and progressive case of the disease as a result of injury is practically unknown, has seen so many patients in whom the trauma either lighted up a spinal syphilis, or gave rise to a group of symptoms due to nerve root injury, or consecutive to spinal laceration, that he does not feel inclined to dismiss the possibility of a pseudotabes which may very closely resemble the form which is universally supposed to be so distinct an entity. It need hardly be said that rapid local tissue destruction, or its aggravation in connection with syphilis, is often due to excessive use of alcohol, and doubtless violence when suddenly applied is in some cases capable of rendering a long standing and inactive syphilitic deposit capable of producing local toxæmia and resulting mischief in the cord.

Although Marie, I am informed, performs lumbar puncture in all his cases of tabes as a routine diagnostic method, and finds a varying degree of leucocytosis in commencing tabes, I am not aware that anyone has in non-syphilitic cases made such an examination to determine the early indications of this striking disease. Possibly such changes indicating the establishment of inflammatory action might be easily found in this as well as other kinds of myelitis, for the procedure is not a dangerous one and causes little embarrassment. Those familiar with the affection, and whose experience has been at all extensive have recognized a respectable number of irregular cases which not only depend upon some cause outside the spinal cord itself but in its vicinity, besides those commonly known. The *pseudotabes* of Gilles de la Tourette, Pitres, Petit, and others is characterized by the incomplete nature and development of symptoms, and by the possibility of cure, and Kowaleski reports a case in which symptoms attributed to tabes disappeared in twenty-seven days after hydrotherapy and rest. Finally there are hypochondriacal or hystero-hypochondriacal cases in which the symptom complex is striking, but, of course, lacking in completeness, and when the psychic element is present. These are the so-called curable cases which disappear speedily after the use of "goat lymph" or specially made shoes, and many are the marvelous recoveries which are just now widely advertised by ingenious quacks, for it would appear that at present what may be called *tabophobia* is unusually common, and many ordinary forms of lithæmic hypochondria are made to masquerade as locomotor ataxia.

Reference need hardly be made to the familiar symptoms of tabes, a disease which is notably chronic, lasting sometimes even for forty years and not in itself materially shortening life. Beginning with a preataxic stage, the expressions of which in the beginning are often mistaken for those of other affections its early diagnosis is by no means easy.

This is especially true so far as the disturbances of sensation are concerned which depend upon the encroachment of the disease in a neighborhood where it involves the posterior nerve roots, the meninges, and at first parts adjacent to the cord; although later there is a central explanation for others of greater gravity. Not only do we usually with certain changes of wind, especially where the barometric pressure is low, find the occurrence of sharp, lancinating or fulgurating pains, as a rule at first in the lower extremities, with painful residual areas and points, but dysæsthesia and tactile

anæsthesia, which may involve the plantar surfaces, preventing the individual from standing unsupported when his eyes are closed (Romberg's symptom), and sometimes contributing to the production of the ataxic gait. Pupillary insensibility to direct light stimulation, with conservation of power for accommodation (Argyll-Robertson symptom) diplopia; dysuria, sexual weakness constipation, joint weariness, loss of knee-jerks and other deep reflexes, arthropathies. etc., are followed by the characteristic ataxic gait, difficulty in turning, or descending inclined surfaces or steps, sudden inhibition of muscular power through fear, gradually developing optic nerve atrophy while subsequent paralysis and atrophy of the affected muscles, and possible exaggeration of the knee-jerks occur when other parts of the cord and the posterior columns are invaded by the degenerative process. True tabes is manifested by a certain similarity of symptoms, the nature of the pains and their method of occurrence being very much alike in a given number of cases which are compared, and they are usually associated in active cases with gastric, laryngeal, rectal or vesical crises, although in many cases there may be little or no pain. The same is true of the distribution of anæsthesia, which, if plantar, is more commonly of the perineal type or, if occurring in the upper extremities, is usually found on the ulnar side of the forearm and hand. The arthropathies, although comparatively rare, cannot by any well-informed physician be long mistaken for any other form of joint enlargement, even when occurring after injury they have a character of their own, and are, as Charcot first pointed out, quite inseparable from spinal cord degeneration, and when found, in every case, have been preceded by some of the peculiar symptoms of the spinal affection. In some cases of fracture, an accident to which tabetics are prone, it will not be difficult to get a history. The same may be said of perforating ulcers and of the earlier trophic disorders which, by the uninitiated, are supposed to be due to ordinary conditions. The gait has a certain uniformity and the patient brings his heel down first, there being some spasticity, and it is only in the old cases that the disorderly titubation, which is characteristic of dementia-paralytica, is found. These facts are thus fully referred to because in the irregular cases to which attention has been directed one must be impressed by a certain peculiar disorder in progression. In most of the reported cases which are claimed to be traumatic there is, with but few exceptions, a history of sudden development and irregular progress, and usually a very rapid development of symptoms, the preataxic stage being short. The dominant sensory expressions of ordinary tabes do not appear to be important in this form, and the pains are rarely so intense as to need morphine. In cases which have come under the writer's notice, girdle and radiating pains have caused more suffering than those of the extremities, and even when the disease has advanced there have been no abdominal crises. The anæsthesia has been irregular, and rarely bilateral, except in one non-traumatic hysterical case, while in another the anus and lower rectum were anæsthetic. While the knee-jerks were lost, the writer has never found the lost pupillary reflex, and in no case has there been any optic nerve atrophy or neuritis. One of the striking and suggestive differences is found in the gait, which is far more disorderly in locomotor ataxia after trauma than in tabes of organic origin in which there is usually a syphilitic basis. While the heel impact and the trajection that belong to the ataxic gait are present, there seems to be at an early date a great deal of unsteadiness and disorder, thus resembling the Friedreich type, and when the patient progresses the action of the quadriceps is exaggerated so that the knee is lifted higher than it is in the ordinary case of tabes, and there seems also to be a species of lateral wobbling or unsteadiness. This lifting is not to be confounded with that associated with certain forms of peripheral neuritis. True arthropathies are not found in the cases to which reference is here made, and when present, as Bailey and others have pointed out, there is undoubtedly an antecedent history, and they are not attributable to injury alone. The traumatic examples that are apt to be met with are of three kinds: (1) Hysterical and neurasthenic forms—the pseudotabes of the French writers. (2) Residual cases in which, after laceration of the cord, there remains a lesion of the posterior columns. (3) Cases in which, through wrench or twisting of the body, there is tension or actual torsion of the posterior spinal nerves, traumatic neuritis with predominating sensory symptoms. (4) Cases due to initial injury with a recurrent hyperæmia and pressure.

Hysterical locomotor ataxia is, of course, attended by none of the inevitable deep indications of central degeneration, which belong to true tabes; yet it may present the sensory and motorial indicia of the real affection, which are calculated to deceive some people. The anæsthesia, as a rule, is much more profound and is rather sudden in its appearance, and the ataxia is coincident and sometimes marks a sharp début. There are never preataxic, lancinating pains, but ill-defined dysæsthesia, and there is, as a rule, a neurasthenic basis with the general familiar symptoms. In a case seen by the writer analgesia existed, and was complete and extensive. While the superficial reflexes were abolished in response to irritation of the anæsthetic area, the knee-jerks were preserved and the pupils reacted normally to light. The ataxia was confined to the lower extremities, and if the patient closed her eyes she became agitated, emotional and dropped to the ground, crying aloud as she did so. There is in tabes itself a period of swaying and toppling, however short, which precedes the fall, and the patient strives to balance himself by laterally extending his arm; but there was nothing of the kind with this patient. There was a vesical spasm and considerable discomfort, but neither retention nor incontinence. The only visual disturbance was asthenopia and the eye field was normal. She had before presented certain stigmata of hysteria, and was of a nervous family—her brother, with whom she lived, having had tabes. A trifling fall was the alleged cause, but undoubtedly there was some imitative tendency as well. After a few months' treatment a cure was effected, principally through the use of the induced current, the patient being isolated meanwhile. The entire duration of the symptoms was less than a year.

In contrast the case of J. R. G. is interesting, because of the rapidity of its progress and its direct connection with an undoubted spinal injury—possibly a laceration. It was impossible to determine the existence of syphilitic infection, and it is the writer's opinion that his present condition dated from an accident in the Harlem tunnel, which occurred January 8, 1902, when there was a rear-end collision, and the patient was thrown forward, receiving a severe wrench and possibly a blow in the dorsal region, for there was resulting severe and obstinate pain which lasted some time. According to his story he was able to leave the car but was unnerved and rapidly became neurasthenic and demoralized. After this he did not dare to do anything requiring mental or physical effort and wa

timid to a degree. He could not walk on a fallen log over a stream when in the country, and found it impossible to move about his room at night in the dark, or place his hands over his eyes when he washed his face, without pitching forward. In April or May, 1902, he began to have "rheumatic pains" and a painful girdle at a level of about the edge of the lower ribs. He has had fulgurating pains in his legs since May, 1903, and pretty much all of the year 1902 he had trouble with the bladder, passing his urine very slowly. His general break-up was so great that he went abroad in the spring of 1903, where a diagnosis of locomotor ataxia was made by Purves Stewart of London. The doctor writes me September 26: "his pupils are rather small, but react normally to light and on accommodation. The optic disks and cranial nerves are normal. He has no loss of sensation on the face, trunk or limbs to lightest touches or pricks; but along the ulnar borders of hands and inner sides of soles, including the great toes, pinpricks, though felt acutely, are accompanied by a peculiar tingling sensation; pressure on the ulnar nerves behind the internal condyles is painless. The sense of position on passive movement is impaired at the toes, ankles, and hips, fairly good at the knees. There is distinct hypotonia of the calf and the hamstring muscles. The gait is ataxic, his handwriting is deteriorating, and he feels himself clumsy when buttoning his clothes or when picking small objects out of his pockets. The knee-jerks, Achilles jerks, and supinator jerks are absent. There is some delay in micturition and he is sexually impotent." Upon his return from Europe the patient consulted me, when I found all these symptoms, and evidently an increase of the ataxia for he could only ascend and descend the stairs with the greatest difficulty, and he was in a very nervous and anxious condition, and so weak that he was obliged to spend most of his time in bed. There is the same hypotonia of the muscles of the hand as exists in the lower extremities, and he is unable to use them now at all except for gross efforts. In this case the same extreme disorderly walk is found that has been referred to when speaking of other traumatic examples, and the mental element is highly suggestive of that which belongs to the so-called traumatic neurasthenia. So far he has not responded to treatment, and it has been found necessary to direct complete rest, and forced feeding.

Two cases of a somewhat interesting nature, from the fact that certain symptoms were recurrent in both, that there was a traumatic history, and that these recurrences followed undue exertion clearly show that there is a form of traumatic pseudotabes with obscure pathogeny, but not necessarily classic posterior column degeneration. J. M. is now, in 1903, fifty years old, and has been a marine engineer for a long time. He is at present chief engineer of a coast steamer. His general health up to 1884 was exceedingly good, as were his habits, and it is impossible to find a history of syphilitic infection. In that year he fell from an upper deck into the fire-room of his ship, about twenty feet below, landing upon both feet. Strange to say, beyond a slight concussion, some tingling and burning of his lower extremities, and a slight loss of power, there were no immediate consequences. In a few days, however, he began to have pains suggestive of irritation of the posterior nerve roots, rather general analgesia of the legs and feet, myelasthenia, insomnia, and attacks of lumbar pain.

Micturition was frequent and difficult, and there was slight tenesmus after the act. His sexual power diminished; he became neurasthenic and was obliged to give up his work. In 1886 these symptoms were supplemented by ataxia and difficulty in coördination, and his walk became "wobbly" and disorderly, there being at the same time great irresolution and timidity in finding his way about the streets.

He presented himself at the Hospital for Ruptured and Crippled in this city in the summer of 1887, when he came under my care in the outpatient department. Both knee-jerks were evoked with difficulty, but the pupillary and other reflexes were but slightly affected if at all. Under absolute rest, spinal cauterization and cod-liver oil he recovered in eight months, so that he was able to return to his work and made regular trips from New York to Havana until the spring of 1899, when he contracted a Tampico fever and came to his home in Orange, N. J. In September of that year I saw him in consultation with Dr. Phelan, and found him bedridden. It was stated that he had been unable to walk for more than a month because of an extreme degree of ataxia that had rather suddenly appeared during convalescence, and when he made undue muscular exertion. When helped out of bed he walked with great difficulty, raising his knees and legs very high and applying his heels to the ground in a jerking way, quite different from the gait of true tabes. There was no paralysis of motion, but there was tactile and pain anæsthesia of the plantar surfaces, the outer toes of both feet being specially affected. He had severe gastric and visceral pains suggestive of crises, and at the time of the visit there was retention, and it was necessary to use the catheter. Both knee-jerks were still absent. After cauterization and ergotin he began to improve, and on January 2, 1900, he was able, after a few weeks of shore duty, to take charge of a new steamer, and since then has been, with the exception of slight gastric disturbance, a well and strong man.

The second is that of G. L. K., a traveling salesman of thirty-three years, who has never had syphilis, and his habits are good. He smoked moderately and occasionally took beer or whiskey. About sixteen years ago, after severe muscular action in lifting a heavy tray from a sample trunk, he suffered a sudden lumbar pain which disappeared under simple remedies and was followed, as he said, by some swelling of knees and feet. This, in turn, disappeared, leaving him with a sense of weakness, and a difficulty in locomotion which was due to ataxia. There do not appear to have been any leg pains or any bladder disturbance. In a short time he regained his ordinary vigor, resuming his occupation as commercial traveler until 1897. While in Columbus, Ohio, in that year, he again performed an uncalled for muscular act of a violent nature, which was followed by numbness in both limbs, which extended from the knees downward, the soles of his feet being, perhaps, the most insensitive. According to his story there was a variation in the extent of the pdysæsthesia and a sort of intermission, there being a period of normal sensibility, which would last for four or five days, and was followed by an absolute loss of feeling. After a week or two of this, his gait became affected, and it was with extreme difficulty that he could walk at all, because of the lack of coördination. He recovered also from this attack in a few months, and continued apparently in the best of health until eight weeks ago, when he began to have characteristic pains in both legs, which shot up through the feet; there were pains as well on the right side of the head and right arm. There was, for a month or so, some numbness in both plantar surfaces, but this was

not permanent. There was at times an imperative desire to urinate, but no other bladder symptoms. There was no constipation.

No Argyll-Robertson symptoms but both knee-jerks were gone. His gait showed a well-marked ataxia, and when he walked he planted his feet far apart, tottered and staggered, but could stand with his eyes closed. Most of the motor symptoms were present, so far as the lower extremities were concerned, and his was apparently an exceedingly easy case for diagnosis. The history, however, of the two subsequent attacks and the rapid *début* of the present one impressed me, as I learn it had Dr. Osler.

From June, 1900, when I first saw him, he has continued to improve under the use of ergotin—tri-weekly burning with the Paquelin cautery, which was substituted by blistering with vesicating collodion during his absence from New York, and absolute rest. The treatment was kept up by his physician in Cleveland, Ohio, with the result that by autumn his sensory symptoms had absolutely disappeared and his gait was but slightly embarrassed. He was able to go up and down stairs without difficulty, walk about in dark places, and do a great deal of work. During the winter of 1901 he came to New York again, and I was unable to find any ataxia whatever, although the knee reflexes were still absent, and his pupillary condition was less sluggish than it had been. At one of these visits I found a painful crop of herpes situated in the inguinal region and upon the dorsum of the penis. There were also one or two spots upon his neck and back. These were followed by great local irritation and some neuralgia. There were absolutely no other trophic or cutaneous changes. Up to the present time, October, 1903, there has been no return of the trouble.

The litigation cases are often fictitious, and might be at once dismissed from consideration were it not for the tendency which so often exists to thrash out medical symptoms in court by laymen who naturally know nothing about their significance. Such a case was that of Miss Z., who sued the Metropolitan Street Railway. The medical testimony for the plaintiff was given by three physicians whose diagnosis of "locomotor ataxia developing from myelitis" certainly is an illustration of the weakness of certain kind of expertism. It was claimed that in an accident which occurred in February, 1896, she received a blow on the back, that she was confined to her bed immediately and there remained for fourteen weeks. One of her physicians testified that there was paralysis of both lower extremities, entire loss of sensation on the right side, *increase of knee-jerks* and ankle clonus. The right leg was smaller than the left, "the reflexes of the eye do not respond the way they should to *light* or *distance*." Another who examined her testified that the disease was "myelitis running into a form of locomotor ataxia subsequently." He found that "the so-called *patella reflex was very much diminished*." There was "inversion of the foot, due to loss of power of the extensor muscles of the leg, loss of sensation, more particularly on the outer side of the right leg, diminution of the size of the right leg and *ankle clonus*. The alleged loss of sensation found appears to have been an analgesia. Another medical witness diagnosed the case as myelitis, and found partial paralysis of the right extremity, atrophy, contracture, ankle clonus, *exaggeration* of knee-jerks, loss of sensibility to touch, temperature, and pain. All these examinations were made at about the same time, and not only was there a conflict in regard to the reflexes, but the first physician appears to have had rather confused views as to the eye reflexes and their significance; there certainly was no evidence of tabes.

The patient was seen by two doctors for the company, who found absolutely nothing at all, and regarded the case, as one of malingering.

It appears from the testimony that the young woman had gone to a seaside resort and was actually dancing at the time when she was alleged to be incapacitated and on crutches.

## INTRAVENOUS INJECTIONS OF COLLOIDAL SILVER IN THE TREATMENT OF ERYSIPELAS.

By WARREN COLEMAN, M.D.,
NEW YORK.
PROFESSOR OF CLINICAL MEDICINE, CORNELL UNIVERSITY; ASSISTANT VISITING PHYSICIAN TO BELLEVUE HOSPITAL.

The favorable reports which have appeared in France and Germany on the use of intravenous injections of colloidal silver in various infective processes induced me to give the drug and the method a trial during the past summer. The results have been sufficiently encouraging, especially in erysipelas, to warrant publication of the cases.

I am greatly indebted to Dr. Benj. F. Tilton for placing the cases in the Erysipelas Pavilion at my disposal.

The history of the introduction of colloidal silver as a therapeutic agent and its administration, both by inunction and intravenously, have been so fully described by Netter[1] and Credé[2] that it will be unnecessary to cover the ground again.

Colloidal silver has been used with varying success in septic processes generally, as pyæmia, septicæmia, surgical infections, septic complications of infective diseases; pneumonia, carbuncle, anthrax, gonorrhœa, etc. Schmidt[3] has reported three cases of erysipelas successfully treated with it.

In the present series of cases the colloidal silver has been used intravenously in doses of 5-10 c.c. of a 1 per cent. aqueous solution. It is claimed that solutions of colloidal silver will keep for months without deterioriating, but I have had small quantities of the solution made as occasion required. The fresh solution is of a deep brown color, becoming grayish as it deteriorates.

All who have used colloidal silver agree that it is harmless. Formerly chill constantly followed the injections—it occurred in several of my cases—but it is claimed that colloidal silver as now manufactured does not cause chills. In some of my cases (not erysipelas) the temperature rose 2° or more within six hours after the injection. Only in one case did the slightest evidence of cardiac depression occur and that was not serious. I have made no attempt to study the blood changes following the injections.

*Technique.*—Any syringe with a capacity of 10 c.c., which can be efficiently sterilized, may be used for the injections. It is advisable that the syringe be used only for this purpose, as it lessens the chances of accidental infection. The syringe which I have found most satisfactory is the Edson antitoxin syringe, in which the piston consists of a metal plunger covered with rubber tissue. A new piece of rubber may be used for every injection.

Any large vein may be selected for the injection. The veins at the bend of the elbow are the most convenient. The site of the vein should be sterilized as for an operation, and covered with bichloride or carbolic gauze until the needle is ready for insertion. Before the dressing is removed a bandage should b

tied about the arm to bring out the veins. If they do not appear readily, the arm may be allowed to hang over the edge of the bed for a few minutes. In no case have I found it necessary to cut down upon the vein. A hypodermic-size needle is the most convenient, and the vein can be entered more easily if the eye of the needle is uppermost. The syringe should be held as nearly as possible in the long axis of the vein. If the vein shows a tendency to roll from under the needle, slight axis traction below the site of insertion will steady it. It is generally easy to tell when the needle has entered the vein by the disappearance of resistance before it. In fact, the needle can often be felt to "pop" into the lumen of the vessel.

If doubt exists, the piston may be slightly withdrawn and a small quantity of blood sucked into the syringe. Of course all air should be removed from the syringe and needle before the needle is inserted, and even then it is advisable to incline the syringe so that any contained air will rise to the piston. The contents of the syringe must be injected slowly. The vein should be covered with sterile gauze and bandaged rather tightly immediately after withdrawal of the needle, otherwise it may

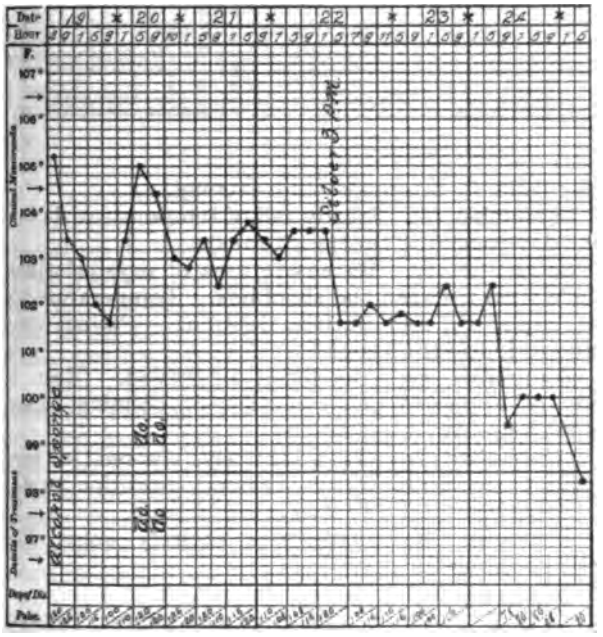

Chart No I.

bleed through the puncture and form a little hæmatoma. None of the colloidal silver should be allowed to escape into the tissues, as it produces a burning pain which may last for an hour or more. When this precaution is taken patients rarely complain of the procedure. Very little or no reaction, takes place at the site of the injection, and the same vein may be used within a day or two.

CASE I.—Thomas K., aged thirty-six years. Developed erysipelas after operation in another hospital for an old ununited fracture of the leg. Transferred to Bellevue.

General condition excellent. Heart and lungs normal. Ununited fracture of left femur, with incompletely healed operation wound. Presents a number of sharply defined erysipelatous areas along the margins of the wound, with reddish blotches scattered over the leg. Knee stiff.

August 22. Condition unchanged. Given 5 c.c. of a one-per-cent. solution of colloidal silver intravenously at 3 P.M. At five o'clock the temperature has fallen 2° F. The patient states that he feels much better and that all soreness in the leg and thigh has disappeared.

August 23. The inflammation in the leg has greatly diminished. No soreness. Patient continues to feel much better.

September 1. Wound healing nicely. No sign of erysipelas.

CASE II.—Richard F., aged thirty-four years. General health has usually been excellent. Appear-

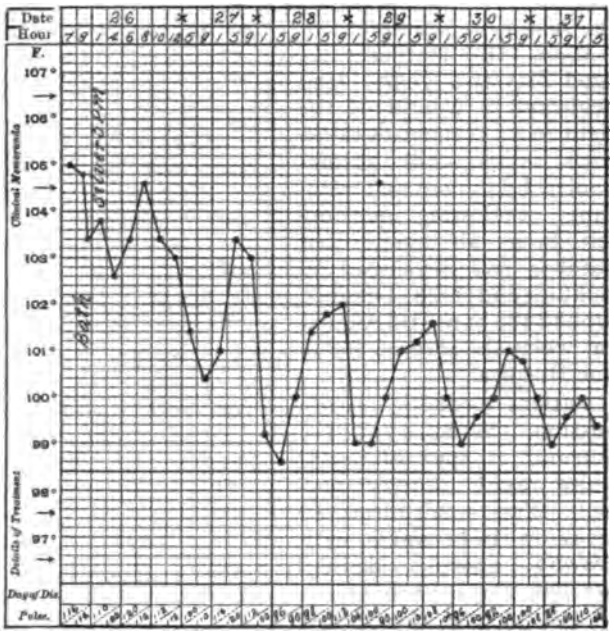

Chart No. II.

ance markedly alcoholic, though patient has drank but little for six weeks.

Something over two weeks ago patient received a slight wound of left ear. Six days before admission had a severe chill accompanied by vomiting and followed by high fever. Lay in the open fields for two or three days, then applied at several out-of-town hospitals, but was refused admission. Walked into

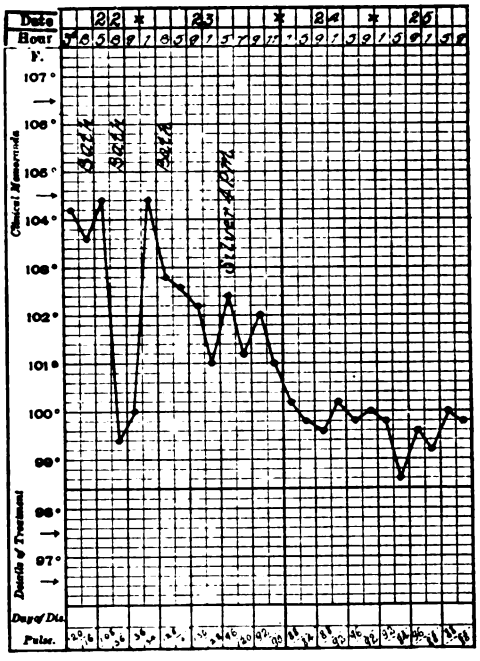

Chart No. III.

Bellevue Hospital on August 26. Heart and lungs normal. Face swollen, red and œdematous on both sides, but patient can still open his eyes.

August 26. Given 9 c.c. of a one-per-cent. solution of colloidal silver intravenously at 3 P.M.

August 27. Patient much better. Temperature down to 100.4° F.

August 28. Patient has developed slight pains in larger joints. Otherwise he feels well.

September 3. Still has some pain in joints. Erysipelas entirely gone.

September 4. Numerous purpuric spots about ankles.

Joints so painful patient cannot get up. The rest of the history is unimportant.

Case III.—Margaret R., aged fifty-two years. Had neglected a wound of the right foot. August 18 taken with severe chill accompanied by nausea and vomiting. Following morning felt lame all over. Red patches had developed on right leg and thigh. Dragged around the house till August 22, when she entered Bellevue Hospital.

Patient alcoholic on admission. Slight systolic murmur at apex of heart. Pulse rapid. Lungs normal. Two small ulcerated areas on right ankle, with brawny, sharply defined patches, varying from scarlet to purple, distributed over leg and inner surface of thigh. Right femoral and inguinal glands greatly enlarged.

August 22. A 10 per cent. carbolic acid dressing applied.

August 23. Inflammation greatly lessened. Symptoms of alcoholism have almost disappeared. Given 10 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M. At 6 o'clock patient had marked chill, accompanied by nausea and vomiting.

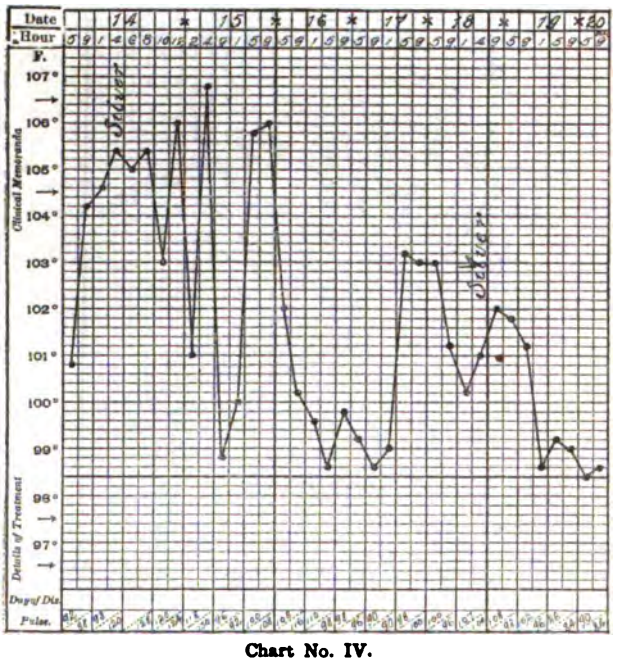

Chart No. IV.

August 24. Patient feels much better. Signs of inflammation greatly diminished. Temperature down.

September 3. Patient feels perfectly well. Local condition cured.

Case IV.—Rosie P., aged thirty-four years. No history obtainable, as the patient does not speak English.

September 14. General condition good. Entire face red and swollen, especially under the eyes. The redness is sharply marginated. Heart and lungs normal. Incontinence of urine and fæces. Given 8 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M. Has restless night.

September 15. Morning temperature 98.8° F.; up again in afternoon and evening.

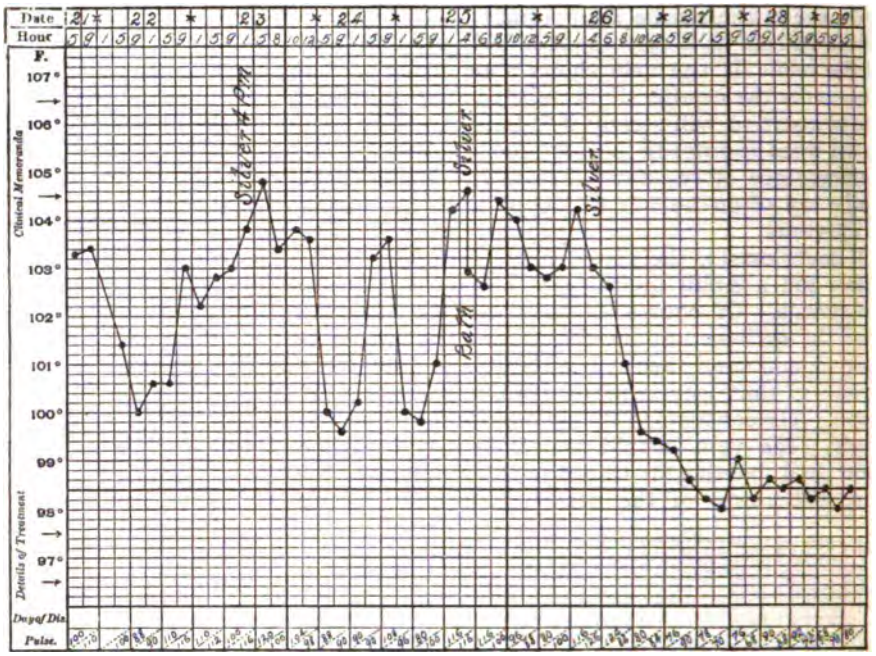

Chart No. V.

September 16. Steady fall of temperature during the day to 98.6° F. in the afternoon.

September 17. Extensive area of erysipelas has developed between the shoulders. Temperature up to 103.2° F., and patient delirious. Patient continues delirious all night.

September 18. Condition improved. Given 8 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M.

September 19. Face entirely cleared of erysipelas; back nearly so. General condition good.

September 20. Temperature normal.

September 21. Erysipelas entirely gone. Patient feels well.

September 27. Patient discharged.

Case V. John T., aged fourteen years. Noticed red spot on neck below left ear August 17. No history of wound or chill. Redness and swelling gradually extended up to left ear and eye. Walked into Bellevue Hospital August 21. General condition good. Heart and lungs normal. Sharply marginated scarlet swelling extending from left side of neck up over ear to margin of scalp and left upper eyelid.

August 22. General condition continues good, but erysipelas has extended. Left eye is shut and scalp is involved.

August 23. Condition same as yesterday. Given 7 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M.

August 24. Patient's temperature down to 99.6° F. Says he feels much better. Erysipelas has not extended; has perhaps subsided somewhat.

August 25. Swelling of left side of face more pronounced. Cannot open left eye. Fairly large area of erysipelas below right eye. Back of neck and upper part of thorax also involved. Given 7 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M.

August 26. Face not so swollen. Erysipelas has not spread. Given 7 c.c. of a one-per-cent. solution of colloidal silver intravenously at 4 P.M.

August 27. Temperature normal.

August 28. Erysipelas has practically disappeared. Patient out of bed.

I do not feel justified in drawing conclusions too confidently from the above cases, especially as the usual treatment employed in the hospital for erysipelas was not discontinued. Being convinced, however, by an experience including some 20 cases of various diseases, of the harmlessness of the method, I can recommend that it be tried in appropriate cases. Even if the injections do not benefit the patient, they will do no harm. In some of my cases not a symptom followed the injections. So impressed am I with the possibilities that the intravenous use of colloidal silver holds, that I am actively continuing the work upon cases kindly placed at my disposal by Professor Loomis.

In conclusion I wish to thank Drs. William Wilson, D. Miltimore, and R. M. Vose for their valuable assistance.

## CHRONIC CYANOSIS OF THE EXTREMITIES ASSOCIATED WITH POLYCYTHÆMIA AND SPLENOMEGALY.

By JOSEPH COLLINS, M.D.,
NEW YORK.
PHYSICIAN TO THE CITY HOSPITAL.

During the last few years there has appeared, from time to time, in medical literature, reports of cases of chronic cyanosis not associated with emphysema, organic heart disease, or poisoning from substances that reduce hæmaglobin. There are now eleven or twelve such cases on record to which I shall add one, possibly two, more. The first case seems to have been recorded by Vaquez in the *Bulletin Médical*, Paris, 1892. In 1899 Cabot published in the *Boston Medical and Surgical Journal*, December 7, 1899, the history of a case entitled "A Case of Chronic Cyanosis Without Discoverable Cause, Ending in Cerebral Hemorrhage," and in the same Journal, March 15, 1900, a second case. In 1901 McKeen published, in the *Boston Medical and Surgical Journal*, the history of a man afflicted with an unaccountable cyanosis, which, however, I am not entirely satisfied belongs to the form of disease to which the name constituting the title of this paper must, provisionally, be given. Last year Saunby and Russell of Birmingham reported a case in the *Lancet*, February 22, 1902, and recently Osler has published the notes of four cases in the *American Journal of the Medical Sciences*, August, 1903. Other cases that have been recorded are mentioned later.

The first case I saw (if it is a genuine case) was encountered in the City Hospital in the winter of 1902, but it did not occur to me that the cyanosis was other than an ancillary phenomenon of the disease from which the patient suffered, viz., an atypical form of spinal progressive muscular atrophy, until I met my second case. This patient was made the subject of a clinical lecture at the Post-Graduate Medical School last March. The case was not only what might be called an extreme example of the disease, but it shows that this peculiar association of symptoms or disease may occur in the young.

The patient, an Irish girl, twenty-four years old, employed as a domestic, states that she was in good health until her twenty-first year. She then began to complain of pain in the left side. She described the pain as a stitch which kept her from taking a full breath. The "stitch" would last a few minutes and then subside. This pain continued for about five weeks, during which period she was under treatment for neuralgia. About the same time she noticed, and it was remarked by others, that her hands and face got reddish purple, and that this discoloration did not disappear. There was no pain nor swelling with it, and it seemed to have no relationship to the "stitch" in the side, except that it came after it. In addition to the pain in the left side, she suffered at times from pain in the left shoulder, from peculiar pain in the back of the neck and base of the skull which she is unable to describe, but which was relieved by dry heat, and from syncopal sensation which, she thinks, came about once a week. She never became wholly unconscious in these fainting spells. During this period she was subject to attacks of vertigo, each one of which lasted about fifteen minutes. The attacks were so severe that she would have to sit. They recurred at varying intervals. During the past year these spells have diminished in frequency and severity until now they have practically disappeared. Other symptoms that have been troublesome are vertical and occipital headache, and occasional attacks of epistaxis. The latter she gets invariably when she has a "cold." At the onset of her illness she had frequent attacks of vomiting. At one time she says that this vomiting kept up for about a month, during which time she lost about fifteen pounds. Constipation has been a distressing symptom and is still troublesome. The pain in the side, which is the burden of her complaint, has always been worse in winter, so much so, that she has been obliged to give up service during the cold weather. In the summer she has always gained strength and has been fit for work.

Six months ago she had what was diagnosticated to be erysipelas of the left foot. The foot and the lower part of the leg took on a deeper reddish blue color, and it got puffy but not painful. There were no blisters or evidences of suppuration. The swelling lasted about a fortnight.

She came to my clinic to get relief from pain in her left side, described above, and general weakness. The cyanosis of the extremities had existed so long and without apparent inconvenience that she attached no importance to it. The appearance of the patient was striking, not to say startling. The face was suffused, the upper part particularly being of a reddish-blue hue. The whites of the eyes were nearly usurped by a deep reddish color, due to injection of the conjunctival blood vessels. This gave the eyes a very striking appearance, which was accentuated by a fairly well marked exophthalmos. The end of the nose and lips was likewise cyanotic. When the skin of the face is pressed upon lightly, no white mark appears, but when pressed hard, a white mark follows, which, however, disappears with great rapidity. The pupils, which are equal and regular, respond quickly to light and in accommodation. There is nothing abnormal to be made out with the ophthalmoscope. The surface temperature of the face is normal. The hands are of a deep, bluish-red color, the finger nails blue. There is no indication of trophic alteration in the nails or skin. The cyanosis extends to about an inch above the wrist, and then shades off through light red to the normal appearance. The skin itself is warm and dry to the touch. Pressure upon the hands is followed by white spots, which disappea with great rapidity. The feet and ankles present an appearance very similar to the hands, and need not, therefore, be described. There is no œdema or pigmentation. Examination of the heart shows that there is no dis

order of the valvular mechanism and no disease of the heart wall. The rhythm and the sounds are quite normal. There is some tachycardia, the pulse ranging about 90. The arteries are soft, the rhythm is regular but the vascular tension is evidently increased. There is no sign of emphysema or other affection of the lung, nor has the patient complained of shortness of breath or any discomfort attending breathing. The contour of the thorax presents no abnormality. There is no enlargement of the thyroid. On percussion there is to be made out an area of dulness or flatness over the entire lateral portion of the thorax extending from two inches below the inferior axillary border downward, to three inches above the crest of the ilium, the confines of the dulness laterally being a line drawn parallel to the anterior axillary line, one inch in front of it, and a line drawn from the posterior angle of the axilla to the inferior border of the scapula, and then to the crest of the ilium. The line of dulness anteriorly is not so straight as it is posteriorly. On a level of the ninth intercostal space the dulness extends farther toward the median line than the line spoken of above would confine. On palpation it is clearly evident that the cause of the dulness is an enormously enlarged spleen. It can be felt very distinctly, the surface smooth, the edges rounded. Whether or not the pancreas is enlarged I am unable to say positively, but I believe it is. The fact that the patient has attacks of ravenous appetite inclines me to that opinion, and the change in the outline of the area of flatness at the level of the pancreas tends to confirm it. There is no appreciable enlargement of the liver.

Examination of the urine showed it to be entirely normal in appearance and constitution. At no time have casts of any sort or other abnormal constituent been found, although it has been analyzed often and carefully. Examination of the blood shows hæmaglobin, 110 per cent.; erythrocytes, 9,821,000; leucocytes, 17,800; slight leucocytosis. Differential count of the leucocytes shows polynuclear and transitional, 73 per cent.; large and small mononuclear, 26 per cent.; eosinophiles, ½ per cent.; no myelocytes. The blood flowed very slowly from the stab of the ear and the finger was quite black. The first thing that impresses one in viewing a drop of blood under the microscope is the enormous number of red blood cells. They form rouleaux that have a firm appearance. The red blood cells seem to be of normal size, and diligent search, both on the part of Dr. Nathaniel Bowditch Potter, who kindly examined the blood on one or two occasions, and myself failed to reveal any nucleated red cells. On one occasion I was able to observe clotting of the patient's blood from an epistaxis. It entered the jelly stage in a small hand basin in less than four minutes, and coagulation was not attended with the slightest formation of buffy coat.

Such was her condition at the time of my first examinations, and it has not changed materially since, except that she is not so strong as she was. She gets out of breath on going up stairs, and she has noted that she perspires much more freely than formerly. She does not suffer from pain in the side as much as she did during the winter, and she says that during the summer she does not have much pain. The menstrual function seems to be undisturbed, and the flow is of the customary color and duration. Although the bowels are constipated, digestion seems to be normal. A short time ago a number of ulcers about the size of the thumb nail developed on the anterior surface of the left leg. They had an appearance similar to those seen with varicose veins. They healed slowly, even though the patient was kept in a recumbent position. Latterly, some pigmentation of the skin over the legs has developed.

The subjective symptoms were (1) pain of a neuralgic character in the left side and less often in the back of the head. (2) Vertigo, occurring paroxysmally and sensations of syncope. (3) Occasional attacks of vomiting and continuous constipation. (4) Myasthenia during the cold weather. The objective symptoms were: (1) Acrocyanosis; (2) polycythæmia; (3) tachycardia, and (4) gigantic enlargement of the spleen.

In the absence of emphysema and heart disease, this state of chronic cyanosis was quite unaccountable. Moreover, the tremendous enlargement of the spleen and the polycythæmia were entirely new to me, and it was not until Osler brought the subject up for discussion at the meeting of the Association of American Physicians, this year, that I realized it to be one of the cases mentioned by the writers above mentioned.

After studying this case, it occurred to me that the very remarkable cyanosis of the extremities which a patient I had for a long time under observation in the City Hospital, who was suffering from spinal progressive muscular atrophy, the course of which was rather atypical, might be considered to be this symptom complex occurring with or engrafted upon the spinal cord disease. Examination of the blood showed hæmaglobin 100 +, red corpuscles 8,400,000, leucocytes normal. The spleen was not perceptibly enlarged, nor were any of the thoracic or abdominal viscera diseased. The pulse varied from 80 to 95. The heart was quite normal in size and in function. The urine was often high color, but it did not contain albumin. The patient was a Jew, forty-two years old, and a peddler by occupation. The muscular atrophy, which was of the Aran-Duchenne type, had begun four years before I saw him, and had progressed rather rapidly. The bluish-red color of the extremities was of about one year's duration. It was more intense in the lower than in the upper extremities. From the knees downward the discoloration intensified, the cyanosis of the feet being profound. There was but slight cyanosis of the face. I have seen a number of organic spinal cord disease with profound alteration of surface color of the extremities, but none like this. In a case of disseminated purulent meningomyelitis the patient had a remarkable scarlet color of one leg. In ancient cases of poliomyelitis coldness and blueness of the atrophied members is the rule. But in this case the cyanosis was profound like that seen in an advanced emphysematous patient after protracted physical effort or violent exercise. Unfortunately, the blood was examined only once, and the patient is no longer under observation.

The cyanosis is the striking feature of these cases. It has been confined to the extremities in all the cases save in two reported by Osler, in which the skin of the entire body was of a dusky hue, but the extremities were the parts profoundly affected. Cold intensified the cyanosis in both the cases reported herewith. The intensity of the color of the feet and legs does not diminish very materially when the patient is in bed. The surface temperature does not seem to be materially changed, nor is the function of the sweat glands noticeably altered. Pigmentation of the skin has been noted in most of the cases in which the symptoms had existed for a considerable time.

The enlargement of the spleen seems to be nearly a constant symptom. In seven of the nine cases in the literature it has been noted, and in the case of the young woman that I report, it was enormous.

In none of the cases reported was the spleen so much enlarged as in this one. In only one case, that of Vaquez, was the liver enlarged. This case is remarkable in other respects. There were paroxysmal hæmaturia and hyperalkalinity of the blood. The enlargement of the liver did not occur, apparently, until after the patient had been ill a long time. So far as the cases hitherto recognized justify the statement, we may say that the only viscus found diseased is the spleen.

The state of the blood has been very much the same in all the cases. The polycythæmia, which is the distinctive feature, is variable. In no case have the erythrocytes been below 8,000,000, while in one case (Cabot) they were 12,000,000. The average is about 9,000,000. The white corpuscules have been considerably increased in three cases, but in the majority there has been no leucocytosis. In one case reported by Osler the leucocytes were 30,000. The hæmoglobin percentage ranges from 110 to 165. Osler thinks that it is not possible to connect the polycythæmia in any way with the "moderate enlargement of the spleen," but in the case of the young girl that I report, it would seem very legitimate to connect the two, for the cyanosis did not appear until after the development of the enlargement of the spleen, and as Osler himself points out, cases of polycythæmia with enlargement of the spleen as the sole attributable cause have been reported. One thing would seem to me fairly certain, and that is the splenomegaly in my case could not have been the result of chronic, passive conjection. The subjective symptoms of the condition need not be mentioned further, as all that have been noted in any of the cases were enumerated above.

Dr. J. N. Hall of Denver has recently (*American Medicine*, June 27, 1903) published the notes of two cases, one of which was observed in Neusser's clinic. His own case was a Jewess, sixty-one years old, who presented intense cyanosis of the face, tongue, and upper extremities, the lower limbs and trunk being slightly affected. On the face were a number of tortuous veins, almost black in appearance. The pulse was 84, the arteries moderately atheromatous, the heart slightly enlarged. The lungs were slightly œdematous. The spleen could be satisfactorily outlined, but the writer thinks it was not enlarged. The urine was of low specific gravity and contained albumin and casts. The blood was very dark, and coagulated rapidly; erythrocytes, 9,049,000; leucocytes, 6,500; hæmaglobin, 170+.

That this is no a typical case need scarcely be said. The atheroma of the blood vessels, its manifestation in the kidneys and heart, the œdema of the lungs, and the dilated tortuous superficial blood vessels of the face account for the cyanosis. Polycythæmia in such conditions is not infrequent.

The second case was that of a woman, forty years old, who presented a reddish-blue hue of the face which somewhat resembled the cyanosis of advanced emphysema. It was not constant, but it became deeper upon eating and upon excitement. There was slight cyanosis of the hands. The spleen was very much enlarged. In this case also there were large, dark veins upon the face. The blood contained 9,935,000 red cells, 22,000 leucocytes, hæmaglobin 170, and was of such thick consistency that it would scarcely flow. This case is reported very briefly, but it would seem to conform very closely with the cases reported by Cabot, Osler, and myself.

What may prove to be a very important contribution to this subject is a case of hyperglobulism and tumor of the spleen reported by Rosengart of Frankfort-on-Main in the Mikulicz and Naunyn, *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, part 4, 1903, p. 495. The patient, a man forty-one years old, presented clinically, in addition to a large tumor of the spleen and moderate enlargement of the liver, a peculiar violet, reddish-yellow color of the skin, especially of ears, cheeks, nose, lips, and hands, constituting well-marked cyanosis. The tumor of the spleen had first been detected immediately after a severe attack of measles which the patient had when he was thirty-seven years old. He complained of pain in the stomach, vomiting after meals, severe attacks of vertigo, nervousness, weakness, emaciation, and dyspnœa, especially on slight exertion, such as talking. The pulse was full, from 96 to 104, the arteries elastic, the blood-pressure increased. The apex beat was not discernible, but the heart was enlarged, and a distinct systolic murmur, not closely confined, was to be heard. There was no trace of emphysema. The blood was of a dark cherry-red color, its consistence much increased. The specific gravity 1072; hæmaglobin, 190 to 200; red blood cells, about 10,000,000; white corpuscles, 12,000; the blood plaques diminished in number.

This writer, who is evidently not familiar with the English and American writers quoted above, mentions that, in 1883, Scharold (*Aerztliche Intelligensblatt*, 1883, No. 32) reported a case of acute miliary tuberculosis of the spleen which enlarged that organ to three times its normal size, and which was associated with profound cyanosis of the face and nosebleed. The case of Rendu and Widal (Société méd. des hôpitaux de Paris, June 2, 1899), in which there was tumor of the spleen, cyanosis, and hyperglobulism amounting to 6,200,000, is also mentioned.

In January of last year Türk showed, in the Gesellschaft für innere Medizin in Vienna (*Wiener medicinische Wochenschrift*, No. 5, 1902, p. 226), a case in which an enormous tumor of the spleen of ten years' standing was associated with intense cyanosis of the face, lips, ears, and hands. The blood showed 9,080,000 erythrocytes, 23,100 leucocytes. hemaglobin 180 per cent.; specific gravity, 1070. A peculiarity of the blood was the presence of megalo-, micro-, and poikilocytes, and in many of the cells polychromatophilia. Whether the case is the same one referred to by Hall, I am unable to say. Hall saw his second case with Türk in Neusser's clinic.

Other cases in which spleen tumor has been found in connection with cyanosis of the extremities have been recorded by Collet and Gallavardin (*Arch. de méd. exp. et d'Anat. path.*, March, 1901, No. 2). In this case the erythrocytes were not counted, but the general physical features of the blood were similar to the other cases.

Cominotti (*Wiener klinische Wochenschrift*, 1900, No. 39) has also reported a case of hyperglobulism and splenomegaly that may be mentioned, particularly as there was no cyanosis.

These cases are suggestive, although they may not be fitted in the same category as the cases reported by Osler, Cabot, and myself. From a consideration of them and the other cases mentioned above, I am inclined to believe that alteration of the spleen will later be shown to be an essential accompaniment of this symptom complex.

Of the thirten cases reported, seven were in males and six in females. All except the case of the girl which I report were in the middle period of life—that is, if Hall's first case is not included. So far the symptom-complex is not attributable to any cause. Of the cases reported, three have died, one in collapse, one in coma from cerebral hemorrhage, and

one in coma of unknown dependency. The autopsies of these cases did not contribute to an interpretation of the symptoms.

32 West Thirty-eighth Street.

## THE PROGNOSIS AND TREATMENT OF CHRONIC DEAFNESS.*

By PHILIP D. KERRISON, M.D.,
NEW YORK.

Instructor in otology in the University Bellevue Medical College; assistant aural surgeon to the Manhattan Eye and Ear Hospital.

The title of this paper is obviously unscientific, for deafness is a symptom, and not a disease; and the disease must be determined before a prognosis can be thought of.

Chronic deafness, however, is a term which so frequently finds its way into medical literature and discussion that it has come to convey a fairly definite meaning, viz., an impairment of hearing which has been more or less gradual in its development, and has persisted for a considerable period of time. It is used, therefore, advisedly as best expressing what I wish to convey.

Is chronic deafness curable? Can anything be done to relieve deafness that has persisted one, two, five, or ten years? So often is this question asked by physicians as well as laymen, that one is forced to conclude that a rather general impression exists that deafness is not amenable to treatment. Once deaf, always deaf, seems to be the popular dictum. I have thought, therefore, that a brief statement of what may be expected of rational treatment in this direction might not be without interest.

There are two general classes, to one of which every case of chronic deafness must be referred, viz.: (1) *Labyrinthine deafness* or deafness due to disease of the labyrinth, or auditory nerve. (2) *Tympanic deafness*, or deafness due to disease in some portion of the conducting apparatus, *i.e.* external meatus, drum membrane, ossicles, or Eustachian tubes. In the class of cases first mentioned, *i.e.* when the lesion is confined to the labyrinth or auditory nerves, the conducting apparatus may be in no way at fault. The sound-waves may be taken up by the drum-membrane and ossicular chain, and properly conveyed to the inner ear; but here, owing to the labyrinthine lesion, the sonorous impressions are not conveyed to the auditory brain centers, and are not appreciated as sound.

Deafness due primarily to labyrinthine disease, however, is comparatively rare, which is the more fortunate, since the prognosis is in the majority of cases doubtful, and often positively bad. Labyrinthine deafness we shall not consider in this paper.

At least 95 per cent. of all cases of deafness are due primarily to tympanic disease, or to disease originating in some portion of the conducting apparatus. In the later stages the labyrinth may also become involved, but in such cases the labyrinthine disorder is secondary to the tympanic disease, and is usually checked or relieved by treatment directed against the tympanic lesion.

The large majority of cases of chronic deafness, then, are of tympanic origin, and may be considered under the following heads:

1. *Chronic tubal catarrh*, in which there is marked narrowing, or actual stenosis, of the Eustachian tubes.

2. *Chronic hypertrophic catarrh* of the middle ear, in which the tympanic mucosa, and all the joint structures of the ossicular chain may be involved.

3. *Suppurative processes within* the middle ear, resulting in partial or complete destruction of the drum-membrane, malleus, and incus.

4. *Chronic hyperplastic otitis*, also spoken of as "dry catarrh," or sclerosis of the middle ear.

*Chronic tubal catarrh*, with stenosis or marked narrowing of the Eustachian tubes, is probably the commonest condition associated with deafness. In the early stages of these cases, the deafness is purely a mechanical one, and is due to an interference with the movements of the drum-membrane and ossicles, though these structures may be in no way diseased. The loss of ossicular mobility is dependent upon morbid changes originating not within the tympanic cavity, but in the Eustachian tube. The exact changes within the tube may vary in different cases from a simple chronic congestion of its mucous lining to a structural diminution of its lumen, or actual stenosis. But whether the obstruction be due to venous congestion, or to an actual deposition of new connective tissue, the result is mechanically the same, viz., partial or complete occlusion of the tube.

Naturally, pathological conditions within the tube may exist for a considerable period of time without producing symptoms referable to the ear, but as soon as the caliber of the tube is reduced to the point where the passage of air to the tympanum is prevented, there can be but one invariable sequence of results, viz., the air within the tympanic cavity is exhausted, and the drum membrane is forced inward by atmospheric pressure from without, carrying with it the malleus handle, and crowding the ossicles together. Under these conditions it is obvious that neither the drum-membrane nor the ossicles can vibrate as well as under normal conditions.

In this simplest form of chronic deafness, the indications for treatment are happily logical and clear, viz., measures looking to the restoration of the Eustachian tube to its normal caliber.

The plan of treatment should include recognition and correction of existing diathetic conditions, *e.g.* gout, rheumatism, etc., and of abnormal conditions within the upper-air passages, *i.e.* nasal cavities, nasopharynx, and pharynx. But the essential point of attack is the Eustachian tube. Inflation per catheter not only tends to open and restore the tube to its normal condition, but is invaluable as a diagnostic measure. By use of the otoscope, the practiced ear can, during inflation, obtain very definite data as to the exact condition of the tube, and further measures of treatment indicated.

In some cases systematic inflation at regular intervals may be all that is necessary to bring about rapid improvement and cure. In others the use of stimulating vapors, *e.g.* menthol, ether, camphor, iodine, etc., projected per catheter into the tube, may prove beneficial. The immediate result of this measure may be a vascular reaction, rather tending to a temporary increase of symptoms which later subside as the parts take on a more healthy tone. Still other cases of tubal narrowing, or stenosis, will yield to nothing short of mechanical dilatation. This may be accomplished by means of the ordinary cotton-wound wire bougie, by graduated whalebone or celluloid bougies, or by the electrolytic method devised by Dr. A. B. Duel of this city. In the experience of the writer the latter has been by far the most efficacious means of overcoming a stricture within the Eustachian tube.

But in practiced hands the method of attack does not greatly matter, *provided the end in view be attained*, viz., the restoration of the tube to

*Read before the Alumni Association of Gouverneur Hospital.

its normal patency. Where this is accomplished the effect upon the auditory function is almost invariably a marked improvement in hearing.

*Deafness Depending upon Chronic Hypertrophic Catarrh of the Middle Ear.*—This condition is invariably associated with pathological changes within the Eustachian tubes, which are usually abnormally narrow. Within the middle-ear cavity there is a chronic productive inflammation involving the mucous membrane covering the tympanic walls, the ossicles, and the ligaments holding the ossicles together. In the early stages the condition is probably one of moderate venous congestion, chronic in character, but subject to periods of amelioration. Later, as is always the case with prolonged congestion and low forms of inflammation, there is a deposition of new connective tissue. The hypertrophy may involve not only the mucosa of the tympanic walls and inner surface of the drum membrane, but all the joint structures of the ossicular chain. The process is gradual, and years may elapse before its presence is made known to the patient by an appreciable impairment of hearing .

In these cases the deafness is not difficult to explain, for we have to consider two distinct lesions, either of which alone might cause deafness:

1. Owing to the morbid changes within the Eustachian tubes, these air passages are usually distinctly narrowed, or may be practically closed, with the result that the normal passage of air to the tympanic cavity is proportionately interfered with. As invariably follows exhaustion of the air within the tympanum, the drum membrane is forced inward by atmospheric pressure from without, crowding the ossicles together and holding them in a state of partial fixation. This condition alone would cause impairment of hearing.

2. But in addition to the above, we have the tympanic lesion proper to contend with. Whether the condition here is one of chronic venous congestion, or has progressed to the stage of actual hypertrophy, the mechanical effect is the same, viz., impaired mobility of the ossicular joints; and fixation of the ossicles means impairment of hearing. The deafness, then, is the logical sequence of the disease, and a knowledge of the underlying lesions suggests the rational line of treatment.

Clearly the indications are, first, to restore the Eustachian tube to its normal tone and caliber, thus releasing the drum membrane from its position of retraction; and, second, to restore the tympanic mucous membrane as nearly as possible to a healthy condition.

For the first indication the measures suggested under the treatment of tubal catarrh may be employed, *e.g.* inflation per catheter at regular intervals; application of astringent solutions to the nasopharynx and pharyngeal mouth of the tube; medication of the tubal mucosa by stimulating vapors; these failing, mechanical dilatation by graduated bougies, or by electrolysis. The main point is the recognition of a constriction, if it exist, and the adoption of adequate measures for its correction.

With the reëstablishment of equilibrium between the atmospheric pressure on both sides of the drum membrane, there is almost invariably an increase in hearing power. The subsequent improvement is usually slow, and must depend upon the gradual return of the intratympanic structures to their normal condition. Nothing so tends to hasten this result as the automatic ventilation of the tympanic cavities through the Eustachian tubes. To this end the patency of the tube should be maintained by occasional gentle inflation. At longer intervals pneumatic massage of the membrana-tympani may be employed to exercise the ossicles and restore their mobility. The upper-air passages should be brought as nearly as possible into a healthy condition. This is most important in preventing recurrent attacks of acute tubal catarrh which react upon the ear. Drugs locally applied through the tubes have many advocates but very limited usefulness.

But no dogmatic rules can be laid down for this stage of the disease, which must vary with each individual case. This much, however, may be said as applying to all cases of this class, viz., that when a stricture or constriction of the Eustachian tube exists vigorous measures may be required, and should be employed for its correction. As soon, however, as the patency of the tube is reëstablished, our endeavor should be to assist nature to bring about a return to the normal, rather than to force this result by over-meddlesome intervention. A slower improvement, if permanent, may be of more value to the patient than the most brilliant result followed by a relapse.

*Deafness Due to Suppurative Processes within the Middle Ear.*—There is still a more or less general impression, among physicians as well as laymen, that a ruptured drum membrane means deafness. Fortunately this impression is not founded upon fact. On the contrary, fairly good hearing power is by no means inconsistent with practical destruction of the drum membrane.

Normally the drum membrane, malleus, and incus form a very important part of the perfect sound-conducting apparatus; but after their removal it is quite possible for the stapes, acting alone, to receive sonorous impressions from without and transmit them through the oval window to the labyrinth and end organs of the auditory nerve.

Accepting these statements as facts, we are prepared to consider those cases in which the impairment of hearing is the result of prolonged suppuration within the middle ear.

These sufferers constitute a large percentage of the patients applying to the ear clinics for treatment. The typical history is that of a chronic discharge from the ear beginning in childhood, and persisting for a period of years, or well into adult life. On examining these ears by reflected light, we always find more or less destruction of the drum membrane. The malleus and incus are also usually involved in the destructive process. The incus particularly is prone to undergo necrosis, and may be completely destroyed. The stapes, on the other hand, by some fortunate provision of nature, is very rarely involved in the necrotic process, and even after practical destruction of the two larger ossicles, is usually unharmed. This immunity is probably due to its comparatively protected position in the niche of the oval window, and to the fact that its blood supply is not interfered with by pressure during the progress of inflammatory processes originating within the tympanic vault.

But while the actual loss of substance varies in different cases, the drum-membrane, malleus, and incus have not infrequently lost all connection with the stapes, and have therefore ceased to play any part in the function of sound conduction. To the stapes, therefore, we owe whatever hearing power remains.

Naturally the hearing is usually somewhat impaired. But surprising as it may at first seem,

these patients, as a rule, suffer less seriously from deafness than those having any other form of tympanic disease. That is to say, the impairment of hearing is less marked, and the prognosis as to ultimate deafness is less grave.

Many of these patients apply for treatment, not on account of deafness, but for relief from the chronic purulent discharge, in which case the treatment does not come within the scope of this paper. There are other cases, however, in which the suppurative process undergoes spontaneous cure. The very loss of substance may create a passage favoring free drainage; necrotic portions of the ossicles and tympanic walls are thrown off in the form of minute sequestra; the exposed tympanic surfaces are covered in by a process of epidermization, and the discharge ceases. The patient may now seek relief for a very considerable loss of hearing power.

The treatment in these cases is surgical, and consists in the correction of any condition interfering with the mobility of the stapes. The stapes, for instance, may be buried beneath a mass of cicatricial tissue seriously interfering with its mobility. In such a case the logical treatment would be the division and removal of this tissue. When this is successfully accomplished, the liberation of the ossicle will be manifested by prompt and appreciable improvement of hearing. In other cases, constricting bands are found passing from the crura of the stapes to the walls of the oval niche; the stapedius muscle, being no longer opposed by the action of the tensor tympani, may interfere with the freedom of the stapes. Division of these structures will often result in marked improvement of unction.

These operations, when successful, often furnish the most brilliant immediate results. Unfortunately a part of the initial gain is almost invariably lost as the operation wound heals. The final net result, however, is often an appreciable improvement of hearing.

*Chronic Hyperplastic Otitis Media;* or Dry Catarrh of the Middle Ear; also called Sclerosis of the Middle Ear. The deafness occurring with this disease is the most discouraging that the otologist is called upon to treat.

In typical cases the morbid process seems to be that of a low form of subacute inflammation in which congestion at no time plays a prominent part. It is apparently a productive imflammation from the start, in which the newly formed connective tissue contracts, pressing upon the normal structures of the tympanic mucosa, which is converted into a dry, sclerotic membrane, closely adherent to the tympanic walls. The same changes occur in the mucous lining of the Eustachian tubes, and these passages are often abnormally wide. The drum membrane, therefore, is usually not retracted. Within the tympanum there is also a deposition of new connection tissue in the form of adhesive bands binding the ossicles together and to adjacent structures.

In addition to the above changes there are undoubtedly many cases in which a true osseous ankylosis exists. In such cases the chief lesion may be a hyperostosis in the vicinity of the oval window. Several post-mortem observations have been recorded by Politzer, Bezold, and others, in which a proliferation of new bone in the neighborhood of the stapes had resulted in a true osseous union between the foot-plate of the stapes and the margins of the oval window. Unfortunately we have no means of determining positively the reseence of such a lesion, which adds a further element of uncertainty to the prognosis.

Here, again, we have deafness due to impaired mobility of the ossicular chain, but in this disease the lesion is rather of the nature of a true ankylosis. The drum membrane may be normally placed and free, but the ossicles are held by constricting bands, which bind even the stapes to the walls of the ova niche and window.

The treatment, be it confessed, is less satisfactory than in any other form of tympanic deafness. In the initial stages much benefit may result from the use of stimulating vapors, *e.g.* iodine, ether, camphor, chloroform, etc., thrown into the middle-ear cavity through the Eustachian catheter. By this means the local blood supply is increased—a result favoring the restoration of the parts to their normal condition. Forcible inflation per catheter may be employed at long intervals to break down or prevent adhesions between the ossicles and adjacent structures. Occasional pneumatic massage of the drum membrane may be used to restore the mobility of the ossicular chain.

Such measures, however, are of value chiefly at the onset of the disease, and their usefulness becomes progressively less as the disease advances. Later on, when the deafness has become pronounced, but little can be expected of conservative treatment beyond retarding the progress of the disease, and possibly preventing a further impairment of function. Still later we arrive at a stage of the disease in which the drum membrane, malleus and incus, instead of aiding in the conduction of sound, act as a veritable barrier to the passage of sound waves to the inner ear. This condition palliative measures are powerless to relieve. The surgical treatment, once enthusiastically proclaimed both in this country and Europe, finds fewer advocates as the results are subjected to the crucial test of time. Nevertheless, there are certain cases for which, in the light of our present knowledge, we must either fold our hands, or look to surgery as offering the only possible means of improving the patient's hearing.

Briefly stated, the operation proposed in these cases consists of the removal under the most rigid aseptic precautions of the drum-membrane, malleus and incus, great care being observed to disarticulate the incus from the stapes without injuring the latter, or dislodging it from its position within the oval window. It is in effect an attempt to convert the condition to that described under the last class of cases, in which the stapes, acting alone, is permitted to take up sound waves from without and transmit them to the labyrinth. Personally, the the writer has never felt justified in strongly advocating this operation for the improvement of hearing; nor have the results of such cases as have come within his knowledge after being operated on by others seemed altogether favorable. Considering, however, the large number of suppurative cases in which good hearing power is retained after removal of the drum-membrane, malleus and incus, the operation under discussion seems rational enough.

Obviously in those cases in which a true bony union between the stapes and oval window exists, no improvement could possibly result from operative measures. In such cases, however, it is probable that the deafness would be extreme, and that the functional tests would give evidences of sufficient labyrinthine involvement to contraindicate the operation.

In properly selected cases, *i.e.* when serious labyrinthine disease can be excluded, the immediate result of the operation is probably almost always a decided improvement in hearing. The danger now lies in the tendency of adhesions to re-form between

the stapes and adjacent structures, and the difficulty of preventing this has led many to abandon the operation as involving too great uncertainty and risk. But in considering this, it must be remembered that in the later stages of this disease, the condition, so far as the hearing is concerned, is a desperate one.

What then should be our attitude toward this class of patients? In the opinion of the writer, it should be somewhat as follows: We should consider first the stage of the disease and the degree of deafness. In the early stages, when the impairment of hearing is slight, our efforts should be directed against any constitutional or diathetic disorders, and the local measures already described should be employed. But there is a later stage, in which the hearing is greatly impaired, though still sufficiently good to allow considerable enjoyment of life. Though unable to take part in general conversation, the patient may be able to converse without great difficulty with one person seated near him. The treatment outlined above may now be powerless to restore the hearing power, but may serve to prevent further loss. In such a case the aim should be to conserve to the patient his present hearing power. Careful functional tests should be made at stated intervals, and when it can be shown that no further impairment is taking place, the patient should be advised to be satisfied with what is still his. But when the deafness is marked, and in spite of all that we can do, becoming progressively worse, he should be told frankly that the prognosis is unfavorable and that surgical intervention offers his only chance of relief. The nature of the operation should be explained to him, and the chances of success and the chances of failure should be fully stated. The facts having been thus placed before him, the patient should be left to assume the responsibility of a decision.

Before leaving the subject a word should be said as to the four types of deafness here described: While the division of all cases of tympanic deafness into four classes may seem more or less dogmatic and arbitrary, this is necessary as a working hypothesis, without which a practical view of the subject would be impossible. With this statement it is well to admit at once that in any given case, one type may gradually merge into another. Thus a case of chronic tubal catarrh may develop later into one of chronic hypertrophic otitis; and more rarely a case of chronic hypertrophic otitis may become sclerotic in character. It is for the physician, by his careful physical examination and functional tests, to determine the lesion; or where two lesions exist, which is the more urgent.

The writer has made no attempt in this paper to discuss all the therapeutic measures at our disposal, nor the technique in applying them. Nor has it been possible in the time at his disposal to touch upon the diagnostic value and significance of the functional reactions which have such an important bearing upon the prognosis. His purpose has been solely to consider very briefly the commoner ear lesions causing deafness, and to outline the more rational lines of treatment therefor.

But to return to the original question—What can be done for the relief of chronic deafness? In considering this question, the writer is not a pessimist. He believes:

1. That there are certain cases of advanced catarrhal deafness—even among those in which no evidence of serious labyrinthine involvement can be found—which do not respond to treatment.

2. That in the large majority of cases the power of audition can be distinctly improved.

3. That in the early stages of catarrhal, or tympanic, deafness the majority of cases are susceptible of practical and complete cure.

4. That in advanced stages of catarrhal deafness rational treatment often results in an improvement, which adds greatly to the patient's enjoyment of life, though the normal hearing power may never be regained.

5. That where but slight improvement of hearing is accomplished, the result of treatment is often of value to the patient in arresting a process which might otherwise lead to very marked or total deafness.

## INTERNAL ADMINISTRATION OF ICHTHYOL IN PULMONARY AFFECTIONS.

By MAURICE ROSENBERG, M.D.,
NEW YORK.
ATTENDING PHYSICIAN, BETH ISRAEL HOSPITAL DISPENSARY, CHILDREN'S SERVICE.

In the treatment of pulmonary affections we often come in contact with cases which are on the border line of pulmonary tuberculosis; and again, cases in which the pulmonary lesions are not much advanced, but tubercle bacilli have already made their appearance in the sputum. These are the patients whom we like to send away to a suitable climate, and who, when away, do very nicely, and return, after varied periods, in good condition, and we call them cured. But we also have patients affected as stated above, who, owing to the fact that they have to earn their livelihood, are compelled to remain at home and do the best they can, and for whom the physician has to do what a suitable climate does for the better placed patients.

It has been customary to treat these patients with cod-liver oil, forced dieting, and guaiacol or creosote in some combination.

I have not had much success with these, and was forced to look for other remedies. I tried ichthyol on the first patient who presented himself, and it is with great satisfaction that I report the following cases:

Ichthyol is a natural product obtained by dry distillation from a bituminous mineral. It is soluble in water; it contains a large percentage of sulphur in a form which is at once soluble and readily assimilable. I have used ichthyol always mixed with water, never in capsules, having thus obtained better results, giving it before meals. There has been no gastric disturbances in any case except a slight diarrhœa, which is easily relieved, or some eructation, which stops as the patient becomes accustomed to the drug. It has in many cases proved for me that it will increase assimilation; improve nutrition, check waste, thereby increasing bodily weight and act as a germicide against the tubercle bacillus.

Case I.—M. K., male, age twenty-six years, collector; family history good. Has had a cough for about six months, his weight in that time being reduced from 160 to 140 pounds. Appetite poor; bowels regular; afternoon temperature from 100° to 101°. Throat clear, a few râles at the left apex; sputum negative, after two examinations. Suitable remedies reduced the frequency of the coughing attacks; but the temperature continued and the râles persisted. I then prescribed ichthyol grs. v, three times daily in watery solutions, to be taken before meals. I also ordered him to include plenty of milk, eggs, and meat in his diet, and to sleep in a room with the windows entirely open. In one week his appetite had improved, but his cough persisted.

I ordered the ichthyol increased to three drops each day until he was taking 30 drops three times daily. At the end of six weeks he weighed 167

pounds, showing an increase of 27 pounds. The coughing had entirely stopped, the râles were gone. This case was similar to others which I had previously treated under the same hygienic routine with cod-liver oil, and creosote or guaiacol, and had never obtained such results in so short al time. Ichthyol had increased the man's appetite until he was taking two quarts of milk, and also three meals, which included six eggs, daily. There was at no time any gastric disturbance, beyond a little diarrhœa, which I relieved by adding some bismuth to his milk. It is now two years since treatment was discontinued, His weight has remained stationary. Has not been coughing since. He had been under treatment but three months. It is thus clearly shown that ichthyol had increased the assimilation, whereby his nutrition had been improved, his body weight more than restored, thereby strengthening the pulmonary frontier against tuberculosis, toward which this man was certainly bound.

Case II.—Mrs. Mary S., age forty years, married; mother of seven children; menses regular. Had dry pleurisy several years ago. Was in good health afterward, until she had an attack of catarrhal jaundice three years ago, from which she entirely recovered after losing 30 pounds in weight. Soon after she began to cough. Had severe pain over the region where the pleurisy had been on the right side, and the patient looked as if there had been cancer obstructing her gall-bladder instead of catarrhal jaundice. There were râles over the right apex and signs of the old pleurisy at the base. On examination by the Health Department, her sputum showed "few" tubercle bacilli. Appetite was poor, bowels regular.

I put her on ichthyol 5 gr. three times a day. At the same time, ordered her bowels flushed twice daily. The ichthyol was pushed till she took 30 gr. three times daily. The hygienic habits of the patient were looked after. Her condition showed signs of improvement at once. Cough was moderated. The amount of sputum expectorated lessened, and its character changed from lumpy to more fluid. Her weight gradually increased until, after three months' treatment, her 30 pounds were regained. At this time her cough had entirely ceased. Sputum was reported by the Health Department to be negative, and after three years' watching, I have added this case to my list of cured cases of tuberculosis.

In this case we can see how the economy has been strengthened to withstand the warfare of tubercle bacilli even to their extermination.

Case III.—Max J., age thirty-nine years, tailor; never sick. His father's brother had died of tuberculosis. The patient is 5 feet 8 inches in height. Weight 135 pounds. Is much emaciated. Large bony framework with winged scapulæ. He has applied for life insurance, which was refused on the ground that he was too light for his height. He was given ichthyol, and in two weeks gained 10 pounds; in two months 26 pounds. The ichthyol was then withdrawn. He has retained his weight, 161 pounds, and has obtained his policy. I attribute this phenomenal increase in weight simply and solely to the increased appetite produced by the ichthyol without deranging the digestion.

Case IV.—Mrs. Fannie B., aged twenty-five years; mother of two children, eighteen and three months respectively. The mother had died of pulmonary tuberculosis. The patient had always been well until two months after her last confinement, when she contracted influenza from which she recovered, but her cough persisted. She looked emaciated Her cough was hacking; there was an afternoon temperature of 101° to 102°. The sputum showed a moderate number of tubercle bacilli.

For two weeks cod-liver oil and guaiacol carbonate were given, nursing the infant was forbidden and the general hygiene looked after, but no improvement was noticed. The sputum became blood-streaked. The cod-liver oil and guaiacol carbonate were then ordered stopped, and instead she was given ichthyol, beginning with 5 gr., gradually increasing. There were immediate signs of marked and rapid improvement.

The sputum was at once changed in character and amount. Cough entirely ceased within one month, at which time her weight had increased 15 pounds. The number of bacilli in her sputum after one month's treatment was reported by the Health Department as few. She made a gradual recovery. After nine months there were no bacilli to be found upon repeated examination. All medication was then stopped, and although I have kept this woman under observation for over two years there has been no return of either cough or tubercle bacilli in the sputum. Although I do not put this remedy before the profession as a specific, I am positive that much good may be derived from the use of ichthyol, together with judicious hygiene and a sufficient dietary.

141 Broome Street.

## AN EXTREME CASE OF BRADYCARDIA.

By L. E. NORFLEET, M.D.,
Tarboro, N. C.

The subject of this paper, Mr. O. W., is a man sixty-nine years of age and of good family history. Nervous temperament, never used alcohol except medicinally. Has smoked or chewed tobacco since his boyhood, but at irregular intervals; has had to give it up on account of it making him so nervous that he could not attend to his work of a general insurance agent. General health was exceptionally good up to fifteen years ago, when he had an attack of typhoid fever, since which time he has suffered more or less from gaseous dyspepsia, which is hard to control on account of his being a very imprudent eater and having very poor teeth. Kidneys normal, heart normal, lung slightly emphysematous, arteries soft, no atheroma, stomach moderately dilated, bowels subject to attacks of diarrhœa.

For the last year he has noticed that his pulse was hardly ever over 45 and intermitted, but he paid no special attention to it, laying it to his dyspepsia. Last May he attended a Confederate reunion and became greatly excited at meeting his old comrades, made several speeches and attempted to give the "rebel yell," when he suddenly broke down and fainted. He was carried to a nearby doctor's office, who examined him, found his heart normal, prescribed a dose of ammonia and sent him home. After this Mr. W. found that any overexertion or excitement made him very uncomfortable about his heart, and to several of his friends he said he felt sure he was going to die suddenly, and his wife tells me he was often afraid to go to sleep on account of his irregular heart action.

Some weeks after this attack I was called in to treat him for indigestion, and without any special examination, I gave him a simple stomachic, which afforded relief for the time being. I will state here that I am his family physician and knew that his cardiac valves, etc., were normal. Mr. W. at this time stopped smoking and also ceased drinking the so-called "coca cola" soda-fountain drink, which heretofore, he thought, had bolstered up his heart action, and of which he said he took three or four glasses a day.

Early on July 24 I was sent for in haste, and was told on my arrival that Mr. W. had fainted. He was rational but very depressed, and told me that he felt as if he were dying. On examining his pulse I found it only 30 per minute, so soft and flowing that I could hardly count it, and intermitting badly. I at once gave him tincture of belladonna 12 drops, and tincture of strophanthus 3 drops, in a teaspoonful of brandy, to be repeated every four hours by myself. Returning at the end of four hours, I found a slight hardening and quickening of my patient's pulse, and diminished the next dose, and so on until 8 P.M. of the 25th, when his pulse had reached 65 and was almost free from intermissions. I reduced the dosage of belladonna to 5 drops and of strophanthus to 1 drop. At this time, a trained nurse arriving, I put her in charge of the case, giving her instructions not to awaken Mr. W. unless his pulse failed, and if it were necessary to continue the drops, to decrease the amount. At 3 A.M. of the 26th I was telephoned for, and when I reached my patient, who lives just across the street, the nurse told me that Mr. W. had slept quietly all night until a few minutes before three o'clock, when he suddenly had a convulsion, and after that his pulse had entirely disappeared. I now took his pulse and found it strong enough to satisfy any one, but beating in a most peculiar manner. As near as I can describe it, during the first ten seconds it would beat five times, then as suddenly, as if my patient had died, it would stop and for twenty seconds there would be not a single pulsation, then there would be three or four beats scattered about in the last thirty seconds. The heart beats corresponded to the pulse exactly. While I was examining Mr. W. he had a convulsion, and continued to have them at intervals of a few minutes for the next twenty-four hours. These also deserve further notice. The muscular spasm seemed to involve his head and neck alone, and only with the most severe ones did he have even a tremor of the arms. The attack would always begin with a rapid rotation of the eyes, then they would be turned up as if in prayer, this, in turn, followed by a looking downward—giving the face a ludicrous frown as if trying to frighten a child—which was followed by a sudden snap of the head to the left shoulder and a cessation of all spasm for the time. This cycle of changes, timed by the watch, took up from one-third to three-quarters of a minute. During the attacks the pulse ceased and the heart could not be felt or heard to beat. The respirations were hurried and puffing, sometimes almost whistling from the lips being held rigid. After the attack was over the heart beat more rapidly, and for a few seconds respiration seemed to cease altogether.

While the paroxysms were at their worst, the temporal artery could not be felt to pulsate at all. The face was pale but not livid and never congested. Mr. W. now began to vomit, and soon this vomit showed blood acted on by the gastric juice. He denied any pain or nausea, but still every few minutes would emit a mouthful of this black stuff. Owing to this vomit, I had to try hypodermic medication, and so gave him two doses of atropine sulphate, gr. $\frac{1}{150}$, with only an aggravation of all the symptoms. During the day he steadily grew weaker, and often expressed wonder at his living so long, as with each spasm he said he sank away from earth and felt sure that each one meant death. He claimed, and I think truly, to be unconscious during the attacks. The fingers and toes now shrank and became blue and I warned the family to expect the worst. Leaving him at 10 P.M., I ordered no medicine to be given but liquid nourishment in case the vomiting should cease.

Early on the morning of the 27th, I called to see my patient, expecting to find him dead, but instead found him resting quietly, not having vomited since midnight; the pulse was 16, while the paroxysms were less frequent and less severe. Medicines were ordered as before, but in smaller doses, and for the next twenty-four hours his condition remained about the same. I then ordered an entire change of medication, starting out with a hypodermic of morphine gr. $\frac{1}{4}$, and ordered nitroglycerin gr. $\frac{1}{150}$ and caffeine gr. $\frac{1}{2}$ every three hours. Three hours later there was a most noticeable change in the man's condition. The pulse was 20 to 24, with very slight intermissions, character much better; the paroxysms were less severe, only one or two occurring in the three-hour periods. The patient now asked for food. From now on the improvement was steady, though slow. The medicine was continued in same amounts, but at longer intervals. At the end of a week the pulse reached 74, where it has since stayed. The convulsions disappeared, but any worry or excitement would bring on one and will do so even now.

Mr. W., however, as he improved, changed from a calm anticipation of death, while at his worst, to a hysterical fear that any movement as to sitting up would cause his death by heart failure, and I had great trouble in even making him sit up in bed.

He is now up and about, with a pulse of 74, regular and good. He is taking nitroglycerin gr. $\frac{1}{75}$, caffeine gr. $\frac{1}{2}$ every six hours, and expresses himself as feeling better than at any time in a year, except for waking up at night with sinking sensations that are very annoying to him. I shall keep him on the above medicines for several months yet.

In looking over my notes of his case, I am struck with the following points in Mr. W.'s illness: (1) That any one should live and remain cool and conscious on an intermitting pulse of 8 or 9 per minute, and this for twenty-four hours. (2) That the drugs suggested by the textbooks—alcohol, strophanthus, and belladonna—not only did no good, but, in my opinion, were really injurious. Also that the last mentioned, though given in full doses, failed to redden the face, dilate the pupils, or dry the throat. Mr. W. told me that he had known for the last year that even small doses of alcohol were bad for him, an opinion that both the nurse and myself verified later on, for even the small amount of alcohol used to preserve a popular preparation of peptones would invariably increase the convulsive seizures and make the heart action more irregular. (3) The exact localization of the convulsive seizures to the head and neck, and the general pallor of Mr. W.'s face, as well as the failure of the cranial arteries to show any pulsation, made me regard both these seizures and the irregular heart action as being a species of epilepsy, due to anæmia of the brain centers, and it was with an idea of increasing the cerebral blood supply that I began the use of the morphine and nitroglycerin. And I must say that small doses of morphine, given two or three times during the day of the 28th, not only quieted a very restless condition that he had developed, but also gave his face a healthy color that had been absent before.

Mr. W. called me up a night or so ago, and I found he had a very bad dream, and woke up to find his pulse so fast as to alarm him greatly. I found it 85 to 90 and perfectly regular.

---

**A Big Boy.**—A case was reported in a French paper some time ago of a boy three years old who weighed 35 kilos about (77 pounds) and was 125 cm. (about 3 feet 9 inches) in height. There were two other children in the family, both girls and above the average size.

**The Surgical Treatment of Trachoma.**—J. Whitefield Smith says the surgical treatment that seeks to remove the developed granules has the following objects: First, to shorten the duration of the disease; second, to limit the amount or degree of hypertrophy; third, to lessen the inflammation and purulent secretion; fourth, to lessen the dangers of inflammatory complications of the eyeball, and sequelæ. The advantages of the author's forceps in the surgical treatment of trachoma are: The granulations are punctured at their crests and their contents evacuated without much traumatism to the conjunctiva. The incisions are uniform and practically of an even depth, so that the conjunctiva settles back against its basement membrane, producing a reasonably smooth and even surface. The tissue mainly involved in the operation is the developed granules; the intervening conjunctiva is not greatly implicated. By piercing the crests of the developed granules and evacuating them by gentle pressure, the inflammatory reaction is not very marked. In simply piercing the granules not much of the surface of the conjunctiva is destroyed, and this compensates, to a certain extent, the subsequent contraction in the disease-process. —*Illinois Medical Journal.*

**The Abuse of Flat-foot Supports.**—Wisner R. Townsend protests against the too common habit of treating flat-foot by various forms of support without consulting a surgeon. Errors in diagnosis are easily made, and ostitis of tarsus or ankle, metatarsalgia, neuralgia, or an inflammatory concretion of the parts about the inner side of the foot have been mistaken for flat-foot. In one case a sarcoma of the sole of the foot was treated for some time by braces. Moreover, when flat-foot exists, it does not necessarily follow that a support must be applied, for there are contraindications known to the profession, such as extreme spasm, extreme deformity, or inflammatory conditions. Another damage resulting from the indiscriminate use of supports, is that many cases, mild in type and easily cured by medical men, are allowed to grow worse, and the patient may become so seriously crippled that operation may be needed, or the case be incurable. The supports may not fit, may not support at all, and may increase, or even produce, deformity. Supports bought by the patient who is his own surgeon cannot be suitable when the principles of the disease are not understood.—*American Journal of Orthopedic Surgery.*

**The Reflexes in Nephritis.**—A. Lion publishes some observations on the behavior of the tendon reflexes, particularly the knee-jerks, in acute and chronic inflammations of the kidney. Many observers have already noted increased reflex irritability in various diseases, of non-nervous nature; *e. g.* Sternberg, who, in a series of one thousand cases, found that in more than one-half the cases having moderate fever due to various causes the reflexes were slightly but distinctly increased. This change was most noticeable in the early, even prodromal, stages, while with high temperatures or moderate fever of long duration the reflexes were entirely absent. The author's observations on nephritis lead him to conclude that in the great majority of cases the reflexes, and notably the knee-jerks, are exaggerated. The cause of this is assumed to be the uræmic poison which, circulating through the blood, throws the reflex system into a state of abnormal irritability. This is in accordance with v. Leube's view that nearly all the symptoms of nephritis are dependent on uræmic toxæmia. It is therefore in the chronic parenchymatous and severe acute forms of the disease that the greatest increase in the reflexes is to be expected and is found, and the author's clinical experience confirmed the theoretical conclusion that rapidly increasing knee-jerks were of grave import and portended uræmic seizures. In a very few cases with excessive œdema the sign was not present, probably owing to mechanical causes, but, as a general rule, an increase in the knee-jerks may be assumed to accompany renal lesions of severe grade, while a subsequent reduction in their activity means a change to a more favorable chronic form of the disease.—*Zeitschrift für klinische Medicin.*

**The Genesis of Epilepsy.**—Louise G. Robinovitch presents the following conclusions from her researches: A clinical study of the genesis of epilepsy shows that this convulsive disease is intimately connected with ancestral alcoholism. When closely traced to its origin, epilepsy appears to have its source, in great part, in epileptiform convulsions of alcoholic nature in the antecedents. When alcoholism in the father or mother, or in both, is absent, it is often found that alcoholism existed among the grandparents; and when the history is not sufficiently clear to incriminate any of the direct ancestry, the morbid predisposition is often indicated by the existence of alcoholism in the direct collateral family. Epilepsy may be transmitted from an epileptic parent directly to the offspring. Epilepsy may be transmitted through a generation free from the manifestations of the disease; the hereditary nature of the malady is then generally proven by the discovery of the existence of epilepsy in the direct collateral family of the preceding generation. Insanity, neuroses, psychoses, and criminality are often causes of epilepsy in the offspring. Acute contagious and infectious diseases occurring during pregnancy may cause epilepsy in the child; but it is a question whether these are to be accepted as the sole factors in the causation of the disease, for predisposing causes should be looked for. The chronic organic diseases cannot be accepted as the sole responsible factors in the causation of epilepsy. Syphilis, like other diseases, cannot be accepted as a specific factor in the causation of epilepsy. Microscopical cerebral pathology shows that an intimate relation exists between the morbid changes found in alcoholism and those found in epilepsy. This fact is logical because alcohol stands, clinically, as the main cause of epilepsy. Alcohol taken in excess in the form of wines, etc., does not cause true epileptic attacks; epileptiform convulsions are the rule in such cases; but the offspring of such subjects suffer from true epilepsy. Excessive use of absinthe causes true epileptic convulsions, and in such cases the offspring inherit epilepsy in the same manner as the offspring of the ordinary subjects of alcoholism. The birth rate is low and the death rate is high in the alcoholic family; the death rate is particularly high during infancy, the cause of death during this period generally being meningitis with convulsions. Of 140 cases of epilepsy considered, there was direct parental alcoholic heredity in 90, making a percentage of 64 plus. Considering the causes of epilepsy, it is evident that the prophylaxis is the most important agent for checking the growth of the disease.—*Journal of Mental Pathology.*

**The Ill Health of the Poet Whittier.**—George M. Gould, by means of extracts from Whittier's own letters, as well as from biographies and the testimony of friends, gives a description of the weakness, neuralgic headaches, and other pains which accompanied the poet through life. His headaches attended every mental exertion. He could not write or read continuously for half an hour, in middle or later life, without severe pain in the head. This debarred him from lectures, receptions, and public dinners unless an opportunity was given him to retire without notice and without causing a disturbance. He was supposed to be suffering from heart disease, but the author considers this and all the other symptoms to have been due to eye-strain. Compound hyperopic astigmatism complicated later by presbyopia was undoubtedly his trouble. With completed presbyopia, the reflexes ceased, and barring the infirmities of old age, there was freedom from the wretchedness of fifty years' standing. Had his life been cast among ours of to-day, he could have found instant and permanent cure of his now well-understood "nervous headaches." Every good American oculist of a few years' experience has had thousands of such patients. But there are still among us other thousands unnecessarily suffering precisely as did this most noble, pure, and lovable man.—*The Cleveland Medical Journal.*

## HEADACHES; DIAGNOSIS AND TREATMENT.

IN the *Sammlung klinischer Vorträge* (No. 361) Siegmund Auerbach says headaches are to be known as "functional" only after careful exclusion of possible organic disease. First one excludes brain tumor; then arteriosclerosis, brain syphilis, and periostitis luetica; pachymeningitis hemorrhagica (in which, at first, violent headache alone may be present); refraction and other ocular troubles; nasal and aural disease, and dental caries. Nephritis, diabetes, and all anæmias; also gastric diseases, and constipation must be considered. Of residual "functional" headaches, we know (1) neuralgias; (2) neurasthenic and exhaustion; (3) "hysterical" (better, suggested); (4) migraine; and (5) nodule, or plaque, headaches. Of all "headaches" Edinger estimates (4) and (5) as 40 per cent. each, while Auerbach rates them as ¼ to ½ and ½ to ½ respectively. Regarding the seats of irritation, Möbius has divided irritations of the dural nerves into mechanical and chemical; the former comprising the effects of increased intracranial pressure, the latter the various toxæmic irritations.

In diagnosis we first separate *supraorbital neuralgia*; never *in*, but always *on*, the head, unilateral (but almost always called "headache") and always associated with pain on pressure over the affected nerve (with none over the opposite). In alcoholics such a neuralgia (here a neuritis) of long standing is often the only sign of an intoxication, and speedily disappears upon abstinence. *Neurasthenic "headache"* is not a pain but a *pressure sensation*, though on violent overexertion real pain (exhaustion headache) may occur, as in the healthy. The complaint is often of a band drawn round the forehead; in more severe cases of a lead-cap feeling. *"Suggested" headaches* occur principally in morbidly suggestible women, usually arise from slight causes, and are generally associated with complaints of other bodily sensations, and, on examination, stigmata. The diagnosis of *migraine* is very easy in typical attacks. Especially important is heredity (father, mother, brothers or sisters), found by Möbius in 90 per cent., by Auerbach in nearly every case. Then the beginning in youth (if not indeed in childhood), the periodicity (definite attacks with free intervals), the prodromes (feeling of general exhaustion, chilliness, gaping, etc.), the usual fiery scotomata with jagged borders, the sensory aura (unilateral paræsthesias, usually on the opposite arm and often connected with transitory aphasia), form, with the unilaterality and the vomiting, a characteristic picture. Difficulties arise from the incompleteness of most attacks; often the prodromes are absent, generally the aura is lacking, sometimes the vomiting. Here the heredity and periodicity aid, especially in differentiating from nasal headache, which may be unilateral but which lacks, in addition, the vomiting. Finally, violent migraine-like attacks occur not rarely in tabes and paresis, which are always to be suspected when the attacks first appear in middle life.

*Nodule headaches* occur mostly in women of middle or advanced age, who were free from headache in youth. The duration is mostly years or decades. As a rule the pain is persistent, violent, in the whole head, but almost without exception originating in the occipital and cervical regions, frequently radiating down the back and toward the shoulders, not ceasing at night (frequently increasing on lying), rarely associated with nausea, never with vomiting. Bilaterality is practically invariable (only one case was unilateral). "Catching cold" bears a definite and decided relation to the disease, chillings of the surface, especially when moist, again and again bringing on exacerbations and relapses; and the patients were very sensitive to atmospheric disturbances, like rheumatics. Examination almost never reveals bodily defects, but careful palpation uniformly reveals millet-seed to bean-sized nodules in the subcutaneous tissue (and the fasciæ?) of the occiput and neck; at times also of the upper back, and frequently in the parietal region, where from their incapability of lateral displacement gives the impression that their seat is the periosteum. Also palpation along the linea semicircularis of the occiput from mastoid to mastoid reveals rather hard flattish or elevated deposits with a callous feel, occurring in the most various positions in the bellies of the muscles. All these are invariably very painful on even slight pressure. Sometimes they are impalpable, but the painful points displace themselves on displacing the muscles. Examination should be made with the muscles relaxed, and between the paroxysms, as thus the hyperalgesia does not lose its pathognomonic value, and, moreover, in migraine during the paroxysm painful spots are apt to be present.

Finally, the demonstration of the nodules is not always easy, unless one has gradually refined his sense of touch by practice. Diagnosis is usually easy, the foregoing characteristics forming a clear clinical picture. Occipital neuralgias are almost invariably unilateral, occur more in separate attacks, are never of such duration, and besides, permit of the demonstration of typical painful pressure points. Syphilitic bone pains present nocturnal exacerbations. Difficulties sometimes arise from the combination of this with other forms, as no form renders an individual immune against another. From migraine, besides the above characters, another interesting difference lies in the different reaction of the two forms toward remedies. While with migraine the persistent administration of bromides does much good, it does none in nodule headache; and massage, which cures the latter, has no effect on the former. Supposing proper treatment, the prognosis is, in general, quite favorable (much more so than in migraine), cases of even years' standing being curable. Of unfavorable, or at least dubious, prognosis are combinations with severe neurasthenia or anæmia. Here the general condition should be

treated first by feeding, quinine, arsenic, and iron, and such quietants as potassium bromide plus antipyrin, plus codeine phosphate with hot cataplasms locally several hours twice a day, and especially the careful avoidance of taking cold. In nodule headache during the cure elapses often occur, almost, always in connection with taking cold. The duration of treatment varies from three to four weeks to two to three months in the severest cases. The massage must be done either by the physician himself or by a masseur specially trained to detect the nodules, and the sittings should last from fifteen to twenty-five minutes, according to the sensitiveness of the patient and the size of the nodules. The first sitting is usually quite painful, and after it the pain is generally increased. During this painful period one should not stint analgesics, and to abbreviate it, Auerbach massages twice daily for the first two weeks. As a rule after eight to ten sittings massage is no longer painful, and the subsequent exacerbations are absent. Improvement generally becomes noticeable after three (with cases of longer standing it may be five or six) weeks. The massage should be begun by a powerfully stroking effleurage with the whole surfaces of the hands of both sides of the neck from the mastoids to the acromion; then the neck should be operated from the occiput, one side at a time, the operating hand being opposed by the simultaneous accompanying counterpressure of the other; each proceeding being done ten times. The muscles and skin from the occiput to the shoulder are then thoroughly kneaded (*pétrissage*), one side at a time, the aim being to raise each muscle between the fingers. Next, the whole occipital ridge, from mastoid to mastoid, should be massaged with the thumbs or closely approximated fingers, the operator endeavoring to reach each deposit, which should be treated not more than thirty seconds. Then the region from the sagittal suture to the ears is gone over six to eight times, and the individual nodules kneaded, and finally the frontalis, forehead and lateral facial regions are gone over similarly, ending with massage with the thumbs of the great vessels at the inner side of the sternomastoid.

## RESECTION OF THE LIVER.

THIS operation is subjected to an exhaustive critique by Dr. Willy Anschütz in Nos. 356–357 of the *Sammlung klinischer Vorträge*. Though experimental total exstirpation has never succeeded, Ponfick has removed three-fourths of the organ and the remainder has regenerated to four-fifths the normal size; and v. Meister has removed seven-eighths with a mortality of but 60 per cent., the remaining one-eighth hypertrophying to the original weight. Regeneration has likewise been observed after experimental necroses by injection of carbolic acid and alcohol. Coming now to the surgical question, the diagnosis of an hepatic tumor rests upon its situation in the hepatic region, its passage directly into the liver, and its following the respiratory movements, and the impossibility of holding it back during expiration.

With long-pedunculate or laterally displaceable tumors, only conjectures are possible. Where exact diagnosis has been attempted, the point of attachment was not certainly determined in 75 per cent., in 50 per cent. it was wrongly determined, and it was correctly made out in only 25 per cent. Before the preliminary exploratory incision one does as much as he can when he decides the really practical question whether a tumor is present which is probably amenable to surgical interference. Beyond this, he is fortunate if he can determine whether it is inflammatory, cystic, or solid. Exploratory punctures with the liver not in sight are to be warned against, as one can never be sure what he is puncturing. Sometimes only microscopical examination can determine the nature of the growth, and even this will not distinguish with certainty adenoma from primary carcinoma. With tuberous adenoma and multilocular echinococcus cyst resection is strongly indicated, but it is contraindicated in syphiloma, unless the tumor is long-pedunculate when the operation commends itself on account of its simplicity. Hardly any general prognosis is possible, since the statistics can scarcely be said to have much value, as they lump together so many quite dissimilar conditions. Still the comparative small mortality of 14 per cent. is surprising, and of this the operative technique seems responsible for but a small part (two deaths from hemorrhage, two from embolism, three or four from shock).

Turning now to the operation itself, while numerous incisions have been recommended, the real point is to begin with a small exploratory incision in the median line, or along the outer border of the rectus, until one has determined whether the tumor really belongs to the liver, and its nature. In almost all cases one is now first in a position to decide whether the case is a proper one for resection. This once settled in the affirmative, the incision is now to be recklessly enlarged, in any direction necessary, and the abdominal walls laid open, wide and gaping. In moving the liver great care must be taken not to tear it, this risk being greater than is usually supposed. Free exposure of the upper surface can be secured by a resection of the lowest ribs (the pleural sac not extending below the eighth rib), but Anschütz prefers Tricomi's procedure of division of the hepatic ligaments. The fear of a resulting wandering liver would, from what we know to-day of the causation of this condition, appear to be exaggerated. The fear of using the knife or scissors in cutting into the liver tissue is certainly an exaggerated one. Where the tumor is encapsulated it has been peeled out by the fingers or a blunt instrument. The principal interest in liver resections attaches to the methods for the control of hemorrhage. As regards the latter, different operations differ much; principally with the size of the liver wound, the condition of the surrounding tissue, and the nature of the growth, the second factor being the most important. The seat of the tumor, however, also influences greatly the prognosis, deep-seated tumors being more dangerous to remove; and the prognosis is also strongly influenced by the nature of the tumor (whether presenting a gradual transition to healthy tissue, and having large afferent blood vessels). Moreover, these are questions which can never be decided in advance, whence the advisability of great reserve in giving prognostications. There is nothing in the nature of the case which forbids the application of ligatures to the normal hepatic vessels, but usually the surrounding tissues are so modified that this

ideal method is impracticable. The same is true of the method of approximating two plane surfaces of a wedge-shaped excision by means of deep sutures, which has been done successfully where the liver tissue was sufficiently firm. Of all the methods available, the thermocautery is the favorite, and, used at a constant feeble red glow, it is certainly a preëminent styptic for the capillaries and small vessels, but with the larger it mostly fails. The application to the surface of a current of hot steam is inadvisable, though that of a current of heated air has been successfully employed, but while well-founded for bleeding from small vessels, it is dubious as regards certainty in the case of that from larger ones. Tamponning may be employed either temporarily or as a permanent method of compression. Concerning the advisability of permanent tamponning much difference of opinion exists. It finds its chief field in the case of cavities remaining after the removal of tumors. Finally, troublesome though hemorrhage may be at times, the fact remains that there is but one case on record in which it was the sole cause of death, and that one of the earliest ones. Moreover, while we might have submitted to hemorrhage as unavoidable, to-day we are justified in doing so only when we have exhausted the *prophylactic* means at our command. Of these the scope of clamping and elastic ligaturing is limited, and in large resections our chief dependence should be upon a series of intrahepatic ligatures whereby the liver can be tied off, section by section, so to speak. The handling of the wound should be by gauze drainage through the lowermost end of the wound to the exterior. While theoretically, infection of the peritoneum from the bile passages might be dreaded, in reality the danger is very slight, as normally the bile is sterile. The fixation of the liver by sutures to the wound is inadvisable, as the sutures are apt to tear out, and besides the respiratory movements of the organ are seriously interfered with.

## DRAINAGE AND SEWERAGE IN TROPICAL CLIMATES.

Discussing editorially a paper by J. W. Cornwall, the *Indian Medical Record* says that in tropical towns position mainly influences the choice of a system, those near water having fewer difficulties than inland towns, those on a slope than those in a flat region, etc. The municipalities while having little to spend, must nevertheless find means for collecting and disposing of (1) excreta, (2) sewage, (3) liquid waste from factories, (4) storm water, and (5) silt (mud, sand, and putrescible matter deposited). The system must dispose of house refuse and street sweepings, as decomposition sets in rapidly and winds disseminate them. Storm water constitutes an, as yet, unsolved engineering problem. The silt varies with the character of the house and street connections, of the soil and habits of the people. After low-caste passers by, crows, kites, dogs and stray cattle have eaten their fill, the residue consists of dust, vegetable refuse, rags, paper, crockery, tins, and often considerable fecal matter, the whole decomposing readily but burning only with fuel. Pits for excreta and rubbish together attached to houses, result in putrefaction instead of nitrification, and the soakage from them pollutes all neighboring surface wells, sometimes rendering them so brackish that they are abandoned. Few of the many dozens of privies suggested for native houses work sanitarily, while the most various public latrines are generally a terrible nuisance. The best are those where both buckets and contents can be removed together and cleaned elsewhere. Collection of excreta in public carts can hardly be conducted without grave nuisance, unless the dry earth system prevails, and disposal by burying or trenching is satisfactory and profitable only when suitable land is available near the town. The ideal ground is one large enough for trenching, not more than one foot deep at the outside being dug, into which not more than nine inches of night soil is poured. Trenching requires one acre for 4,000 persons, that space becoming filled in 315 days; but, the conditions being favorable, it is quite possible to rebegin trenching, crosswise. Burial in deep pits is never to be recommended. Burning night soil plus rubbish or fuel in incinerators, is successful on a small scale at some places, but it would hardly be practicable on a large scale and has little to recommend it.

The collection of sewage is performed in various ways. The open or closed impervious catchpit, the underground pervious sinkpit, the roadside channel excavated with no lining, the open-brick drain, the open V-shaped drain made of stone slabs, and the U-shaped cemented drain. The *open side drains* have nothing to recommend them, though the arguments adduced in favor of them are that: (1) They are open to view and all obstructions are readily seen and removed; (2) there can be no collection of foul gases; (3) they cost less to build and to maintain; (4) no traps, ventilators, etc., are required; and (5) rats are not harbored. Their disadvantages, however, are overwhelming: They occupy space on the roadway, need constant repair, road detritus blows into them, everyone throws in rubbish, it is rarely possible to obtain proper gradients, and it is impossible, even with the aid of flushing, to prevent the formation of black offensive slime on the sides. *Closed sewers*, on the other hand, though not entirely free from objection, have many advantages; but to be at their best, they must be connected directly with the houses, so that all drainage passes directly into them, and no opportunity is given for detritus to find an entrance. Probably in few places can the practice of discharging sewage untreated into the sea or watercourse be defended. Waste land is generally available somewhere near towns, and owing to the rate of evaporation and the frequent impossibility of carrying on any sort of cultivation without free irrigation, the obvious method is to irrigate land with the sewage and grow crops. Only in places where the rainfall is very heavy will this be impossible all the year round. These are the very places where it is easiest to allow the sewage to run into a watercourse, and where least harm is likely to result from doing so. There is no object in treating sewage by chemical methods before utilizing it; nor, as a rule, is there any particular advantage in subjecting it to the action of bacterial filters. Experience has shown that the land is perfectly well able to deal with crude sewage for ten years in succession without getting its pores blocked by deposit, provided that the supervision is intelligent.

## VARICELLA AND VARIOLA.

Dr. Spencer L. Dawes of Albany Medical College read a paper on the above subject before the Medical Society of the County of Albany, published in the *Albany Medical Annals*, October 12, 1902. The question which Dr. Dawes discussed was the duality, or what von Jürgensen calls the "universality" of varicella and variola. Most American medical men are staunch believers in the duality of the two diseases, while perhaps the majority of Europeans who have interested themselves in the matter agree with von Jürgensen.

The author first presents a brief résumé of the history, etiology, and course of varicella, together with arguments for and against the question in point, and then describes an epidemic of the affection which came under his direct notice.

As to the history of the disease, it was first described in 1550 by Vidus Vidius and Ingrassius of Naples, who called it "crystalli," on account of the clear, crystalline contents of the vesicles; in Scotland it is still called "crystalpox," and in England "glasspox." In England Heberden first described it in 1761 or 1776, calling it "Variolæ pulsillæ." The name varicella is said to have been given it by Vogel in 1764, this, like that of variola, being a diminutive of the Latin, varus, a pimple.

Karl Hochsinger of Vienna is of the opinion that variola and varicella are etiologically the same, and gives three cases presenting somewhat remarkable features in support of his argument. A lad aged ten years, the younger of two brothers, pupils at a school in which varicella had been more or less prevalent, was attacked with varicella and kept at home. The older brother, aged thirteen years, was also not allowed to attend school, and although not isolated he remained in the house with his brother and his mother, a lady forty years old, in order to prevent spreading the infection. On the twelfth day after the outbreak of the rash in the younger brother, the elder one and mother were taken sick at the same time. The boy presented a typical picture of varicella, but the mother had a severe attack of variola. All three had been thoroughly and successfully vaccinated. Hochsinger considers in these cases the diseases as etiologically the same but clinically different, while Thomas believes them all to have been variola. Von Jürgensen, commenting on the matter, says: "It is very strange that fifteen students of a gymnasium class, who belong to the higher classes of society and were still under the protection of vaccination, should at the same time have smallpox even in its lightest form, at a time when, as Hochsinger says, not a single case of variola vera was reported in Vienna. On the other hand, the simultaneous occurrence of varicella among so many children who were at just the limit of age when the susceptibility to the disease is lost is not less strange. Add to this that the mother, who, five years before, had been successfully vaccinated for the third time in her life, and thus, according to all experience, was strongly protected from smallpox, was infected with the slightest form of the disease and had to undergo the severe type. I cannot explain these strange phenomena. I only believe that this observation, standing as it does, by itself, does not apply to the question of identity."

Dr. Dawes himself thinks the age question to be the strongest argument in favor of the duality of the two diseases, and says: "Although cases of varicella do occur in adult life, it is, to all intents and purposes, limited to the first fifteen years of life, the very great majority of cases occurring before the patient has reached his tenth year. Variola, on the other hand, attacks all ages, and when it does attack children it is usually very severe and the mortality great." Again varicella is not an epidemic disease, except in very rare instances. Variola and varicella differ widely in their morbid processes. Writing of the morbid anatomy of varicella, in Gibson's Practice, J. W. Moore says: "Notwithstanding its appearance, the chickenpox is certainly not monocular. Its thin covering and superficial position result from rapid formation."

With regard to the unusual epidemic of which the author was in charge, he states that "thirty cases occurred in a boarding school for girls, the pupils numbering sixty-five and ranging in age from nine to nineteen years. The cases were all mild, only seven of the thirty being kept in bed more than one day, although all were isolated. Although in several cases the eruption was discovered only because it was being watched for, in others it was markedly abundant. . . . Among these cases I wish to call particular attention to the fact that nine gave the history of a previous attack in infancy, all had been successfully vaccinated, several of them twice, and fifteen within eight weeks by myself."

Four cases recurred within twenty days, one within twenty-two days, one within nineteen days, and the last within twenty-two days from the previous attacks.

Dr. Dawes has done good service in once again bringing forward the interesting point as to the identity of varicella and variola. There is undoubtedly something at least concerning which to argue, although there are but comparatively few physicians in the United States who will not contend that chickenpox and smallpox are essentially different diseases. At the same time when men like Kassowitz, Hochsinger, and von Jürgensen hold that such is not their conclusion, then it may be well to pause ere looking upon the question as settled.

---

**A Case of Fatal Poisoning Due to Injections of Mercury Salicylate.**—Neubeck reports the case of a woman, thirty-six years old, suffering from a generalized syphilitic exanthem, who received subcutaneously (in three doses) 2.5 grams of a 10 per cent. paraffine suspension of salicylate of mercury. Three weeks after the last injection toxic symptoms appeared, with high temperature, diarrhœa, aggravated skin eruption, and mild stomatitis. On the fourteenth day gangrene of the posterior vaginal wall produced a rectovaginal fistula. Death followed four weeks after the beginning of toxic symptoms. At the autopsy there were found abscesses in the gluteal region filled with thick pus, and ulceration of the intestines. No mercury was found in the contents of the abscesses. Three other fatal cases due to salicylate of mercury have been reported. Thirteen fatal cases due to calomel are on record.—*Dermatologische Zeitschrift.*

### Yellow Fever Aboard Ships.

Dr. Francis W. F. Wieber, Surgeon U. S. N., writes in the October number of the *Journal of the Association of Military Surgeons* concerning the above subject. The writer has had access to the records of the Bureau of Medicine and Surgery of the U. S. Department and has succeeded in unearthing a large number of valuable professional papers. Among others several were found dealing with yellow fever, and supplying much recent data on the disease. The general conclusions arrived at by Dr. Wieber were as follows: (1) Persons on board of a ship anchored at some distance from shore in a yellow-fever port, may become primarily infected with yellow fever, without having set foot on shore. (2) The infection thus caused has been traced, directly or indirectly, to the taking in of stores and provisions. (3) Secondary cases have frequently happened on board ships at a considerable distance from shore. These continued after the ships left port. (4) Epidemics on board men-of-war have been prevented by the timely isolation—sending on shore—of early cases. (5) In some instances an epidemic has not developed on ships after yellow fever had appeared, even when it was impossible to send the sick away from ship in the very beginning of the attack. (6) First cases have occurred from the sixth to the twelfth day after leaving port. (7) Transferring a ship's crew from an infected vessel to an uninfected vessel put a sudden end to the epidemic. (8) The sick transferred from an infected vessel do not necessarily cause new foci. (9) Freezing a ship for an extended period, combined with repeated fumigations, under special conditions does not necessarily kill the morbific agent.

The history of numerous epidemics of yellow fever which have occurred on board ships of the United States navy is given briefly by the author. The value of the data thus obtained is explained on the grounds that a ship is generally more or less isolated, having little intercourse with the shore. Even, however, under such conditions epidemic disease has reached vessels of our navy, and the record of 40 per cent. of the complement of a ship taken sick with yellow fever, and of a death rate of 44 per cent. of the sick, as happened on the *U. S. S. Jamestown* in 1867, while at Panama during the dry season, furnishes an experience well worth considering.

As the fact that yellow fever is transmitted by means of infected mosquitos is now believed to be beyond cavil, such insects must have reached the ships either blown thither by the wind or conveyed in clothing or provisions.

### Educational Standards of the Medical Profession of New Jersey.

The State of New Jersey has ever been foremost in raising the standard of medical education within her borders, and in this respect has set an excellent example. Dr. E. L. B. Godfrey of Camden, N. J., has recently delivered an address on "The Educational Standards of the Medical Profession of New Jersey, Past and Present." The address was given before the Medical Society of New Jersey, at its annual meeting, June 23, 1903, the matter contained therein being of the greatest interest not only to the medical profession of New Jersey but to physicians in all parts of the country. The subject of interstate endorsement was dealt with at some length by Dr. Godfrey, who, from the standpoint of eight years' experience as secretary of the New Jersey State Board of Medical Examiners, can write with a considerable amount of authority.

Referring to the question of endorsement of licenses issued after examination by other States, the writer describes the situation as being perplexing, and then goes on to say: "This perplexity arises from four causes. The unsettled state of medical education throughout the country; the wide variation in the curricula of the 156 medical colleges, in respect to their entrance examinations, methods of teaching, and requirements for graduation; the differences in State laws regulating medical practice, arising from the varying needs of different States according to their public school standards and extent of population; the diversity of opinion in the profession itself as to what should be required to obtain the title of Doctor of Medicine and State authority to practise, contribute complications to the solution of the question on a common and equitable basis."

The point is discussed as to which seem the most applicable and effective steps to be taken to settle the matter. Dr. Godfrey draws attention to the fact that of the fifty-four States and territories of the Union, as far as can be ascertained, only five have compulsory reciprocity embodied in their statutes; while in the remaining forty-nine endorsement is optional with the licensing authorities or not provided for by statute. The reasons which, in the opinion of the writer, can be adduced to prove its injustice to the profession and its detriment to the State, are as follows: (1) It makes a State medical certificate paramount to a diploma from the highest medical colleges and to the qualifications of the most distinguished practitioners in the question of endorsement, whereas such certificates should be regarded as only co-equal with the several conditions of endorsement, in justice to the profession and the colleges. (2) The system is mandatory and places an embargo on applicants of professional merit from States that cannot reciprocate by reason of higher requirements. This may be illustrated by the recent refusal of a certain State to accept the New Jersey certificate because New Jersey could not reciprocate on account of its higher standards—an injustice at once manifest. (3) Its application is limited, because State medical laws are not uniform, and the limitation will continue for years on account of differences in population and in the grade of public schools in the different States. (4) Its tenure also is uncertain. The changes continually being made in State laws to keep in touch with the progress of medicine will cause constant interruption of endorsement and consequent confusion and hardship to the profession. (5) It is contrary to the formulated ethics of the profession, because it is a revival of the "lex talionis" of the ancient codes.

There can be but slight differences of opinion among the members of the medical profession of the United States with regard to the need of some form of medical reciprocity between the States. The difficulty is with respect to the form this reciprocity should take. At any rate New Jersey has done well in pointing the way toward raising the standard of medical education throughout the country generally.

**Female Medical Students in Germany.**—Only one woman received a doctor's degree from a German university in 1900, but in 1902 there were fourteen women medical graduates—five from Halle, three from Heidelberg, two from Göttingen, and one each from Berlin, Breslau, Munich, and Freiburg.

### A Fatal Case of Poisoning by Sulphate of Quinine.

Col. R. H. Quil of the Royal Army Medical Corps writes in the *Journal of the British Royal Army Medical Corps*, October, on this rare form of poisoning. He gives a description of a case of poisoning by sulphate of quinine which came under his immediate notice. A soldier who was at the time a patient in Fort Pitt Hospital, Chatham, was assisting in the removal of some equipment from a cupboard which also contained some stock bottles of medicine, when he suddenly seized a bottle and swallowed its contents. It was found that the bottle had contained eight ounces of a concentrated solution of sulphate of quinine, there being in all 320 grains of quinine. At the lowest computation it was estimated that at least 240 grains of quinine must have been held in solution and taken. The man quickly complained of vomiting and retching, which was furthered by an emetic which had been at once administered.

On the arrival, within five minutes, of the Orderly Medical Officer, the patient was unconscious, the face of a ghastly paleness and bedewed with clammy perspiration, pupils widely dilated, and insensible to light and touch. Respiration greatly impeded, slow and spasmodic, while the pulse was barely perceptible. The treatment resorted to was active stimulation produced by means of brandy and beef tea per rectum, sinapism to nape of neck, frictions with brandy over the cardiac region, and hypodermic injection of digitalis and ether, these measures had the effect of restoring the pulse to a large extent, but in all other respects the condition remained unchanged. Soon, however, the pulse began to weaken, and in a short time was not discernible. The pulse was again revived by active stimulation, but artificial respiration had no beneficial effect. After active stimulation had again been discontinued the pulse once more failed and became completely lost. The pulse appeared and disappeared at intervals until 7.30, at which time it ceased to beat entirely, and a species of convulsion, which affected principally the lower extremities, was followed by death.

Colonel Quil in his remarks on the case said that the man had been in the hospital but a few weeks, and his general health appeared to be good, although a comrade who slept in an adjoining bed thought that he had exhibited slight signs of mental aberration. The stomach pump which was the remedy most likely to have had the desired effect was unfortunately not used, nor was strychnine injected subcutaneously.

---

### Dirty Milk Cans in New York.

The *New York Tribune* of November 8 has a timely article upon the above subject. It is pointed out that although immense strides have been made toward obtaining a pure milk supply for the city, and that to reach this end almost every conceivable measure has been put into force, yet one simple but necessary precautionary means has been neglected. Milk cans are still wofully misused. According to the writer of the article the farmers are not to blame for this state of affairs. W. W. Hall, Secretary of the New York Dairymen's Association, sent the following letter to the *Tribune* which expresses the sentiments of the maligned dairymen and points out some of the abuses:

"The principal abuse to which I call your attention is the fact that no attempt is made to clean the cans before leaving the city. The little amount of milk which adheres to the inside of the vessel as it is emptied varies in quantity, according to the length of time the can is allowed to drain. These cans do not reach their owners for many days and sometimes for weeks. Milk being such a favorite medium for the propagation and growth of bacteria, the milk thus retained is thoroughly decayed upon the arrival of the cans. If they were new, they, no doubt, could be cleansed sufficiently to be used again in refilling with milk and cream; but a great many of them are old and the tin has become worn so that the iron is exposed. This being porous, it absorbs and retains germ life from the decayed milk and renders the milk utensil unfit for further use. In addition to this, some persons who are connected with the business at the New York end or the railroad men are guilty of various other things. A gentleman told me recently that he had taken the covers from cans which contained decayed eggs. The manner of cleaning these cans at factories before refilling with milk and cream is not at all thorough. Many of the shipping stations have poor conveniences. The stench arising from the cans is such that the ordinary shipping station assistant will not decently prepare them, and, having assisted in attempting to cleanse them, and having inspected the cans after the cleansing had taken place, and knowing that the stench remains as before in many of the cans, I cannot criticise the can-washer."

To this severe indictment of the manner in which milk cans are misused is added many more details which go to show that reform is needed, so far as the proper cleansing of milk cans is concerned. However, quite enough has been quoted to prove the case against the city milk dealers with regard to their carelessness concerning the cleanliness of their milk cans. It is a serious matter and should be looked into, and steps taken to compel the city milk dealers to do their duty by the public in this respect.

---

### Venereal Diseases in Armies.

Venereal disease is one, if not quite the most fruitful, cause of undermining the health of the soldier in armies the world through. The report of the Surgeon-General of the army of this country shows too plainly that American soldiers contract venereal diseases as freely as do the fighting men of other nations. During 1902 13,000 admissions were from this cause, equivalent to a rate of 160.94 per thousand.

The *Journal of the Royal Army Medical Corps* for October, referring to the recent issues of the report of the British Army Medical Department, and that of the Sanitary Commissioner with the Government of India, remarks that "those portions of the report which deal with the health of the British army during the year 1901 are not altogether reassuring as to the means of control over venereal disease among soldiers." The admissions in the United Kingdom numbered 10,631. The total ratio of admissions for venereal diseases was 105 per 1,000 of strength, being higher than the preceding year's ratio by 12, but lower than the average of the preceding ten years by 52 per 1,000. The disease was most prevalent, however, among the colonial garrisons, in Barbadoes, China and Jamaica, where the admission ratio was respectively 282, 260, and 198. The admission rate in India among European troops showed some improvement, the ratio per 1,000 being 276, considerably below the ratio for the preceding ten years.

These figures are sufficiently convincing evidence of the frightful havoc wrought among both American and British soldiers by venereal diseases, and thrice blest would be the man who could devise some

means of staying this evil. Surgeon-General R. M. O'Reilly is decidedly of the opinion that the abolition of the canteen is largely responsible for the steady increase of venereal diseases in the United States army, for the reason that the soldier is now subjected to the temptations to intemperance and vice attendant on the expenditure of a full month's pay at the low resorts infesting the outskirts of our military reservations. Probably this is the view taken by the majority of those who are competent to speak with authority. The writer in the *British Army Medical Journal*, to which reference has been made, thinks that the reduction in the rate of admissions for venereal disease among the European troops in India is largely due to a greater interest taken in the matter by officers generally, the provision of means of ablution in barracks and the encouragement of their use, lectures on temperance and continence, the fostering of athletics among the men, the imposing of disciplinary restrictions on soldiers constantly admitted to hospital for venereal disease, and the placing of certain localities out of bounds. Such measures, if conscientiously carried out, would help to stem the tide of vice, and would be in the interests of both morality and health, and are at least worthy of a trial.

## News of the Week.

**The Operation on the German Emperor.**—The Berlin correspondent of MEDICAL RECORD cables under date of November 14 that the operation on Emperor William's throat was eminently successful in its results. It was performed under cocaine, the tumor being snared off after its rather broad base of attachment to the left vocal cord had been partially dissected away. There was considerable loss of blood, but the bleeding ceased spontaneously in a short time. Examination of the tumor showed it to be composed of a rather soft connective tissue, poor in cells, completely delimited from the surrounding tissues by a cell membrane, and containing pigment granules, the remains of former slight interstitial hemorrhages. The diagnosis was polypus of the left vocal cord. In a report of the operation published in the *Frankfurter Zeitung* of November 13, and believed to have been written under the direction of Dr. Schmidt, the operator, who is a resident of Frankfort, it is stated that the result of the microscopical examination was in the hands of the Emperor and his physicians six hours after the operation. This unexcelled record in rapid hardening, staining, and section-cutting was due to an invention of Professor Orth, which was used for the first time, but the description of which has never been published. The final bulletin of the surgeons in attendance, v. Leuthold, Schmidt, and Ilberg, was issued on Tuesday of this week. It read: "The healing process of the left vocal cord of His Majesty continues regularly. No more bulletins will be issued."

**The Warren Triennial Prize** was founded by the late Dr. J. Mason Warren in memory of his father, and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation, considered worthy of a premium, on some subject in physiology, surgery, or pathological anatomy; the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. Dissertations must be legibly written, and must be suitably bound, so as to be easily handled. The name of the writer must be enclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying dissertation. Any clew given by the dissertation, or any action on the part of the writer which reveals his name before the award of the prize, will disqualify him from receiving the same. The amount of the prize for the year 1904 will be $500. In case no dissertation is considered sufficiently meritorious, no award will be made. Dissertations will be received until April 14, 1904. A high value will be placed on original work. Papers may be sent to Dr. Herbert B. Howard, resident physician, Massachusetts General Hospital, Boston, Mass.

**The Silliman Lecturer at Yale.**—Dr. C. S. Sherrington, F.R.S., Holt professor of physiology in the University of Liverpool, has been invited by the Faculty of Yale University to succeed Dr. J. J. Thomson, F.R.S., professor of physics in the University of Cambridge, as lecturer under the Silliman Memorial Endowment. The lectures will be delivered at Yale University in the spring of 1904.

**Site for the New State Hospital.**—The committee of the State Lunacy Commission appointed to select a site in Washington County for a new State Hospital for the Insane, after a consideration of nine places has definitely rejected five, and will soon select one of the remaining four. The requirements are that the site shall contain at least 1,000 acres, and that it shall be within easy access by railroad and other means of communication. All of the sites now under consideration meet these requirements.

**The Manic Depressive Psychosis.**—Dr. Walter D. Berry writes that the dropping of quotation marks in the typewritten copy of his article with this title, published in the MEDICAL RECORD of October 3, has done an unintentional injury to Dr. Henry P. Stearns of Hartford. The latter part of the article beginning with (Stearns says) "the *modus operandi*," etc., and ending with "eliminate the weaker ones," was a quotation from the Report of the Superintendent in the Seventy-second Annual Report of the Officers of the Retreat for the Insane at Hartford, Conn., and this fact should have been marked by inverted commas.

**Uniformity in Vital Statistics.**—At the recent meeting of the American Public Health Association, held at Washington, the Committee on Vital Statistics reported that effective coöperation had been instituted between that association, the Conference of State Boards of Health, the American Medical Association, the United States Census Bureau and the United States Public Health and Marine Hospital Service for the improvement of the vital statistics of this country. Among the objects sought are the extension of adequate methods of registration, the use of uniform and comparable tables and rates in bulletins and reports, and the improvement of the international classification of causes of death. A pamphlet on "Statistical Treatment of Causes of Death" has been issued by the United States Census Bureau, requests for which should be addressed to Mr. W. A. King, chief statistician for vital statistics, Census Bureau. It has especial reference to the difficulties encountered in compiling deaths returned from several causes, and asks for the coöperation of the profession in framing a thoroughly satisfactory method of procedure in such cases.

**Street Accidents in New York.**—It is reported that 538 persons were killed by vehicles in the streets of this city during the year 1902. Compared with this, the mortality from the same course in London during the same period was only 158. The difference is in part due to the more rapid rate of progression of our trolley cars compared with the leisurely trams and still slower buses of London, but much is also

due without doubt to the more efficient management of street traffic by the London police.

**Disappearance of a "Case."**—While the members of the Newburg Bay Medical Society were holding a meeting in the reception room of the Matteawan Hospital, on November 10, and several patients were before them as subjects of discussion, one of them broke from two attendants and escaped. A reward has been offered for his capture.

**The Mystery of Miss Hickman's Disappearance Explained.**—At the conclusion of the inquest, held November 12, into the death of Miss Frances Hickman of London, the woman doctor who disappeared from one of the hospitals and whose body was found a long time afterward in a secluded part of Richmond park, the jury rendered a verdict that she committed suicide while temporarily insane. It was thought by many that she was the victim of foul play, as she had no apparent reason to take her life, but the finding by her side of a bottle which had contained poison, and the absence of any sign of violence led to the finding of the verdict mentioned.

**Diphtheria in New Jersey.**—Several towns in New Jersey are threatened with epidemics of diphtheria. In New Brunswick the Health Board is hampered by the exhaustion of its appropriation, and there is no way of securing more money until the spring. During the first ten days of this month there were thirty-five new cases reported, while during the entire month of October there were but five. In Montclair there has been friction between the Health Board and the School Board. There were twenty cases reported during the first ten days of the month, and the Board of Health ordered the closing of the schools. But the Board of Education did not take the same view of the situation as the Health Board, and the order of the Health Board was ignored, and two of the Central and Mt. Hebron schools were open as usual, the day after the order was issued.

**The Pathological Society of Philadelphia.**—At a stated meeting, held November 12, Dr. W. M. L. Coplin exhibited a specimen of chronic adhesive peritonitis, with multiple non-obstructive angulations of the colon; Dr. Morris J. Lewis and Dr. Robert N. Willson, a specimen of carcinoma developing in and from a gastric ulcer; Dr. William Pepper, one of carcinoma of the heart secondary to carcinoma of the penis; Dr. C. C. Norris, a specimen of primary carcinoma of the appendix, with report of a case; Dr. W. T. Longscope, one of primary carcinoma of the pancreas, and he reported two cases of primary carcinoma of the gall-bladder; Dr. J. D. Steele presented a communication entitled "Ulcus Carcinomatosum."

**Ear-grafting.**—An experiment has just been made in Philadelphia in the transfer of the entire pinna of the right ear from one man to another. The recipient of the ear was a man from the West who had lost that ornamental appendage and, being about to wed, wished to have the symmetry of his head restored. The donor was a resident of this city who parted with his auricle on consideration of $5,000. Although the donor signed a bill of voluntary sale of his ear, it was thought best to perform the operation outside of the State in order not to incur the risk of a charge of mayhem under the New York State law.

**Philadelphia County Medical Society.**—At a stated meeting, held November 11, Dr. Mihran K. Kassabian read a paper on "The Technique of Röntgen-ray Treatment." He discussed the several forms of apparatus employed, together with their method of application, the time and mode of exposure and the conditions to which the treatment is applicable. Dr. G. E. Pfahler presented a communication entitled "The Röntgen Ray in the Treatment of Carcinoma and Tuberculosis," reciting an illustrative group of cases showing the usefulness, as well as the limitations, of the procedure. Dr. Wm. M. Sweet read a paper on "The Röntgen-ray Treatment of the Eye and its Appendages." He pointed out that the greatest good with reference to the eye had been in the diagnosis of the presence and of the location of foreign metallic bodies and their removal, especially by means of powerful magnets. Epithelioma on and about the orbit has proved amenable to the treatment and some success has been observed in the application of the same measure for the relief of trachoma. Dr. Henry K. Pancoast presented a communication dealing with "The Röntgen-ray Treatment of Keloid." In the cases in which such treatment had been pursued it was found that the applications had to be made for a long time, and the possibility of recurrence was by no means excluded. Dr. Jay F. Schamberg read a paper entitled "The Finsen Light and the Röntgen Ray in the Treatment of Diseases of the Skin." The results from the employment of the Finsen light had been disappointing, although some good had been accomplished in cases of lupus vulgaris and lupus erythematosus. Better results, perhaps, were obtained with the aid of the Röntgen rays, not alone in the disorders mentioned but also in a variety of others. The important recommendation was made that when feasible, surgical measures should not be neglected, and thus valuable time lost. The light-treatment is especially indicated when surgical measures are not applicable or when the diseased condition is inaccessible to such measures, and also after operation had been performed. In the discussion, which was participated in by Drs. Chas. Lester Leonard, M. B. Hartzell, W. S. Newcomet, John B. Shober and W. L. Rodman, the utility of the Röntgen rays was pointed out, further, in cases of Paget's disease of the nipple and malignant diseases of the pelvic organs.

**New York State Association of Railway Surgeons.**—the thirteenth annual meeting of this society was held at the New York Academy of Medicine, November 12, under the presidency of Dr. Henry Flood of Elmira, N. Y. The following officers were elected for the ensuing year: *President*, Dr. Charles G. J. Finn of Hempstead, N. Y.; *First Vice-President*, Dr. E. P. Conn of Concord, N. H.; *Second Vice-President*, Dr. Joseph P. Creveling of Auburn N. Y.; *Secretary*, Dr. Geo. Chaffee of Brooklyn, N. Y.; *Treasurer*, Dr. J. K. Stockwell of Oswego, N. Y. On the day following the meeting Dr. Joseph A. Blake gave a general surgical clinic at Roosevelt Hospital in the morning, and Dr. Frederick H. Wiggin, at the City Hospital, Blackwell's Island, in the afternoon. It was decided to enlarge the membership in the society so as to include surgeons from the New England States, and the name was accordingly changed to "The New York and New England Association of Railway Surgeons." Twenty-one new members were elected.

**College of Physicians of Philadelphia: Section on General Medicine.**—At a stated meeting, held November 9, Dr. T. L. Coley presented a communication entitled "A Case of Stricture of the Œsophagus, Complicated by Subdiaphragmatic Abscess, Loculated Empyema, and Purulent Peritonitis." The patient was a man, who swallowed liquid solder with suicidal intent. Life was prolonged for a number of weeks, and after death the œsophagus was found constricted near the cardiac orifice of the stomach, with dilatation above this situation. Although there was no evidence of rupture, the abdominal viscera were matted together by inflammatory adhesions and a collection of pus was found beneath the left half of the diaphragm, and also three loculated

abscesses in the left pleural cavity displacing the lung and occupying the intervals between its lobes. Dr. Wm. G. Spiller read a paper entitled "Two Cases of Paraplegia Occurring in Smallpox, with Necropsy." Paralysis in the course of variola is not a common complication, and when it occurs it has been attributed to various lesions of the peripheral nerves, the spinal cord and the cerebrum. Of the two cases reported only the brain and cord preserved in alcohol were obtained in one and no lesion was discovered. In the second case lesions of a somewhat diffuse myelitis, involving, however, more especially the gray matter and particularly that of the anterior horns, were present. Drs. J. A. Scott and C. M. Montgomery presented a paper entitled "Some Statistics Regarding Croupous Pneumonia, Especially Concerning Its Treatment with Carbonate of Creosote." The constancy of the mortality from pneumonia over long periods of years was pointed out, and the likelihood of error from a consideration of small numbers of cases or of collections of cases from a large number of sources. In the Pennsylvania Hospital the mortality during a decade has been about 24 per cent., though ranging in different years from 11 to 27 per cent., the differences bearing no relation to the actual number of cases, in which likewise there were marked variations. Of seventy-two cases treated with creosote carbonate the mortality was but 14 per cent. and if only the larger of the groups of cases studied were taken into account, leaving out the smaller number with a disproportionately large number of deaths, the mortality would have been even considerably lower. The drug was given in doses of from 3 to 5 minims in the case of children and of from 5 to 15 minims in older persons. No harm was observed, but the conclusion was reached that despite the apparently better results from this mode of treatment these might have been merely accidental and not attributable to the drug used.

**A Proposed Bureau of Water Inspection.**—Dr. Daniel Lewis, State Commissioner of Health, will, it is reported, ask the next Legislature for an appropriation of $10,000 to establish a new bureau in the department to be known as the Bureau of Water Inspection and Drainage, with special reference to summer resorts. If this bureau is established, there will be obtained and kept on file in the State Health Department data regarding the water supplies and plumbing and drainage equipment at hotels and farmhouses, so that intending guests can learn of these essentials to health before going on their vacations.

**The Late Drs. O. A. White and L. P. Walton.**—At a meeting of the Medical Association of the Greater City of New York, held November 9, 1903, the report of a committee appointed to prepare a suitable minute on the death of Dr. Octavius A. White was received and adopted. It was devoted to a eulogium of the character and eminent services of the deceased, and included a tribute from the *Oakland* (Cal.) *Tribune* of May 28, 1903. The conclusion of the report was as follows: "With a public life full of noble achievements for suffering humanity and a home life illumined by the most charming of domestic traits, his memory will be cherished for years that are to come by all who knew him.

"Your committee, in presenting this minute, unanimously offer the following resolutions:

"*Resolved*, That in the death of Dr. Octavius A. White this country and community have lost a valued citizen and our profession of medicine an honored member.

"*Resolved*, That we extend to the bereaved family of Dr. White our profoundest sympathy for them in this their period of bereavement.

"*Vivat post funera virtus.*"

THOMAS E. SATTERTHWAITE,
JOHN G. PERRY,
REYNOLD WEBB WILCOX,
} Committee.

At the same meeting a report on the death of Dr. Luis P. Walton was also received and adopted. In this minute it was stated that Dr. Walton "was one of the few representatives of the old school of general medical practitioners, and in that capacity he occupied a position of peculiar confidence and affection in the hearts of a large number of patients. They sought his advice in many other matters besides those appertaining to their physical ills, and they always found in him a patient and sympathetic listener and a sound and earnest adviser. Few who have not been general practitioners themselves can realize the extent of the responsibility and of the unremitting toil involved in caring for a *clientele* as large as his. He was a genial, kindly gentleman of wide sympathies and general interests, with a vigorous, active, masculine intellect; always cheerful, courageous, sympathetic, and ardently devoted to his friends. For public professional honors and appointments he cared but little, but he was ever loyal to the profession of medicine, and generous in his dealings with its members." GEORGE L. PEABODY,
HENRY S. NORRIS,
} Committee.

**Obituary Notes.**—Dr. CHARLES MARSHALL of Huntingdon, Quebec, died suddenly of apoplexy at the house of a relative in this city on November 13. He was a graduate in medicine of the University of Bishop's College, Montreal, in the class of 1876. He was a member of the Medical Board of Governors of Quebec.

Dr. CHARLES J. VINCENT, formerly of this city, died at Bisbee, Ariz., on November 13. He went to Arizona about a year ago on account of failing health.

Dr. JAMES MCFADDEN GASTON died at his home in Atlanta, on November 15, at the age of seventy-nine years. He was a graduate of the Medical College of the State of South Carolina in the class of 1846. He was prominent during the Civil War as a medical officer in the Confederate service. After the war, from 1865 to 1883, he made his home in Brazil, practising among the colony of Southerners which was established in that country. Since 1883 he had been at the head of the department of surgery in the Southern Medical College in Atlanta. In 1895 he was president of the American Academy of Medicine, and in 1896 he was president of the Southern Surgical and Gynecological Association.

DR. GEORGE JULIUS ENGELMANN, formerly of St. Louis, but recently a resident of Boston, died from pneumonia in Nashua, N. H., on November 16. He was born in St. Louis, July 2, 1847, and was graduated in arts from Washington University in 1857, receiving the degree of A.M. three years later. From 1867 to 1873 he studied medicine in Europe, receiving the degrees of M.D. from the University of Berlin in 1871, and of master of obstetrics at Vienna in 1872. He was a surgeon in the Franco-Prussian war in the years 1870-71. He practised in St. Louis from 1873 to 1897, removing in the latter year to Boston. He was widely known as a gynecologist, and taught that specialty for many years in the Missouri Medical College. He was also an extensive traveler, and was deeply interested in archæological and ethnological researches. His collection of Missouri flints and pottery is now in the Peabody Archæological Museum at Cambridge, Mass.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

MR. CHAMBERLAIN, TROPICAL MEDICINE AND VIVISECTION—THE QUEEN AND OLD BART'S—CHARITY DINNERS—HOSPITAL BUILDINGS: TEMPERANCE AND WATERLOO HOSPITALS—OUT-PATIENTS AND REARING CHILDREN—CANCER AND NERVE AREAS—PROSTATECTOMY—ECTOPIC PREGNANCY—EYE-TESTING—SPECTACLE-MAKERS' DIPLOMAS—HOSPITAL FUNDS—HOSPITAL SHOPPING DAY—NORTH LONDON CONSUMPTION HOSPITAL.

LONDON, October 30, 1903.

We are just now living in an atmosphere so agitated with exciting controversies that it requires some effort to detach ourselves from general debates to a consideration of medical matters. On Monday next the municipal elections take place, when sanitary and medical questions will probably obtain less consideration than usual, on account of the absorbing political movement. It is, however, worth noting that Mr. Chamberlain, by far the most considerable figure in the present world of politics, has found time in the midst of a most arduous campaign, to show once more his interest in tropical medicine. Yesterday afternoon he spent an hour in the Liverpool University, where he had an enthusiastic reception from the students, but excused himself from the request for another speech. A visit was afterward paid to the Royal Southern Hospital, the headquarters of the Liverpool School of Tropical Medicine, where he was received by the president, Sir Alfred Jones, and displayed great interest in the arrangements. It is reported that during the visit one of the nurses went to the piano and played "For he's a jolly good fellow," and the refrain was taken up by the patients. Thus a feeble echo of the excitement outside penetrated the seclusion of the hospital.

The antivivisectionists tried to draw from Mr. Chamberlain an expression of his views for a meeting they got up on Tuesday at Birmingham to protest against a license being granted to the University, of which he is Chancellor. He replied, "I am most certainly opposed to the torture of animals, but entirely approve of the application of the authorities of the University for a license to promote scientific research. I think it is a cruel libel on men like Sir Oliver Lodge, Dr. Windle, and others to attribute to them the possibility of any act of cruelty. I shall be obliged if you will read this letter to the meeting which you propose to hold."

Her Majesty the Queen has sent to the Lord Mayor £1,000 to start the appeal for funds for the enlargement and improvement of St. Bartholomew's Hospital in accordance with the recommendation of the Mansion House Committee. His Majesty the King was president of the hospital from 1867 until his accession, when he became patron, his place of president being taken, at the unanimous request of the governors, by the Prince of Wales. There will be a meeting of the governors next Thursday to consider and take action on the report of the committee on the scheme for extension of the buildings and general improvement of old Bart's.

Sir H. Burdett is still dissatisfied with the scheme of the committee and advocates, in this week's issue of his paper, the purchase of additional land so as to increase the site from six to eight or eight and a quarter acres. He says the £600,000 required for that plan could easily be raised in five years if the public were satisfied that it would perfect the hospital.

A new departure as to charity dinners may interest you. His Royal Highness the Duke of Connaught has agreed to preside at a dinner in aid of the Home and Hospital for Incurable Children, when a new method will be inaugurated, viz., no gentlemen will be invited to become stewards, but a ladies' committee has been formed to invite other ladies to be stewards, bringing their own parties with them.

On Monday, Her Royal Highness, the Duchess of Albany laid the foundation stone of the new building of the Royal Waterloo Hospital for children and women which was founded in 1816. The new structure will be much larger than the old, containing about 200 beds instead of 54. It will cost £50,000, of which only £17,236 has been collected, inclusive of about £2,500 contributed in purses presented to Her Royal Highness on this occasion.

On Wednesday the Lord Mayor accompanied by the Lady Mayoress and the sheriffs with their ladies paid a state visit to the Temperance Hospital to inaugurate a scheme for rebuilding the out-patients' department. The extensive alterations needed will necessitate so large an outlay that, on the recommendation of King Edward's Hospital Fund, it has been determined to pull down the present structure and rebuild it. The King's Fund has granted £1,500 toward the £10,000 required, and no doubt the Lord Mayor's visit—the third that has been paid by chief magistrates of the city—will tend to increase the interest and contributions of the public. The hospital was founded in 1873. A wing was erected a few years later. More than 21,000 in-patients have been treated during its thirty years of existence. The Lord Mayor and sheriffs were conducted through the wards by Sir W. Job Collins, who is surgeon to the hospital, the statistics of whose operations I gave you in my letter of the 25th ult.

On Monday Dr. Edward Cantley read a paper at the Charity Organization Society on out-patient departments and the rearing of children. He pointed out how limited was the effect of the work done among the out-patients of children's hospitals and put forward suggestions for supplementing it. The mortality returns, he found, showed during the ten years, 1891 to 1900, a yearly average of 160 out of every 1,000 children born in London died under the age of one year. More than two-thirds of these deaths were caused by diarrhœa, which almost always arises from errors of diet or mode of preparing the child's food. Quite half the infants brought to the out-patient physician were under one year, and much of the energy spent in treating them was wasted. The benefit derived from the physician's advice was in inverse ratio to the mother's intelligence. The failure of the mothers to rear their children was due to three causes—ignorance, carelessness, or criminal neglect. Dr. Cantley suggested that steps should be taken to coördinate the efforts of charitable bodies and direct their attention to the possibility of assisting mothers in looking after their children by a system of home visits. He recommended the distribution, to mothers, of a pamphlet containing simple but full instructions about the handling and feeding of their babies from the day of birth. He sketched a scheme to enable them to obtain, at a reasonable price, good milk without encouraging the neglect of breast feeding. But with a good milk supply he thought it necessary to teach mothers how to make use of it, and therefore he would have well-trained women in connection with out-patient departments to visit cases selected by the physicians and teach the mothers how to keep milk from contamination, inculcate the importance of cleanliness in all utensils, and demonstrate practically how the food should be prepared and how the infant should be washed and clothed. Such a scheme, he thought, would meet the evils he had mentioned. Ultimately the education of the poor would give the best results, but progress in that way is slow and almost imperceptible.

At the Pathological Society Mr. G. L. Cheatle gave a lantern demonstration of cases connected with the relation of cancer to nerve or trophic areas. In a former paper he pointed out that rodent ulcers and squamous epithelioma occupied certain areas which he holds are nerve areas—sensory nerve areas. He, moreover, thinks the incidence of cancer frequently occurs at points where a nerve becomes cutaneous, and most frequently at those points which Dr. H. Head described as maximum points.

Prostatectomy was discussed at the same meeting by Mr. S. G. Shattock, who had examined the series of specimens presented to the Hunterian Museum by Mr. P. J. Freyer. The two points on which there has been considerable controversy are: (1) How far the prostate portion of the urethra is preserved, and (2) is the whole prostate removed. With regard to the urethra, its preservation is now regarded as of no consequence, though it is interesting to have the anatomical points cleared up. Mr. Freyer's operation is a prostatectomy, complete from the surgical aspect, but not histologically. In his specimens the transversely fasciculated character of the surface of the capsule showed that the line of enucleation was not beyond but through it. Mr. Shattock found that in most cases the prostatectomy was not complete from the histological side. He thought in this strict sense a complete prostatectomy could not be verified except by a microscopical examination of the parts left behind.

At the Obstetrical Society Mr. J. D. Malcolm related a case of extrauterine gestation with removal of a living fœtus of between three and four months' development. An incision was made in the middle line above the pubes, a small collection of pus opened, and the amniotic liquid evacuated. The cavity was packed with iodoform gauze and the placenta undisturbed—from July 24 to August 10, when an attempt to remove it set up so much hemorrhage that it was again packed. This killed the placenta, and there was little blood lost afterward, but every bit had to be peeled off the tissues, and the removal was not completed until August 26. The patient recovered.

Dr. Lockyer related a case of tubal gestation, which ruptured and the sac became implanted on the omentum. The ovum lived for about four months. An operation was eventually performed, but the patient died twenty-

four hours afterward. Some other cases were mentioned by Drs. Hellier and Bonney.

Mr. Herman took exception to the recommendation to operate promptly in all ectopic cases when the fœtus was living, whatever the duration of pregnancy. Certain dangers were present in the first half, but rare in the second half of the pregnancy—such a rupture of the tube or sac. When the patient arrived at term spurious labor came on, and the patient was not in much danger. At six months the placenta would almost certainly be thrombosed and could then be peeled off without hemorrhage. The safer way would be to wait for suppuration, which might occur at any time and might not occur at all, and the patient might enjoy fair health to the end of life with only the inconvenience of an enlarged abdomen.

To this objection Mr. Malcolm replied that he thought operation would be more dangerous after suppuration, or if it had to be done for severe hemorrhage. He had to admit that if operation was always done as soon as the condition was diagnosed some cases would be subjected to it which might do well without—such as the patient who carried the remains of a full-term fœtus for forty-three years, as recorded in the *Transactions*, Vol. 8, by Mr. Watkins, whose patient died at seventy-four years. Nevertheless Mr. Malcolm held, in view of all the circumstances, that delay was likely to result in the development of more dangerous conditions.

Some investigations have lately been made as to the testing of the eyesight of recruits for the army. It is probable that the dot test for sight will be replaced by Snellin's text types which are in use for candidates for commissions.

Since the Spectaclemakers' Company followed the example of the Obstetrical Society and granted certificates of competency, the town is filled with *diplomas* to deceive those who do not understand the difference between opticians and oculists. Pushed on by their trade, the company have asked the College of Surgeons its opinion as to the inclusion of sight-testing in their examinations. The council at their quarterly meeting gave a full reply pointing out the dangers of any unqualified person prescribing and closing a rather long but reasoned resolution as follows: "In the ultimate interest of the public no countenance should be given to any proposal which is likely to foster the belief that tradesmen, whatever be their technical skill, and whether opticians or orthopedic or other surgical instrument makers, are safe and sufficient guides in the management and treatment of deformities or other diseased conditions."

The Lord Mayor has received from Mr. George Herring £12,312 for the Hospital Sunday Fund in conformity with his promise to add five shillings to every pound collected. Last year, you will remember, Mr. Herring gave £11,575 in the same munificent manner. In the three preceding years he contributed £10,000. This year is a record—the total collection being £64,700, which is £2,000 more than in 1902.

It seems that "hospital shopping day" is to be kept, a large number of shopkeepers having promised to devote some portion of their takings (on Tuesday next) to the King's Fund. Each trader is asked to give something on that day, but how much is not to be suggested, still less is any disclosure of the amount of business done to be asked for of any trader. Each is to settle for himself whether he gives anything, and if he does, how much.

On Tuesday a new block of Mount Vernon Hospital was opened by the Marquis of Zetland (president). This will provide forty-five additional beds. This hospital, formerly called the North London Consumption Hospital, has made great strides of late. Up to 1880 only about twenty-five in-patients could be accommodated. In 1893 additions were made and sixty beds provided, subsequently increased again to seventy, and then one hundred. Of the forty-five new beds only twenty-eight can at present be occupied for want of money, which suggests to some that the building may be pushed on at a rate too fast for the resources.

## GONORRHŒA IN WOMEN.

To the Editor of the Medical Record:

Sir: The facts, as given by the late Dr. S. Seabury Jones, in reference to the failure of the working of the Contagious Diseases Acts in different European cities are a surprise to me. I had always supposed that the licensing of prostitutes, together with their compulsory examination, if properly carried out, was the best, in fact the only, means to limit and possibly to stamp out venereal disease. The figures quoted in your editorial—"Syphilis in Its Ethical Relations"—are discouraging. Still, I very much doubt the conclusions of Bergh, Le Bert, and Jones. The evil does not lie in the systematic examinations or the licensing of prostitutes, but in the manner in which the examinations are conducted.

The general practitioner seems to have a great deal to learn yet in connection with the diagnosis of venereal disease in women. Our medical and surgical works are very defective in this particular. I refer especially to the diagnosis of gonorrhœa. I am well within the mark in saying that if a class of graduates were asked what were the primary and most important symptoms of gonorrhœa in the female, 99 per cent. would answer, those of acute vaginitis, accompanied by purulent discharge, etc. That is wrong. Gonorrhœa is rarely a vaginitis; it is *a urethritis*, exactly as in the male. I have yet to find the case in which the disease does not lie primarily in the urethra. The extension to the uterus, ovaries, or Fallopian tubes is always a later manifestation of the disease either, by direct inoculation or by absorption of gonorrhœal poison. The inflamed area around the remains of the hymen is the result of irritation such as might arise by the presence of any unhealthy discharge, and is commonly present in simple leucorrhœa. *Every* case shows an initial "bladder trouble," as the patient usually expresses it—pain or burning on making urine and usually a desire to urinate more frequently. Very often, too, clear blood is passed at the end of the act. On making a careful examination pus can *always* be pressed from the urethra at this stage. The burning is rarely so severe as in the male, and does not last so long, for obvious reasons; but the disease remains as long, probably longer. It is usually overlooked by the examining physician, who sees the patient, say, five or six weeks later, and is probably forgotten by the patient herself. And that is where the whole trouble lies. At the moment of penetration the male and female urethras come together: it is unavoidable. At that instant inoculation from one to the other occurs. The woman may have used any quantity of corrosive sublimate, carbolic acid, potassium permanganate, or any other antiseptic solution a minute previously, and the man will not escape because the patient or the physician (probably the latter) has carelessly overlooked the source of infection when he made his final examination and found no unhealthy appearance of vulva, vagina, or uterus. The lesson we learn from these plain facts is—treat a woman suffering from gonorrhœa exactly as you would the male. Every patient should be ordered to take her copaiba or santal capsules and, if necessary, to inject mild silver, lead, or zinc solutions, etc., into the urethra at regular intervals. An ordinary male syringe, or dropper will usually suffice, or, better still, the continuous current of permanganate solution under the physician's supervision.

G. S. Scott, M.D.

Lampoc, Cal.

## Progress of Medical Science.

*The Boston Medical and Surgical Journal, Nov. 12, 1903.*

**Stomachal and Intestinal Derangements and Affections of the Fauces, Pharynx, and Air Passages.**—Beverley Robinson declares that at times we find the same microorganism in the throat and in the stomach. It is not known whether these microorganisms were swallowed or were originally developed in the stomach and brought into the throat by regurgitation. The writer believes that the condition of disordered stomach or bowels is not infrequently the cause of acute coryza. What is true of simple coryza is also true of acute catarrh of the nasopharynx, and of superficial acute tonsillitis of the simple variety. The dividing line between some cases of follicular tonsillitis and diphtheria is not easy to determine. The reactions of chronic disorder of stomach and bowels to nasal and nasopharynxeal catarrh were insisted upon as far back as 1882, by W. H. Daly. Each case must be treated by itself, according to its indications. The local faulty conditions of the air-passages should be treated, while, at the same time the habits should be regulated, and the diet be made moderate in quantity, simple and nutritious.

**Some Principles Involved in the Therapeutic Applications of Radioactivity.**—William Rollins writes that for the present, when using radioactive substances in internal therapeutics, the substances cannot themselves be employed, on account of their high price. However, when a radium salt is dissolved in water it gives off "emanations," which can be collected in air in a gas-holder over mercury, and used in internal medicine. Radium in solution can be depended upon as a constant source of emanation to be used in the therapeutics. Even the emanation itself can be employed to produce fresh radioactivity. As the radiations and emanations of the radioactive substances spread in all directions, and some of them are destructive to animal tissues, the radioactive substances must be used in tubes, cases, plasters, and so on, with non-radiable walls, in order that the activity may escape only in the

required direction, and be reinforced by the induced radioactivity from the inner surface of the container. Particular attention should be given to the protection of the eyes. Activity diminishes approximately as the square of the distance, though really more rapidly on account of the complex nature of the activity. Precautions, therefore, should be taken in regard to the distance of the apparatus from the part to be treated.

*Journal of the American Medical Association, Nov.* 14, 1903.

**Special Influences of High Altitudes on the Nose and Throat.**—S. E. Solly notes the following: (1) Surgical measures are often demanded at an altitude in cases which had previously gotten along comfortably without it at sea-level. (2) The results of such procedures are at least as satisfactory as elsewhere, but more than usual care must be taken to save all secreting tissue. (3) The local symptoms of atrophic rhinitis are aggravated though the constitutional conditions are often improved. (4) The moist form of hypertrophic rhinitis is much improved. Sinus diseases do better than at sea-level. Operative cases require less post-operative care than at a low level, and there is not so much danger of infection of wounds inflicted on tuberculous tissue. On tuberculous laryngitis, high altitudes effect a favorable influence. More cases recover and local treatment is more sucsessful than at lower levels.

**Arrested Tuberculosis.**—V. Y. Bowditch tabulates the subsequent histories of seventy-nine arrested cases of tuberculosis treated at the Sharon Sanatorium from 1891 to 1902. Of the entire number 15.2 per cent. died after varying intervals of comparative health. Of the remaining cases, sixty-seven in number, excellent accounts are received with only one or two exceptions, the former having sent no report at all of recent years. She was known to be feeling well at last accounts. The latter, a case of fairly well-marked disease, has failed in strength, and doubtless will sooner or later succumb to the disease. The majority write enthusiastically of their good health, some of them having left the sanatorium ten years ago. All are employed in their homes or in occupations which, as a rule, allow them to be out of doors more than before.

**Exercise as a Mode of Treating Diseases of the Heart.**—N. S. Davis, Jr., enumerates as possible methods, massage, Swedish gymnastics, mountain climbing, and resistance gymnastics. He states that drugs, as digitalis, may temporarily contract the heart when it is dilated, and strengthen it when it is weak, but permanent recovery of strength is obtained only by improving the nutrition of the organ, and by relieving it of excess of work. Both of these results are attainable by judicious exercise of the voluntary muscles. Unquestionably, the first or immediate effect of muscular work is to increase blood-pressure, but this rise is temporary, and is followed by a more persistent fall, which is caused by the dilatation of arterioles in the hard-used muscles, a dilatation necessitated by their demand for food, and for more rapid removal of waste by irrigation. The primary increase of pressure is in proportion to the degree of exertion, but the secondary fall is more dependent on the duration of muscular movements, and the number and size of muscles used. It is, therefore, possible, by trivial exertion, to avoid an increase of pressure, and by using many of the large muscles to ultimately lower pressure very gently. This is the reason for what may be called the first rule in applying exercise to the relief or cure of heart diseases—that is, the muscular effort must be slight, but numerous large muscles must be used. The second rule for the conduct of exercise for the relief of cardiac disease is naturally that respiration must be deepened, but not hurried, for quick, irregular and imperfect respiratory movements will lessen the variations in intrathoracic pressure, impede venous and lymphatic circulations. The third rule is that the exercise must be graduated. At first only the lightest should be used, and very gradually it must be increased in vigor, and it must be adapted to each case. Under no circumstances must breathing or the heart be hurried. Massage and resistance gymnastics are the gentlest forms of exercise, and should be first used in all cases.

*Medical News, November* 14, 1903.

**X-ray Treatment of Cancer of the Uterus.**—Sinclair Tousey explains the method of applying the *x*-ray to uterine cancer. The patient lies on her back with her hips at the edge of the table, the thighs vertical and legs horizontal, resting on the table crutches, which are about eighteen inches high. A sheet covers everything but the vulva, and after the speculum in introduced, sheet lead is spread over the buttocks and thighs to protect them from the *x*-ray. The *x*-ray tube ought to be a large and powerful one, and should be of medium hardness. The writer uses one of 40 cm. capacity. The tube and the current should be so adjusted that the bones of the hand may be faintly seen at a distance of two feet from the tube. For a beginning exposure the time ought not to exceed five or six minutes of actual *x*-radiation. The time is gradually increased, as a rule. In cases in which there is a fibroid or other tumor of the uterine body, the *x*-ray is placed about nine inches from the surface and directed at the tumor right through the abdominal wall. The time of exposure in this case may be altogether about nine minutes, while the treatment is directed to different parts of the abdomen during this interval. The third part of the treatment consists in the application of the high-tension discharge by means of vacuum electrodes. The results which may be expected are remarkable. The vacuum tubes bring about complete relief from pain, and the entire treatment results in a cessation of the discharge, disappearance of the odor, and a restoration to general health.

**Treatment of Tapeworm.**—Samuel P. Gerhard, after much experience in the treatment of this affection, has found a combination of male fern and pelletierine the most suitable. The following is his method: The loss of one meal is all that is required. The patient is instructed to clear out the bowels the day previous with one or two large doses of castor oil or salts. One dose may be given in the morning and one at night, an hour or two after a light supper. The next morning, as early as possible, a dose of pelletierine tannate, 20 grains, in two capsules, is given. When this has operated freely, in about two or three hours the following treatment is begun:

| | | |
|---|---|---|
| ℞ | Olei resinæ aspidii | ℥ii |
| | Ætheris | ℥ii |
| | Hydrargyri chloridi mitis | gr. xii |

M. et div. in capsulas No. XVI.
S. Two every ten minutes.

No food is taken during this time. In about two or three hours the worm will be expelled whole, with its head fastened to its neck. It is well for the patient to pass all of the bowel movements into a vessel of warm water on the morning the medicine is taken. No traction on the protruding worm should be permitted.

*New York Medical Journal, November* 14, 1903.

**Urinary Hyperacidity.**—T. R. Broun calls attention to a class of cases due to urinary hyperacidity but presenting the usual symptoms of cystitis, viz., frequent, painful, and burning micturition and occasionally a few blood and pus cells. Within two years he has met with ten cases with these symptoms, but a careful urinary examination determined that in every case the bladder was not involved. He finds that the cases most difficult to cure are those in which there is considerable irritation of the trigonum vesicæ due to the presence of marked symptoms over a long period of time. Treatment consists in keeping the urine bland and non-irritating, general hygiene and, if necessary, local measures under the strictest aseptic precautions. The principal point in diagnosis is to differentiate the condition from a true cystitis.

**The Fable of the Egg.**—W. S. Ely advocates the use of eggs in serious conditions of nervous exhaustion, pneumonia, diphtheria, and in fevers marked by high temperature and rapid waste. He often gives an egg every hour. This number is at times well borne, and has often lessened the necessity for alcoholic stimulants. Eggs may be taken in various ways, soft boiled, shaken with milk, but most easily, I think, raw, from a tumbler in which they are freshly dropped from the shell. The patient is instructed to swallow the yolk, enveloped in its membrane, and floating in its albumen. Passing over the tongue, the yolk elongates, fits the pharynx and œsophagus in the act of swallowing, and the mouth is left clean and free from any taste. Some moral force on the part of the patient, nurse, and doctor may be required to overcome a repugnance to the treatment referred to. Abstracts of several clinical histories are given. If nausea, vomiting, and diarrhœa supervene, it may be advisable to try the whites of the eggs alone. He states that he has given the whites of forty-eight eggs daily for many days in the critical stages of typhoid fever.

**A Case of Rupture of the Quadriceps Extensor Femoris Muscle.**—A. J. Ronginsky reports the case of a man aged fifty-eight years, who slipped and fell. Examination showed the lower end of the muscle at a point about three inches above the knee-joint; the patella was in front of the tibia below the tuberosity. A marked depression existed between the bones. Walking could be accomplished with the aid of a cane only. The greatest pain he experienced was when he attempted to lift his leg, as when walking upstairs. Operation was advised but refused by the patient. Four weeks later he was in the same condition with the exception of more pain around the joint. Fixation of the patella with adhesive plaster and tight bandaging of the thigh, to fix the muscle, relieved him for a few hours only. Later the author devised a sort of a brace, made of soft leather, to fit all around the lower border of the patella; and the patella was lifted up by

attaching adhesive strips from the lower end of the quadriceps to the sides of the leather supporter. The patient's gait greatly improved under this treatment.

*American Medicine, November* 14, 1903.

**Gallstones and Gastric Hyperacidity.**—J. Kaufmann believes that the relationship between gastric hyperacidity and gallstones is of more than theoretic interest. Hyperacidity and hypersecretion of the stomach play a more important rôle in gallstone disturbances than is generally admitted. Highly acid stomach contents upon reaching the duodenum, may cause a pyloric spasm. It is natural to conclude that spasm of the opening of the choledochus is brought about by the same cause. The constant irritation of the mucous membrane of the duodenum and frequent spasms of the opening of the choledochus may lead to chronic catarrh of the gall-ducts and thus to the formation of gallstones. Operation is not necessary in all cases of gallstones. When operation is not indicated, the internal treatment tends to set the stones at rest. The Carlsbad treatment is, as a rule, best in these cases. All disturbances of the digestive tract should be corrected in order to prevent further attacks.

**The Gastrointestinal Disturbances Associated with Migraine.**—John A. Lichty declares that migraine is an affection characterized by a paroxysmal attack in which the nervous and digestive disturbances are the most prominent and often the only symptoms. Patients of this class nearly always have a neurotic temperament. The digestive disturbances are rarely the first to appear. It is generally admitted that the chief cause of migraine is heredity. Various theories have been advanced to explain the cause and symptoms of migraine. The writer has tried the various methods of treatment which have been suggested by those who have thought that the cause of this disturbance has been found. The results have been far from encouraging. The writer has therefore put aside all ideas of specific treatment and has directed his efforts only to the removal of reflex causes and avoidance of exciting causes. Correction of the disturbances of the gastrointestinal tract has resulted in the reduction of the frequency and severity of the attacks of migraine in a number of cases, while in a few cases the attacks have ceased entirely.

**Chronic Malaria: Complications and Sequelæ with Special Reference to Digestive Complications.**—John C. Hemmeter states that the complications of malaria with typhoid fever can only be substantiated by the demonstration of the simultaneous presence of the typhoid bacillus and the malarial parasite in the same individual. As to the term "typhomalarial fever," which has been used to represent a third or hybrid form of fever not identical with malaria or typhoid, 80 per cent. of the cases of the originator of this term, classed as typhomalaria, were proved to be nothing else than malarial remittent. With the present clinical methods which show by blood examination the existence or non-existence of malaria by blood examination, and the widal reaction, confusion on these points should be done away with. As to the association of dysentery with malarial fever, the physician, in addition to his ability to recognize the malarial parasite, must also be able to recognize the various microorganisms that might cause dysentery. It is of the greatest importance that the physician be able to make blood examinations. The characteristics of chronic malaria are as follows: (1) During many months recurrences of malaria from time to time. These may be typical or masked attacks of chills and fever; (2) anæmia; (3) splenic tumor, eventually together with liver enlargement; (4) the same species of malarial parasite is demonstrable in the blood during the entire time; (5) decline of the general constitution. The writer calls attention to various complications of malaria besides those of the digestive system. Malarial cachexia is spoken of as a sequelæ, as is also hypertrophy of the heart.

*The Lancet, November* 7, 1903.

**The Prevention of the Recurrence of Nasal Polypi.**—E. S. Yonge calls attention to the necessity of removing more or less of the underlying bone, in order to prevent recurrence of the nasal polyps. To gain free access to their usual site it may be necessary to remove the middle turbinate in part at least. This can be done with cutting forceps, the area being anæsthetized with 10 per cent. cocaine applied on narrow gauze strips carefully tucked in about the turbinate. In severe cases of multiple polypi, especially those associated with ethmoidal suppuration, the method of Lack may be employed. The essential part of this operation is the thorough scraping of the lateral mass of the ethmoid with a large ring knife. The operation approaches the dangerous region of the cribriform plate, and should be performed with a large ring-knife, the finger being introduced from time to time to determine the condition of the parts, and note the progress made.

**A Case of Pleuropneumonia accompanied by Abdominal Disease.**—P. Rose reports the case of a girl of five years, who died of pneumonia. Before death a lump had been noticed in the right iliac fossa. The patient had evidently had abdominal pain and tenderness. She passed a little flocculent stained mucus, but no blood, although she strained considerably while at stool. A diagnosis of intussusception was made. None was found, however, at the autopsy, which showed, in addition to the lung condition, that the region of the ileocæcal valve was affected. For about one inch to one and a half inches on both sides of the valve, there were recent crimson extravasations of blood in the submucous tissue, presenting flame-like patches half an inch in diameter. The lower inch of the ileum was œdematous, and the crowded solitary glands were swollen and presented a sago-like appearance with a crimson background of extravasated blood. There were similar extravasations in the adjoining mesentery. The remainder of the intestine and other organs were normal. The intestinal appearances were explainable only in the theory of a small intussusception which had reduced itself.

**On the Nature of Curschmann's Spirals.**—These are the bodies in the sputa of asthmatics, and E. E. Laslett is of the opinion that some, if not all of them, are due to the same cause as are the casts of fibrinous bronchitis (Goodhart's theory). He reports the case of a woman aged twenty-six years and suffering from asthma. As many as a dozen Curschmann's spirals were coughed up in twenty-four hours. Associated with them were casts of the smaller bronchi. The spirals showed in some instances a division into two distinct branches at one end. The symptoms in Laslett's case were about half-way between asthma and plastic bronchitis. The forced inspiration of the patient, followed by prolonged and difficult expiration, suggested asthma, while the long duration of the coughing spells and the presence of casts in the sputa pointed to fibrinous rhinitis. It is generally believed that the spirals are due to a twisting movement given to a mass of mucus in one of the bronchial branches. Laslett believes that in reality they are casts of the smaller bronchial branches, similar in nature to the casts of a plastic bronchitis. In support of this view, he calls attention to the following points: (1) fibrinous casts frequently show spiral terminations; (2) these terminal spirals are practically identical in structure with the true Curschmann spirals, also present in the sputum; (3) the spirals, at least in this case, owe their peculiar structure largely to the arrangement of the great number of cells present; and (4) some of the spirals terminate in two equal branches of smaller diameter than the parent stem. This fact alone makes it difficult or impossible to believe that these structures are formed by a spiral movement.

*British Medical Journal, November* 7, 1903.

**The Treatment of Eclampsia by Hypodermic Injections of Morphine.**—W. Boxer Mayne reports two cases of eclampsia in which the hypodermic injection of morphine promptly checked the convulsions. The first patient was a woman aged thirty-two years. One injection of morphine, gr. ½, croton oil, ♏ij, was given, and the recovery was uneventful. The second patient was a primipara aged twenty-three years. The physician was called to the patient when she was in a comatose condition following a fit. An injection of morphine sulphate, gr. ½ and strychnine, gr. $\frac{1}{30}$, was given. The patient was wrapped in a hot wet pack. Later calomel and a mixture of bromide and diuretics were given. Progress was uneventful.

**Puerperal Septicæmia Treated with Antistreptococcus Serum.**—W. J. Caie reports a case of puerperal septicæmia in which the improvement dated from the first dose of antistreptococcus serum. Each injection of serum was followed by a lowered temperature, though repeated injections were required to combat the septic process. The serum should be absolutely fresh and should be administered as soon as it is known that the case is septic. A delay of hours only, in using the serum may make all the difference in averting a fatal result. The high mortality of the disease warrants the use of drastic measures in the very early stages.

Richard Jones also reports a case. The patient was a woman aged thirty-one years. She was a multipara and was confined by a midwife. The following day she complained of headache with flushes and chills and pain throughout the body. The condition became steadily worse, and a week after the confinement the first injection of serum was given. In all, nine injections of serum were given. There were no cultivations made, but there is little doubt, so the writer believes, that the case was due to streptococcus pyogenes, producing streptomycosis. Of course puerperal infection may be independent of streptococci, but the combination of such symptoms as, rigors, high temperature, very rapid pulse and breathing,

sweats, and very rapid bodily waste, points without any doubt to streptococcus infection.

**Tuberculosis of the Nervous System.**—E. F. Trevelyan first discusses the various forms which the tuberculous infection may assume in the nervous system. These forms consist of tuberculosis of the dura mater, tuberculous meningitis in its more general and limited forms, tuberculous masses in the brain and cord, and a possible miliary tuberculosis of the brain itself. As to the limited meningitis, the author has nine cases in his series in which a localized thickening over a limited area of the cortex was noted; the most marked case was in a boy of seven years. Tuberculous masses in the brain are not infrequent. The relatively rare tuberculous tumors of the dura are nearly invariably multiple, and grow from its inner vascular surface in the posterior fossa or from the falx cerebelli. As to the mode of infection of the brain and meninges, it is admitted that a complete examination almost invariably reveals an older tuberculous focus somewhere in the body. The actual infecting focus may exceptionally be small and easily overlooked, and it is plain to see that the oldest lesion is not necessarily the infecting one. The route by which the bacilli travel from the infecting focus to the meninges or brain is far from being satisfactorily worked out. It is either by the blood or lymphatic vessels. It is strange that the lesions of the ordinary tuberculous meningitis should, as a rule, focus themselves about the middle cerebral artery and its branches, whereas tuberculous tumors are more frequently found in the distribution of the basilar and posterior cerebral arteries. The points of importance, according to the writer, in the examination of the spinal fluid are the presence of the tubercle bacillus and lymphocytes in the deposit, and the results of the inoculation test. Although the writer cites some remarkable recoveries from severe tuberculous meningitis, he declares that the prognosis must still be looked upon for practical purposes as hopeless.

*Deutsche medicinische Wochenschrift, October* 29, 1903.

**The Treatment of Constipation in Infants.**—Clamann treats constipation in infants by introducing a well-oiled soft-rubber catheter several inches into the rectum. If necessary it may then be moved in and out several times, but usually its mere presence is sufficient to excite active peristalsis. The method may be used for weeks, the only consideration being that the diet is suitable and the motor activity of the gut sufficient.

**Hemisystole and Bigeminal Pulsation.**—Riegel believes that the phenomenon described by v. Leyden as hemisystole is really due to a bigeminal pulsation. In v. Leyden's cases two rapidly successive systolic impulses at the apex were accompanied by two venous pulses but by but one arterial pulse. He therefore assumes that with the first apex beat both ventricles contract, while with the second only the right ventricle has an additional systole. The author considers that the condition is due to an interruption of the normal diastole by a premature and weak bigeminal systole, which, however, makes itself distinctly palpable at the apex, owing to the fact that it occurs when the heart has not yet had time to resume its natural relations. This frustrate systole is not sufficiently powerful to distend the arterial walls which at that moment are contracting as a result of the first systole, therefore no palpable second impulse occurs, though sphygmographic tracings sometimes show a slight secondary elevation. The phenomenon usually occurs after the administration of digitalis, the author has found that small doses of the drug favor its production just as much as the larger ones which v. Leyden mentions.

**The Morphology and Chemistry of Fatty Degeneration.**—Riffert attacks the standpoint of those who would explain the phenomena of fatty degeneration by chemical methods alone, and points out the fallacies that occur when pure chemistry is applied to biological problems. He denies that more than a slight portion of the fat in fatty degeneration arises from amounts previously present in the cell, and affirms that for the most part it represents an infiltration of fat into damaged cells. Fat occurs in the cells under two conditions, both of which are forms of infiltration. The one is a storing up of fat in the normal fat cells (and those of the liver?), the other a deposition of fat in diseased cells. This latter is equivalent to fatty degeneration, though not in its older sense. Chemical analysis has shown that the fat content of a kidney with marked fatty degeneration might be no greater than the normal amount. Chemical methods, however, take no account of the morphological differences existing in various parts of the organ, and an increased amount of fat present in the cells of the loops, for example, often occurs with a decrease in other portions of the tubule; indeed, degeneration of the entire tubule rarely takes place and even then not uniformly. Many of the results of the chemical experimenters have been derived from studies of animal organs, and are open to criticism on this account also, as pathological changes of this nature do not reach the same degree of intensity in animals as in man.

*Münchener medicinische Wochenschrift, October* 27, 1903.

**A Previously Unrecognized Action of the Rontgen Rays on the Animal Organism.**—Albert-Schönberg found that by exposing male rabbits to the Röntgen rays for a considerable length of time they lost the power of reproduction. Whether this loss is permanent or temporary has not yet been determined. The animals did not suffer in general health and their sexual appetite and power of copulation did not suffer any impairment. The impotence thus introduced is due to a primary necrospermia, which ultimately goes on to azoospermia. Eleven guinea-pigs and rabbits were exposed to the rays for periods varying from one hundred and ninety-five to twelve hundred and eighteen minutes during a space of from one to eleven days, and then kept in company with females for weeks or months. Although previously fruitful none of the females become pregnant, and autopsies of the males showed total absence of motile spermatozoa in the seminal vesicles.

**The Nature and Etiology of Granular Kidney and Its Treatment.**—Edel, in consequence of the benefit attending his system of graduated exercise in the treatment of cyclical albuminuria, was led to transfer the method to cases of well-developed chronic interstitial nephritis. In spite of the prevalent belief that muscular exertion increases the permeability of the renal epithelium for albumin, his cases were benefited by mountain climbing, and he explains the discrepancy by attributing it to the lack of differentiation of the periods of rest and exercise in examining the urine as ordinarily done. His observations on patients show that warmth and carbonic acid baths appreciably diminish the blood-pressure and the percentage of albumin. In many cases these effects may be prolonged by moderate exercise instead of rest. Rest in bed has somewhat the same effect, due apparently in part to its acting like a mild bath, since simply rest in the recumbent position is less effectual. Of about equal value is the inhalation of amyl nitrite. Mountain climbing produced a moderate rise in blood-pressure, but a well-marked drop in albumin excretion and a permanent improvement in the general condition of the patient. The author considers that the renal lesion depends on some anomaly of the vascular system, which is chiefly manifested by a narrowing of the vessels. This he ascribes, in many cases at least, to a neurosis having its origin in neurasthenia as well as in the usual etiological factors of gout, alcoholism, lead-poisoning, and arteriosclerosis.

**The First Successful Ligation of the Hepatic Artery for Aneurysm.**—Kehr describes the first case in which this condition was treated by ligation of the hepatic artery, the patient making an uneventful recovery. The patient was a man of twenty-nine years, who had been suffering for several years with gall-bladder symptoms, the most characteristic feature of which was repeated severe hæmatemesis and anæmia. The diagnosis of hydrops of the gall-bladder, with duodenal ulcer and hepatic aneurysm, was made. On operation the gall-bladder was found greatly distended with grumous fluid and behind it a large pulsating tumor, recognized as an aneurysm of the hepatic artery, was felt. The gall-bladder was extirpated, and the hepatic artery, bile duct and portal vein were isolated in the hepato-duodenal ligament. The hepatic artery was then divided between double ligatures and the aneurysmal sac opened and cleared of clots. The patient made an uncomplicated recovery, and was discharged six weeks after operation. The author calls attention to the fact that while ligation of the hepatic artery in healthy animals produces death through necrosis of the liver, in such cases as this, in which the slow formation of the aneurysm allowed a collateral blood route to be formed, branches of the phrenic arteries take up the duty of nourishing the organ .

*Berliner klinische Wochenschrift, November* 2, 1903.

**The Temperature Course after Splenectomy.**—Moraczewski reports a series of analyses of the urine and fæces of a patient whose spleen had been excised seven months before and who was under treatment for pneumonia. Nothing especially worthy of note was observed except that both leucocytes and erythrocytes fluctuated considerably during the ten days the patient was examined, and that the phosphates and potassium salts in the urine diminished as the leucocytes increased, while the calcium salts accompanied the leucocytes in their rise.

**A Gastric Phenomenon Accompanying Migraine and Epilepsy.**—Mangelsdorf has found that the stomach of migraine patients undergoes a considerable increase in size

during the attack, the enlargement taking place in all directions. Further study of the subject has shown that epileptics are similarly affected, and that both classes of patients after a longer or shorter time acquire a permanent state of gastric atony. The effect on the stomach is supposed to be due to some central nervous stimulus, as obscure as the nature of the diseases themselves. Four hundred and nine migraine patients examined by the author showed the symptom in every case but one, that of a fourteen-year old girl who had had but few attacks.

*French and Italian Journals.*

**The Treatment of Pleurisy.**—J. E. Dubé says that all cases of pleurisy which are not secondary to heart disease, to cancer of the lungs, or infectious disease, should be considered as tuberculous. The patient should, therefore, not be weakened by excessive purging, by diuretics, or diaphoretics. He should be kept in bed, and well nourished. Intense pain should be relieved by morphine, or by wet cupping. Antipyretics should be given if necessary, and diuretics and laxatives in moderation. Digitalis and caffeine may be administered. Thoracentesis is not a radical cure, but it is useful where there is considerable fluid and where asphyxia or syncope are threatened.—*L'Union Médicale du Canada*, October, 1903.

**Suprarenal Extract in Gastroenteric Atony.**—Giuseppe Marricardi has made a study of the action of Vassali's preparation of the medullary substance of the suprarenal capsule of oxen and reaches the conclusion that it is beneficial in atony of the stomach by reason of its myokinetic properties. It is less markedly useful in intestinal atony if given by the mouth, but is efficacious when given in enemata, and is rapidly purgative. From 30 to 100 drops should be used in the enema. In gastric troubles the suprarenal extract arrests fermentation, and tends to increased body weight. In cases of intestinal occlusion of nervous causation, the remedy administered in an enema may be of diagnostic value.—*La Riforma Medica*, October 14, 1903.

**Variations in the Weight of Children Sent to the Mountains for Treatment.**—A writer, non-medical, records his observations of the effect of mountain-air treatment on children, and concludes that of two children of the same sex and age, the one to derive the most benefit is always the one of least weight. Of two children weighing the same at the start, the one to get the most benefit will be the oldest, and the female. Of a boy and a girl under the same relative conditions as to their body weight compared to their age, if the age of the girl is three-quarters less than that of the boy. the boy will show the greater gain. If the age of the girl equals three-quarters of that of the boy, both will derive equal benefit. If the age of the girl is more than three-quarters that of the boy, she will be the one to gain the most.—*Le Bulletin Médical*, October 17, 1903.

**Anomalies of the Lingual Artery from the Operative Point of View.**—M. Mériel and M. Florence conclude from their observations: (1) That Pirogoff's triangle is of such variable dimensions as to be sometimes practically non-existent. (2) That in consequence it is better to give up trying to utilize it, and to look for the artery in the posterior triangle, called the triangle of Béclard. (3) In this latter triangle the artery will usually be found parallel with and near the side of the hyoid bone. If necessary, it can be looked for near the original trunk. Of course, ligature of the lingual artery will usually be done according to Whitehead's recommendation, on the buccal plane. Nevertheless in some cases, as when the tongue is removed by the subhyoid route, or a large cancer is to be extirpated according to Poirier's method, it may be useful to ligate the lingual artery in the manner described.—*Bulletins et Mémoires de la Société Anatomique de Paris*, July, 1903.

**Surgical Intervention in Diseases of the Stomach.**—Andrea Ceccherelli concludes from a series of observations of cases operated on for stenosis due to inflammatory processes, syphilis, tuberculosis and cicatricis: (1) The results are better the earlier the intervention. (2) General conditions improve markedly, especially after gastroenterostomy. (3) The stomach returns to its normal conditions after this operation, but not quite so well after pyloroplasty. (4) Motility returns more completely after gastroenterostomy. (5) Emptying of the stomach is hastened for a few days after operation, but gradually returns to normal. (6) The hydrochloric secretion becomes almost normal. (7) The new pylorus holds its contents. (8) In gastroenterostomy a reflex of bile is observed, but not in pyloroplasty. (9) Gastroenterostomy is the operation to be chosen in cases of benign stenosis. because there may be relapses after pyloroplasty.—*Gazzetta Medica Lombarda*, October 18, 1903.

**The Treatment of Affections of the Heart by Exercise and Motion.**—Fernaud Lagrange states that in Stockholm heart disease suggests medical gymnastics as treatment, just as in France it suggests digitalis. The author observed patients thus treated for a long while and saw many who reached an advanced stage of asystole daily lose more and more of their cyanosed appearance, dyspnœa and œdema, while their pulse became stronger and more regular, and the urine became clear and abundant. The patients themselves are so convinced of the value of the treatment that they hasten to take it up again at the first symptom of circulatory disturbance. It is matter for surprise that treatment based on reasoning so rational and so physiological, and supported by so many successful results, should not have been more enthusiastically adopted in other countries.—*Journal de Médecine de Paris*, October 25, 1903.

**Anæmia in Children.**—Among other causes of anæmia G. Carrière mentions overfeeding. An excess of alimentation causes gastric stasis and intestinal autointoxication, and resorption of the intestinal poisons destroy the red globules and cause anæmia. The author has observed three cases in which overfed children were restored to health simply by moderating their diet, without any other treatment. Anæmia in children may also be caused by chilling, which is not surprising, as the writer has proved by experimentation that cold induces a marked destruction of red corpuscles. Overtaxing the physical or mental strength is another frequent cause of anæmia. The author recommends the usual hygienic measures, and in the way of medication praises the cacodylate of sodium. It is best to use it for a while, beginning with three-drop doses twice a day and increasing a drop at a dose until ten drops are taken twice daily. This may be kept up for eight days, diminished drop by drop until the primary dosage is reached, and a rest of ten days is then taken. Iron treatment may be instituted later.—*Le Nord Médical*, October 15, 1903.

**Treatment of Cerebral Apoplexy.**—G. Paquin protests against blood-letting in this affection except in cases of intense congestion. The difficulty consists in making a positive diagnosis, as to whether thec ondition is due to cerebral softening, to a simple neurosis, to an embolus, congestion, or hemorrhage. Bleeding in the case of softening would be disastrous. Moreover, even in the case of congestion various authorities have demonstrated that bleeding is inefficaceous; that the more blood is lost, the stronger fuller, and harder the pulse becomes, while the heart beats are violent and irregular. The author reports three cases which he treated by placing the patients in a semi-sitting posture, applying ice to the head, mustard plasters to the epigastrium, thighs, and legs, and hot water bottles to the feet. A purgative water was given in large amount, and as soon as the symptoms improved, a little bromide of potassium. Milk and raw eggs were the first nourishment allowed. Strychnine and iodide of potassium were given later. Recovery was very satisfactory.—*Le Bulletin Médical de Québec*, October, 1903.

**Subdiaphragmatic Massage of the Heart.**—M. Bourcart describes his experiments on dogs, and reaches the conclusion that in cases of accident, due to chloroform, and in case of death by strangulation, massage of the heart through the diaphragm (the technique of which he describes in full) will often restore the patient to life. The danger is much less than when the thorax is opened. Subdiaphragmatic massage can be performed while artificial respiration is being applied, the rhythmical pressure to the diaphragm aiding rather than hindering the process. The patient should be placed in a position to relax the diaphragm, by slightly elevating the pelvis, and laparotomy having been performed, the hand is introduced and the heart seized through the diaphragm. Care must be taken not to compress the coronary arteries, nor the bronchi, while the massage is being applied, injections of normal salt solutions or of adrenalin hydrochlorate, 1 to 10,000 may be given.—*Revue Médicale de la Suisse Romande*, October 20, 1903.

**The Cytological Study of Inflammatory Exudates from Serous Membranes.**—Angelo Signorelli concludes from his researches: (1) In inflammations of the serous membranes there is a general and a local cellular reaction. (2) The general reaction is shown by polynucleosis. (3) Lymphocytosis is the expression of a local reaction on the part of the organs and lymphoid tissues of the serous membranes and subjacent tissues, and occurs in all subacute and chronic processes, and in acute processes after the inflammatory period has subsided. (4) There is a true and a false lymphocytosis, the latter being due to newly formed or embryonal tissue which resemble lymphocytes. (5) In some processes, as tuberculosis for instance, the lymphocytosis may be in part accounted for by a special irritative action of the toxins on the locally inflamed tissues. (6) A definite cytological process exists for every inflammatory irritation of a serous membrane.—*Il Policlinico*, October, 1903.

# Book Reviews.

Diseases of the Nose and Throat. By Charles Huntoon Knight, A.M., M.D., Professor of Laryngology, Cornell University Medical College. Fellow New York Academy of Medicine, of the American Laryngological Association, etc. Philadelphia: P. Blakiston's Son & Co., 1903.

The author states in his preface that the matter here presented has formed for some years the basis of his lectures to students, and it is for them that he particularly writes. He includes only the essentials of anatomy, leaving its details to special textbooks. He regards many questions in rhinology and laryngology as still unanswered. Such questions are the action of the vocal bands, theories of intranasal pathology, laryngeal innervation, etc. Consequently he presents his views from the standpoint of a writer who has, indeed, settled convictions, but who is open to the influence of new testimony.

The book is divided into twenty-four chapters and covers practically everything a student needs to know. One cannot read it without being convinced that it is the outcome of an exhaustive study of the literature of the subject and alike the record of a long clinical experience. Its tone is eminently conservative, yet an acquaintance is manifested with the very latest operative procedures and therapeutic measures. The author has a courteous consideration for the opinions of others, but is very definite in his reasoning for the course he advises with reference to various clinical problems. He has carried the art of condensation to a remarkable degree without the sacrifice of either clearness or good rhetoric. His teaching is abreast of the day, is safe and stimulating. His pages are not merely academic expositions of nose and throat maladies, but vividly present them in such a way as can come only from careful study and long clinical experience. The book has an attractive dress and a good index.

Manual of Practical Anatomy. By D. J. Cunningham, M.D. (Edin. and Dublin), D.Sc., LL.D., D.C.L. (Oxon.). Third Edition, 12mo, pp. 1166. Philadelphia: J. B. Lippincott Company, 1903.

The second edition of this excellent anatomical guide contains several new and interesting features, chief among which are the illustrations, which are of exceptional artistic finish, and the exposition of the new doctrines concerning the relative changes of the viscera dependent on different attitudes in the living body. The descriptions are admirable in their perspicuity and terseness, and are well calculated to appeal to the earnest student, whose aim is to get the most out of his reading in books of convenient size. The manual is well calculated to supplement the classic textbook in anatomy which has made its author the leading teacher in his branch.

A Textbook of the Diseases of Women. By Thomas A. Ashby, M.D. Professor of Diseases of Women in the University of Maryland; Fellow of the American Gynecological Society; ex-President of the Medical and Chirurgical Faculty of Maryland and of the Baltimore Gynecological and Obstetrical Society; Honorary Member of the Medical Society of the District of Columbia; Consulting Gynecologist to the Mt. Hope Asylum, to St. Agnes Hospital and to the Hebrew Hospital of Baltimore, etc. With 233 Illustrations. Baltimore: Williams & Wilkins Company, 1903.

This work of 650 pages is intended for the use of medical students and practitioners of medicine. A short historical sketch of gynecology introduces the text. The anatomy of the external and internal ofgans of generation and the development of the reproductive organs are described in detail, and there are profuse illustrations. Physical diagnosis is then taken up in a thorough manner, and the various methods of examination of the genital organs are carefully described. The management of gynecology, is considered from two standpoints—medical and surgical. The hygiene of menstruation, as well as its anomalies, is dwelt upon. Aseptic surgery, although treated rather briefly, is nevertheless sufficiently full and clear to impress the reader with its great importance. The writer has used the anatomical method in arranging his text, believing this to be the simplest and most direct way of dealing with the various subjects. From a consideration of the simplest phenomena, he leads up gradually to the more complex. Diseases and malformations of the external and internal genital organs are given a prominent place. Various operations upon the organs of the pelvis are described in order to give a practical knowledge of operative gynecology. These operations are fully illustrated. A chapter is devoted to peritontitis and cellulitis, while another takes up the diseases of the urethra, bladder, and ureters. The original value of the book is enhanced by 233 illustrations. There is a very good index. The arrangement of the text is clear and systematic, appealing to the reader at the first glance.

Nurses' Guide to Surgical Bandaging and Dressings. By Wm. Johnson Smith, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. Philadelphia: J. B. Lippincott Company; London: The Scientific Press, Limited.

This convenient little pocket reference book of 165 pages explains the modern scientific treatment of wounds, and gives instruction in dressing and bandaging. It is profusely illustrated, and is completed by an index.

Clean Milk. By S. D. Belcher, M.D. Research Worker in the Rockefeller Institute for Medical Research, Attached to the Research Laboratory of the Department of Health of the City of New York. With an Introduction by William Hallock Park, M.D., Professor of Bacteriology and Hygiene in the University and Bellevue Hospital Medical College, and Director of the Research Laboratory of the Department of Health of the City of New York. New York: The Hardy Publishing Company, 1903.

This attractive book deals with a subject of the greatest value to humanity. The author begins with the cow-yard and pasture, describing the relation of the yard and the pasture to the cleanliness of the herd. She tells how to improve the cow-yard. The cow barn is treated comprehensively. This chapter includes equipment, storage, ventilation, light and tuberculosis in cattle, and care of the barn, winter stabling, and cows' bedding and feeding. The question of the preservation and bottling of milk is carefully considered. The opportunity of the dealer and the duty of the consumer are discussed. This little book is a mine of information on the subject which it treats. It is profusely illustrated.

A Handbook of Obstetric Nursing, for Nurses, Students, and Mothers; Comprising the Course of Instruction in Obstetric Nursing Given to the Pupils of the Training School for Nurses Connected with the Woman's Hospital of Philadelphia. By Anna M. Fullerton, M.D., formerly Obstetrician, Gynecologist, and Surgeon to the Woman's Hospital of Philadelphia, Physician-in-charge and Superintendent of its Nurse School; and Clinical Professor of Gynecology in the Woman's Medical College of Pennsylvania; late Lecturer on Surgery and Operative Midwifery in the North India School of Medicine for Women. Sixth Revised Edition. Illustrated. Philadelphia: P. Blakiston's Son & Co., 1903.

The writer has brought a great deal of valuable information together in this little book He considers the pelvis with its possible deformities, pregnancy with its signs, management, and accidents. The duties of the nurse during labor and the care of the new-born infant are described. The book contains a variety of illustrations, and is qualified to prove useful to nurses, patients, and physicians.

The Exact Science of Health Based upon Life's Great Law. By Robert Walter, M.D. Vol. I—Principles. New York: Edgar S. Werner Publishing Company. London: Kegan Paul, Trench, Trübner & Co., Ltd., 1903.

The writer says in his preface that the title of this book is not intended to proclaim infallibility, but is meant to declare to the world at large a science of physiology and system of health which are based upon discoveries exactly analogous to those which have placed astronomy and chemistry in the category of the exact sciences. He compares life's great law with the law of gravitation. He dwells upon the instinct of self-preservation with which every particle of living matter is endowed. Among the subjects treated are Social and Scientific Paradoxes, Transmutation Fallacies, Vital Science in Its Relation to Philosophy, Causes and Occasions and Their Relations, Life's Secondary Laws, Sanatory Medicine, Its Truths and Errors, and Good Health; How to Regain and Maintain It.

The Practice of Medicine. A Textbook for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University; Physician to the Pennsylvania Hospital; Fellow of the College of Physicians of Philadelphia; Member of the Association of American Physicians, etc. Third Edition, thoroughly Revised and in Parts Rewritten. With 134 Illustrations, including Colored Plates. Philadelphia: P. Blakiston's Son & Co., 1903.

In the seven years that have passed since the first edition of this work saw the light it has made for itself an assured place in the literature of medicine comparable to that held by Niemeyer or Bristow a quarter of a century ago—and for the book itself little more remains to be said. In the present edition, the author tells us, the section dealing with the infectious diseases has been subjected to

special scrutiny and revision, the additions and alterations here being so numerous as to necessitate a resetting of this entire portion of the work. The sections dealing with pathology, symptomatology, and diagnosis are throughout classical in their completeness and accuracy of description, but we cannot always praise the writer's therapeutic recommendations; they are apt to be rather old-fashioned, the newer methods being more or less ignored. We can find no reference, for example, to the use of the salicylates or of creosote in pneumonia, yet these, the latter at least, have received the endorsement of some of the highest authorities in medicine in this country. We do not expect a writer to favor any plan of treatment which he may not believe in, but he should, in all fairness to his readers, at least mention therapeutic methods which are employed with satisfaction by a very large proportion of medical practitioners. However, this fault is apparent in only a few instances, and it is the one fly in the ointment, the only thing, indeed, that prevents us according to Dr. Tyson's book unstinted praise.

ADENOMYOME DES UTERUS. Von THOMAS S. CULLEN, Hülfsprofessor der Gynäkologie an der Johns Hopkins-Universität, gynäkologischem Assistenten am Johns Hopkins Hospital in Baltimore, Maryland, U. S. A. Mit 45 Abbildungen im Text. Berlin: August Hirschwald, 1903.

THIS is one of the works dedicated to Dr. Johannes Orth in celebration of his 25-year professional jubilee by his assistants, pupils, and friends. The little volume gives the results of the author's work on this subject in the Pathological Laboratory of the Johns Hopkins University, which is so justly noted for its rich material. Adenomyome is treated in its different varieties and locations. The text has 45 illustrations. The book will prove a valuable addition to the work on this subject already accomplished.

HYDROLOGIE. Par HENRI CAUSSE, Chargé du Cours l'Hydrologie à la Faculté de Médicine et de Pharmacie de Lyon. Paris: F. R. de Rudeval, 1903.

THE writer considers carefully the composition of potable water, and describes the process of the estimation of its constituents. He then considers the gases that may be dissolved in water. Another chapter is devoted to bacteriology. Next the contamination of water is discussed. Lastly, the subject of French mineral waters is treated. The name of the author speaks for the excellence of the work.

NOSE AND THROAT WORK FOR THE GENERAL PRACTITIONER. By GEORGE L. RICHARDS, M.D., Fall River, Mass. Fellow American Laryngological, Rhinological, and Otological Association, etc. New York: International Journal of Surgery Co., 1903.

THIS manual is made up of a series of papers recently published in the *Journal of Surgery*. Intended, as it is, for the general practitioner, the author has followed conservative lines and has omitted historical matters and those concerning which discussion is still in an unsettled state. Yet he has succeeded in clearly setting forth the main facts of laryngology and rhinology in a concise form. His statements are definite, and on disputed points he gives the convictions derived from his personal experience, which has been large. Such books can rarely state anything new but to tell an old story in an attractive way, and to stimulate the reader's thought in the telling is a faculty not possessed by all writers. The book is well printed, but we could wish for greater clearness in some of the illustrations.

THE PRINCIPLES AND PRACTICE OF HYDROTHERAPY. A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. Second Edition, revised and enlarged. By SIMON BARUCH, M.D., Professor of Hydrotherapeutics in the New York Post-Graduate Medical School and Hospital. Visiting Physician to the J. Hood Wright Memorial (Formerly Manhattan General) Hospital; Consulting Physician to the Montefiore Home for Chronic Invalids; Member of the New York Academy of Medicine; Formerly Gynecologist to the Northeastern Dispensary; Physician for Eye, Ear, and Throat to the Northwestern Dispensary of New York City; Physician and Surgeon to the New York Juvenile Asylum, and Chief of the Medical Staff of the Montefiore Home for Chronic Invalids. With Numerous illustrations. New York: William Wood & Company, 1903.

THE fact that a new edition of this work has been demanded within so few years is certainly fair evidence of the growing popularity of hydriatric procedures. This is due to the modern scientific methods in the profession, which demand remedies which will give results beyond dispute in place of the empirical method so often based on nothing but tradition.

At first sight the author's claims for so many beneficial results from the use of water would seem extravagant did we not recollect that not only water, but heat, cold, mechanical, and chemical irritation are included means, all of which, in turn, are graduated by the length of each procedure and the differences in application. The work follows the main lines of the first edition in being primarily intended for the general practitioner, with demonstrations of methods which can be obtained in any household, along with the more accurately adapted technique which should be given in properly equipped institutions.

The newer portions include the latest points on physiology such as would have a bearing on the subject, and a very interesting discussion of the phenomena of reaction. An entirely new chapter on the hydrotherapy of mental diseases has been added, while the now unnecessary plea for the use of water has been dropped. Throughout the book the author has given reasons for all methods employed and has placed them on a rational basis, while his long experience has enabled him to offer a perfected technique such as would be best adapted to special conditions, together with the variations likely to be needed in individualizing their clinical application.

The addition of clinical histories serves to elucidate the more general descriptions in the text, and affords convincing evidence of the value of properly applied hydrotherapy.

The work, in short, is indispensable to all therapeutists who would work scientifically and effectively in the treatment of acute and chronic disease. It is the best work of its kind in the English language, practical, convincing, and written by an authority on the subject whose experience extends over a third of a century.

CLINICAL EXAMINATION OF THE URINE AND URINARY DIAGNOSIS. By J. BERGEN OGDEN, M.D., Late Instructor in Chemistry, Harvard Medical School; Assistant in Clinical Pathology, Boston City Hospital. Second Edition. Philadelphia, New York, and London: W. B. Saunders & Co., 1903.

THIS work will meet the most exacting demands of the physician, and will be found preëminently useful just where most books of the kind fail, *i.e.* in presenting with sufficient fulness the clinical significance of the changes found in the urine. The practical value of a guide to urinary analysis is usually well shown in the judgment displayed by the author in the description of the methods of detecting albumin and sugar, and when this test is applied in the present instance the book is not found wanting. Only the most reliable tests and methods are described, and that very lucidly and minutely. We note with some surprise that so little is said concerning the filtration of the urine: a few specific directions, with, perhaps, a caution against certain methods of clarification, would surely not have been amiss. This edition has been thoroughly revised, particularly in regard to the determinations of urea, uric acid, and total nitrogen; and cryoscopy and $\beta$-oxybutyric acid have also received attention.

PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST. By RICHARD C. CABOT, M.D., Physician to Out-patients, Massachusetts General Hospital; Assistant in Clinical Medicine, Harvard Medical School. Second Revised Edition. With One hundred and forty-seven Illustrations. New York: William Wood & Company, 1903.

THIS new edition of Dr. Cabot's work shows a few changes, but is practically the same as its predecessor. Among the additions we note the descriptions of the newer instruments such as are used in the measurement of arterial pressure. The author points out how useful these may prove in the records of cases of heart, kidney, and suprarenal diseases, intracranial hemorrhage and surgical shock.

The work is an eminently satisfactory one, and is especially adapted to students. Many of the errors which have been handed down in the smaller works have been eliminated in the volume, thus making it a much safer book from which a student may learn. The illustrations are numerous and the diagrams very helpful.

DAS TRACHOM ALS VOLKS- UND HEERESKRANKHEIT. Von Dr. J. BOLDT, Oberstabsarzt und Regimentsarzt des 9. Westpreussischen Infanterie-Regiments No. 176. Berlin: August Hirschwald, 1903.

THE author of this work presents a most careful consideration of the subject. The volume is one of 240 pages. The history of trachoma is given from the date of the writing of the papyrus of Eber, 1550 B. C., to the present time, and all the notable epidemics of trachoma are mentioned.

The second part takes up the geographical distribution of trachoma, the consideration of which occupies sixty pages. The symptoms and course of the disease are next described in an exhaustive manner. This is followed by a consideration of the etiology, to which thirty-two pages are devoted. The diagnosis, treatment, and prophylaxis of trachoma are then taken up and discussed in a manner equally exhaustive. To the bibliography ten pages are devoted.

The work is not illustrated. However, it is one of value to all ophthalmologists, since it presents all that is known of trachoma up to the present time.

SECTION ON MEDICINE.

*Stated Meeting, Held October 20, 1903.*

LEWIS A. CONNER, M.D., CHAIRMAN.

**Clinical Observations on the Late Effects of Typhoid Fever on the Heart and Vessels.**—Dr. WILLIAM S. THAYER of Baltimore was the author of this paper. He said that the infrequency of endocarditis as a complication of typhoid fever was well known, yet three cases had been observed in one hundred autopsies at the Johns Hopkins Hospital. That the cardiac lesions, as such, might account for sudden collapse could scarcely be doubted. The not infrequent arterial thromboses, notably in the vessels of the extremities and of the brain, which were probably the result of local infections of the vessel walls in most cases, needed only to be mentioned. The relation of acute infections to development of atheroma of the aorta and of arteriosclerotic changes generally had not received sufficient attention in this country. There was much which suggested that many acute infectious diseases, including typhoid fever, played an important part in the etiology of arteriosclerosis. Some observers believed that after acute rheumatism typhoid fever was the infectious disease most frequently resulting in changes in the heart and vessels. Out of fifteen patients between five and forty-eight years of age, which Landousi followed for nine years, there were three with evidences of cardiac disturbances. These three persons, five, three, and two years after typhoid fever, showed sudden hypertrophy and cardiac irritability. The angiocardiac lesions were important to recognize, not so much because of the prognostic reserve that they demanded during the course of the disease itself, as for what they imposed upon us for the future. Dr. Thayer said he had sent out about 1,400 letters with the object of inquiring into the condition of persons who had been in the Johns Hopkins Hospital with typhoid fever. The periods elapsed since their discharge ranged from one month to thirteen years. Out of this number he succeeded in having 182 appear for examination. Their ages ranged from three to sixty-nine years. Of these persons, 110, or 60.4 per cent., had a pulse rate between 60 and 90, and 16, or 8.7 per cent., had a pulse rate of 110. There was an irregular pulse in 13 cases. In 164 of the patients the blood-pressure was taken with the Riva-Rocci instrument. In order to rule out the confusion commonly arising from a full vessel the blood was milked out of the arteries and veins with two fingers, while with the third finger an attempt was made to roll the empty vessel under the finger. Over 50 per cent. of persons of twenty years of age in this group showed palpable radial arteries. Great care was taken to inquire into the occurrence of other disease since they had left the hospital. The rapid pulse in many of these persons was probably due to nervousness. Looking over the records of the hospital it was found that out of these 182 cases the palpability of the radial arteries had only been noted in 48 instances during their stay in the hospital. Dr. Thayer then made 276 estimations of the blood-pressure upon persons who were all presumably healthy individuals. The averages thus obtained showed a distinct and uniformly lower blood-pressure than in the old typhoid cases. So far as possible the observations were made under the same conditions in both series. Among the old typhoid cases there were 53 in which the blood-pressure was above 160 mm., and this list comprised 50 per cent. of those under thirty years of age. Of these 53 cases there were only 17 in which there was a history of alcoholism. The next step was to elminiate from the list those cases in which there was a history of pneumonia, erysipelas, smallpox, syphilis, and alcoholism. The average blood-pressure was 2 mm. less than in the uncorrected list. During the last few months he had made a series of examinations to determine the palpability of the radial and temporal arteries in 426 persons, not hospital patients. This gave a percentage of 17.6 of palpability of the arteries as compared with 46.8 per cent. in the old typhoids. The distance of the apex of the heart from the median line was next determined in 180 cases between the ages of twenty and fifty, and the average distance was found to be 9.1 cm. In 102 of the cases this distance, on admission to the hospital, averaged 8.7 cm. It should be remembered that most of these examinations were made while the typhoid was at its height. In 181 cases examined months or years after convalescence, cardiac murmurs were noted in 84, or 46.8 per cent. The majority of the murmurs were soft systolic ones with the maximum intensity in the aortic or pulmonic area. In 82 out of the 182 cases examined a reduplication of the second sound was made out, in all but one instance limited to the base at the pulmonic area. In 10 cases the reduplication was heard throughout the entire cycle. The blood-pressure in these cases was slightly below the general average. In the cases exhibiting accentuation of the heart sounds the pulmonic second sound was accentuated in 50.9, and the aortic in 43.4 per cent. Of the 182 cases there were 7 of more or less marked cardiac hypertrophy with valvular lesions, 5 mitral and 2 aortic, in which the history pointed to the typhoid fever as the only etiological factor.

The speaker said that this research seemed to indicate that these old typhoid cases were materially older, from the point of view of their hearts and arteries, and the fact tended to support the view that typhoid fever was a disease which was the primary cause of a fair number of cases of cardiac hypertrophy and dilatation occurring rather early in life, and without any history pointing to any other etiological factor.

Dr. FRANCIS P. KINNICUTT said that it was not uncommon for physicians to be puzzled by certain cardiovascular cases occurring in the early decades of life, and if these observations of Dr. Thayer were confirmed by further investigation, they would afford us a new and interesting explanation of these hitherto perplexing cases.

Dr. MORRIS MANGES said that if the paper did nothing more than explain the occurrence of arteriosclerosis in persons of twenty or twenty-five years of age, it would prove of great value to the profession. He met with many such cases in hospital practice, and he knew that many of the patients had had neither acute articular rheumatism nor typhoid fever. It was not improbable that any of the acute infectious diseases might give rise to these cardiovascular changes, a broader view which, he thought, might prove to be more in accordance with the facts. It seemed very strange that this original research had not been made before. The conditions were so vastly different during the course of typhoid fever and in health that he was doubtful if it was right to compare some of the observations as had been done in the paper, but the position taken by the author was sufficiently strong even without these doubtful figures.

Dr. ALEXANDER LAMBERT said that all the little pieces going to make up this research fitted so nicely into one another that, without any striking differences, they nevertheless furnished, when combined into one harmonious whole, a very convincing argument in favor of the correctness of the author's position. He would like to know whether the hospital records showed that these patients had suffered from nephritis. It was undoubtedly true that it usually took a year for a person to get over the effect of an attack of typhoid fever.

Dr. THAYER said that he did not lay any great stress upon the measurements of the distance of the apex of the heart from the median line during the typhoid fever and afterward. The measurements of the heart during typhoid fever were generally distinctly larger than after

recovery, and, hence, he expected the differences, if any, would be against the line along which he was working. It was undoubtedly true that other acute infections acted similarly to typhoid fever. In studying carefully the aorta in typhoid cases he had been impressed with the frequency with which large atheromatous plaques were found in these cases. He felt that, in this country, too much stress had been laid upon alcoholism, and too little upon the acute infections as causes of arteriosclerosis.

**Sequelæ of Typhoid Fever in the Nervous System.**—Dr. PEARCE BAILEY read this paper. He said that, according to his experience, while typhoid fever might be, as it was sometimes called, "the nervous fever," it was certainly not the neurologist's disease. It had been shown that lesions of the spinal cord, chiefly of the motor cells of the anterior horns and the spinal ganglia, were found quite commonly after typhoid fever. It was probable that the spinal paraplegias were due, in large part, to embolism and thrombosis It was probable that neuritis of typhoid fever arose from infection or from pressure. Cerebrospinal pressure was regularly increased during typhoid, but this disease also affected the peripheral nervous system. The poison attacked acutely, but rarely with sufficient violence to produce definite focal symptoms. Typhoid fever furnished abundant evidence of general and serious involvement of the whole nervous system, but it was exceptional for any one part to be singled out. In typhoid fever, spinal affections and peripheral nerve affections seemed to go together. The multiple involvement of peripheral and separated nerves was not usually seen in any other infectious disease. Aside from meningitis, hemiplegia was the most frequent brain complication of typhoid fever. It occurred most commonly during or after the third week. It was more frequent on the right side than on the left, and hence, was often associated with aphasia. The hemiplegias usually involved both the face and the extremity of the affected side, and did not seem to exert an unfavorable influence on the course of the typhoid, or prove fatal. Neuritis was by far the commonest organic sequela of typhoid fever in the nervous system. Pain was very prominent, and it often followed the distribution of individual spinal nerves without appreciable loss of power in the muscles supplied by the nerves. It was probable that these affections represented slight inflammatory rather than trophic processes in the nerves. Of the more pronounced nerve inflammations, the most frequent were those of the ulnar and peroneal nerves. Curiously enough the musculospiral nerve, the one usually so susceptible, was very rarely affected in typhoid fever. Inflammations of two or three nerves together were much more common than ordinary multiple neuritis; he could recall no case of multiple neuritis after typhoid fever, and found none reported in the recent literature. Ptosis and paralysis of the external recti had been frequently observed. Interference with the recurrent laryngeal nerve was particularly frequent. In a previous study he had collected two cases of Landry's paralysis following typhoid fever. The typhoid spine was originally supposed to be due to periarthritis of the dorsolumbar region. It was quite commonly associated with neurotic symptoms. Of the chronic degenerative diseases of the nervous system, multiple sclerosis was the only one in which there was any plain relation between it and typhoid fever.

Dr. JOSEPH COLLINS said that he too had found nervous diseases rather infrequent following typhoid fever, especially when viewed from the standpoint taken by the reader of the paper. However, when viewed from another standpoint, he felt that typhoid fever was a real factor in the causation of many nervous diseases. That point of view was from the vascular changes this disease produced in the nervous system. He was disposed to think that the only diseases of the nervous system which were directly dependent upon typhoid fever were arteriosclerosis and disseminated sclerosis. He had noted that, at the period of life when arteriosclerosis was looked upon as a natural accompaniment, typhoid fever did not call out this change. He regretted that more had not been said of the functional conditions following typhoid fever. He saw a good many cases of the depressed type of neurasthenia following typhoid fever. Some were due to arterial degeneration, but many to the overwhelming of the sympathetic system by the toxic products. Some of the cases referred to by Mitchell as typhoid spine bore a close resemblance to ordinary traumatic neurasthenia. He saw many cases which were diagnosticated as subacute myelitis, but he believed were, in most instances, really syphilitic spinal paralysis, and these were very commonly preceded a short time by an attack of typhoid fever.

Dr. WALTER MENDELSON said that in nearly all cases of typhoid fever the general practitioner was apt to see some affections which impaired the functions of the brain. We were, perhaps, not always justified in calling them neurasthenic. Cases of insanity occurred occasionally as a sequela of typhoid fever.

Dr. J. RAMSAY HUNT said that he had seen very few cases of the nervous sequelæ of typhoid fever. One of them was a case of multiple neuritis, and he mentioned it in order to throw out the suggestion that cases of this kind might very possibly be really alcoholic, and arise from the very free use of alcohol during the typhoid fever and while the patient was greatly exhausted. Cranial nerve palsy following typhoid fever was quite rare, and it was quite difficult to say whether these palsies were of peripheral or nuclear origin. Cases of pseudomeningitis occurred in the course of typhoid fever. In these cases there were no evidences of meningitis on gross examination, but histological examination showed very slight round-cell infiltration of the pia along the septum. Such cases suggested a slight anatomical basis for many cases of so-called functional nervous affections following typhoid.

Dr. W. L. BANER said that a distressing minor affection frequently following typhoid fever was the occurrence of areas of anæsthesia, which persisted for months or years.

Dr. MANGES said that in a large typhoid service at the Mount Sinai Hospital nervous sequelæ were very rare. No mention had been made in the paper of one complication, tetanus. He had had one such case in which a complete picture of tetanus was present in the fourth week. It subsided in four days. A marked heightening of the reflexes was supposed to indicate a bad prognosis, and it was certainly true that increased patellar reflexes were common.

Dr. ALEXANDER LAMBERT mentioned a case of tetanus with typhoid that he had seen, and which had never before been reported. In that case there was fixation of the jaw and complete opisthotonos.

Dr. THAYER said that the paper and discussion had impressed him with the very great seriousness of an attack of typhoid fever, and this suggested the necessity for controlling this disease as was being done in the case of tuberculosis.

Dr. LEWIS A. CONNER said that about the only nervous sequela that he had encountered after typhoid fever was the peculiar lassitude and inability to resume work for many months after this disease. This seemed to be a very common condition.

Dr. Bailey, in closing the discussion, said that he had not gone into all the clinical details; his object was simply to bring out the point, that during the acute course of typhoid fever the whole nervous system, both central and peripheral, showed definite organic changes, which were usually more or less temporary. They were, nevertheless, just the kind of changes which predisposed to the development of functional nervous diseases, including hysteria and melancholia.

SECTION ON PEDIATRICS.

*Stated Meeting, Held October* 8, 1903.

HENRY HEIMAN, M.D., PRESIDENT.

**Gangrene of Toes in a New-born Infant.**—Dr. S. V. HAAS presented an infant, four weeks old, born by the aid of forceps after a tedious labor. The day after its birth the left lower extremity was noticed to be cyanotic up to the knee. After about one week a general eruption appeared, which was stated to resemble prickly heat. When ten days old there was an attack of enterocolitis. When first seen by the speaker, one week ago, the left foot was swollen and the great toe and last phalanx of the second toe were black and gangrenous, necessitating immediate amputation of the affected part. Enlarged glands could be felt in the neck, axilla, and groin. The case was presented for diagnosis.

Dr. MARTIN W. WARE said that he suspected the case was one of syphilis, because of the involvement of the bone. If only the soft parts had been involved he would be disposed to think that the condition was the result of embolism, originating in infection of the umbilicus.

Dr. SARA WELT-KAKELS said that she was interested because she now had under her care a child of twenty months with gangrene of the little finger of the right hand, and, in addition, an erythema nodosum. It was thought that originally there had been a spot of that kind on the little finger, and that it had become gangrenous as a result of the application of some strong lotion. In other respects the child appeared to be well.

Dr. L. E. LAFETRA said that he understood that in the child presented there was dry gangrene present at first, produced by embolism. He was far from being convinced that the disease was specific.

Dr. H. HEIMAN remarked that the disease being unilateral would also be against its being luetic. He would like to know whether the mother had received ergot during labor.

Dr. Haas said that the liver and spleen were apparently normal and the family history was negative. The urine had been examined with negative result. He had at first been inclined to look upon the case as possibly one of dermatitis exfoliativa neonatorum of Ritter. He did not think the patient had received ergot during parturition.

**The Hemorrhagic Diseases and Their Allies in the Light of Modern Pathology.**—Dr. F. L. WACHENHEIM read this paper. He said that the customary inclusion of the hemorrhagic diseases in the blood diseases was extremely unsatisfactory. Spontaneous hemorrhage was caused by the yielding of the intercellular cement of the vascular wall as a result of the impairment of nutrition. Authorities did not agree as to whether the malnutrition or the thrombosis was the prior condition. Degeneration of the vascular endothelium must follow deficient food supply or the presence of a poison in the blood. Experience had shown that these two factors were invariably combined. It should be borne in mind that toxins differed only from true foods in that they damaged the cells. Potassium chlorate was an excellent example of the class of poisons which destroyed the hæmoglobin; the nitrites acted in a similar manner. Apart from the hæmoglobin poisons, the blood poisons presented nothing distinctive. Recent investigation had shown the action of the toxins on the blood cells to be somewhat complicated. Snake poison might be regarded as a type of blood toxin. Obstructive jaundice presented certain features which were closely allied to those of hæmophilia. In icterus there was no evidence of special blood dissolution or hæmolysis. Agglutinins had been demonstrated in the blood in jaundice, and such formation of agglutinins we knew only occurred in the presence of toxæmia. The characteristic feature of hæmophilia was not so much spontaneous bleeding as deficient coagulation. The symptoms of scurvy closely resembled those of chronic mercurialism, and it was evident that this disease was due to a chemical poison. It was now generally accepted that scurvy was the result of an exclusive diet on certain articles of artificially prepared food. The speaker was of the opinion that scurvy and rachitis unquestionably belonged to the same group. He then passed in review the chemical blood poisons, non-infectious taxæmias and infectious toxæmias. The conclusion was reached, that spontaneous bleeding by itself formed a most unsatisfactory pathological basis for classification. Some observers looked upon scarlatina, rheumatism, and ordinary sepsis as only different forms of sepsis. Endocarditis frequently followed tonsillitis without any of the usual rheumatic manifestations. He had seen typical rheumatic endocarditis combined with chorea in children who had never presented appreciable joint symptoms, but only moderate soreness and tenderness. The relation between chorea, rheumatism, and endocarditis was now generally conceded to be direct and intimate. Purpura hemorrhagica represented a group of infectious diseases of the septic type.

**Etiology of Rickets.**—Dr. P. W. NATHAN presented this paper. He said that the essential part of the pathological process was defective calcification. Up to the present time no local condition had been found that could be considered the cause of this defective calcification, and hence we must feel for the explanation of the anomaly outside of the skeleton. While it was true that total absence of calcium chloride from the food of the infant, even though this food were otherwise suitable, would lead to the production of the lesions of rickets, such a process was artificial and did not represent what was clinically known as rickets. Mother's milk, cow's milk, and the usual infant foods contained calcium in sufficient, and sometimes in excessive, quantities. Zweifel had propounded the theory that a deficiency of hydrochloric acid, and the consequent faulty assimilation of calcium, explained the production of rickets. The evidence presented by him was very interesting, but was not altogether conclusive. Even if his experiments and his conclusions were accurate, the theory was necessarily false because the premises were false. He assumed that hydrochloric acid was deficient in infancy, although there was abundant evidence to the contrary. An excess of potassium chloride in the food no doubt increased the sodium chloride loss, but this only occurred so long as the sodium chloride was in excess in the economy. Zweifel himself was not able to produce a sodium chloride deficiency. Other experiments had shown that even in the severest cases of rachitis the assimilation of calcium went on normally. Dr. Nathan said that for a period of about eighteen months he had had under observation three infants, each about three months old. They were given monocalcic phosphate and sodium chloride, and were fed on condensed milk, but despite this the evidences of rickets were quite marked about the time they reached the age of seven months. So soon as the infants were given a more suitable food they improved. The author then kept records of a large series of cases, some treated by the internal administration of phosphorus, others by giving calcium phosphate, while over one hundred were treated without medicine. It was found that those receiving medication did not show any more improvement than those receiving no medicine. The exposition of the anomaly of metabolism by which rachitis was produced was reserved for a future communication.

---

**The Discovery of Radium.**—The analysis of pitchblende led to the discovery of two strongly radioactive substances: Polonium, so named after Mme. Curie's native country, and which was discovered by M. and Mme. Curie; and radium, which was found by them in collaboration with M. Bémont. It may be mentioned, by the way, that, though we have only heard of radium within the last few months, it was discovered as far back as 1898.—*Pall Mall Magazine.*

## NEW YORK COUNTY MEDICAL ASSOCIATION.

*Stated Meeting, Held October 19, 1903.*

ALEXANDER LAMBERT, M.D., PRESIDENT.

Dr. FREDERICK HOLME WIGGIN presented several specimens.

**Presentation of a Patient Five Years after Resection of Rectum and Sigmoid Flexure for Carcinoma.**—This was the first case. The patient had come to him with the diagnosis of hemorrhoids. On endeavoring to excise the gut, traction on the bowel caused the latter to give way. Laparotomy was performed, and revealed the fact that the disease extended up into the sigmoid flexure and involved also a portion of the descending colon and a mass of glands. A radical operation was done, and the descending colon was drained through the rectus muscle considerably above the umbilicus. The abdominal wound was closed, but the perineal one was left open. To his surprise she made an excellent recovery. He kept her under observation for eighteen months, and then lost track of her until very recently, when she was found to be in excellent condition. For the past few months there had been tenderness around the artificial anus and a discharge of pus. The patient was exhibited.

Drs. PARKER SYMS and J. RIDDLE GOFFE examined the patient. They reported that, so far as could be ascertained, there was no evidence of recurrence internally, and the induration about the artificial anus was apparently not a return of the growth. The result was certainly remarkable, and should be considered a cure.

Dr. ALEXANDER LAMBERT thought that the infiltration of the abdominal wall was due to infection rather than to a recurrence.

**Axillary Contents.**—The second specimen consisted of the contents of the axilla, removed in July from a lady who had been operated upon for carcinoma of the breast. There was no evidence of inflammation of the old scar.

**Loose Fibroids.**—These fibroids were found free in the peritoneal cavity, with no connection with the uterus. They had derived their nourishment from the mesentery.

**Fibroids Removed by Hysterectomy from a Case Presenting Unusual Symptoms.**—The patient had been very much prostrated at the time of coming under observation, and the uterus enlarged. Under hypodermic injections of ergot the uterus was quickly reduced in size, and then it was easy to discover the presence of a number of fibroids. There were grave mental symptoms present, and it was because of these that the operation was undertaken. The vaginal operation was done, but was found rather difficult. There was an unusual amount of bleeding from the vaginal wall. Following the operation the pulse was between 84 and 100, and the temperature varied from 99 to 100.4°F. The next morning she suffered from nausea and severe abdominal distention. Lavage of the stomach and saline infusion were employed, and by afternoon her condition was apparently decidedly improved. However, a few hours later she suddenly complained of severe pain about the heart, and exhibited great dyspnœa. Death occurred that evening, apparently from central thrombosis.

**Specimens of Appendicitis.**—Several specimens were shown. The first was from a man who had been suffering from severe cystitis, and who had suddenly begun to complain of pain in the region of one kidney. Appendicitis being suspected, laparotomy was performed, and this revealed a long, inflamed appendix, with two gangrenous spots, and a large concretion in one end of the appendix. Recovery was satisfactory. Another, and fatal, case occurred in a child who had complained only of a belly-ache.

Dr. LAMBERT said that the clinical picture presented by Dr. Wiggin's case of hysterectomy was that of sudden occlusion of one of the coronary arteries. It was probable, from the appearance of the veins, that a number of clots were situated around the field of operation, and that a portion of one of these had broken off and passed into the circulation. This seemed, at first thought, rather strange, but no less an authority than Professor Welch had made the statement, that while the lung was an excellent filter for clots from the right heart, nevertheless a number of small clots did pass into the general circulation by way of the left heart.

**Adenocarcinoma of Sigmoid.**—Dr. JAMES P. TUTTLE presented a fresh specimen of adenocarcinoma of the sigmoid flexure removed, a few hours previously, from a gentleman of about fifty years of age. The man had begun to suffer nine months ago alternately from diarrhœa and constipation. There was a history of a syphilitic infection twenty-eight years previously. A tumor was found between the bladder and sigmoid flexure. The patient improved under antisyphilitic treatment, and so nothing more was done for eight months. When seen by the speaker, two or three months later, deep examination with the proctoscope was practically negative. The man was kept under observation, and, under active antisyphilitic medication for five weeks, improved in general health, but the tumor did not diminish, and he continued to pass blood and mucus daily. A specimen was removed with forceps and examined, but no carcinomatous tissue could be found. Then an exploratory operation was done, and this adenocarcinoma removed. The tumor was situated within one inch of the descending colon in the sigmoid flexure, and almost completely obstructed the intestinal canal. The lesson from this case was obvious.

**Ectopic Gestation.**—Dr. J. RIDDLE GOFFE exhibited a specimen taken from a woman of thirty-four years, with a child of six months at the breast. She had menstruated regularly on September 4, and since October 8 there had been an irregular discharge of blood with three distinct attacks of severe abdominal pain. A diagnosis of unruptured ectopic gestation was made. A vaginal operation revealed a small ectopic gestation in the right tube, and a considerable quantity of fluid and clotted blood.

**Gangrenous Dermoid Cyst of the Ovary.**—Dr. PARKER SYMS presented a specimen removed ten days previously, from a girl of sixteen. The symptoms had begun very suddenly, and when first seen by him, on the third day of the illness, her pulse was 130 and temperature 100°F. A large tumor presented on the left side of the abdomen. From the sudden onset and the rapidity of the pulse, as compared with the temperature, the nature of the condition was suspected before opening the abdomen. Operation revealed a dermoid cyst of each ovary. The one on the left had a double twist in its pedicle which had produced gangrene of the cyst.

**President's Address: Physiological and Therapeutic Action of Alcohol.**—Dr. ALEXANDER LAMBERT delivered this address. He said that the common teaching in the past had been that alcohol, in moderate doses, was a heart and cerebral stimulant, that it was a food and that it possessed the power of restraining tissue waste. But modern research had modified these views somewhat. Alcohol in moderate doses had no effect on the heart itself in a healthy subject, either of stimulation or depression; in larger doses it was a decided cardiac depressant. Similarly, in moderate doses it caused no increase in the pulse rate. It had no direct action on the vascular wall or upon the arterial pressure in the doses mentioned. The flushing of the face seen after small or moderate doses took place before there was any change in the blood-pressure. This was evidently due to some action on the nervous system, although no direct effect of such small doses upon the vasomotor centers could be demonstrated experimentally. Dr. Richard C. Cabot of Boston had recently found in typhoid fever that therapeutic doses of alcohol had no effect upon the circulation. That alcohol was an indirect circulatory stimulant in cases of shock, and under other special conditions, was certainly true. Abel

said that alcohol was a moderate respiratory stimulant, and that increased heat dissipation was invariably associated therewith. He looked upon alcohol as an indirect stimulant of the respiratory center, an effect less marked in the human being than in the lower animals. Cabot, however, showed that alcohol had practically no action, as a respiratory stimulant, in human beings when diseased. Alcoholic fluids greatly increased the flow of gastric juice and its content of acid and the total solids. This occurred even when alcohol was absorbed from the intestine. Whiskey, sherry, brandy, and porter all acted in this way. Strong alcoholic beverages, such as whiskey and brandy, did not markedly retard salivary digestion. The inhibition of amylolytic digestion was out of all proportion to the alcoholic content, and was dependent upon certain volatile ingredients. The weaker the gastric juice, the greater the inhibitory action of a given amount of alcohol. The presence of a small amount of fusel oil tended rather to increase the action of the gastric juice. White wines, containing about 11 per of alcohol, when taken in small amounts, tended to increase digestion. Ale, lager beer, and porter, taken in small quantities, had no inhibitory influence on the gastric digestion, but in larger amounts they inhibited proteolysis, because of the comparatively large amount of extractive they contain. Under ordinary conditions there was not much chance for alcohol to reach the bowel because of its rapid absorption from the stomach. The acid clarets and white wines were more inhibitory than sherry, although the latter contained twice as much alcohol. Ginger beer often exerted as much inhibitory effect as a corresponding amount of lager beer or Bass' ale. It should be remembered that this inhibitory action of alcoholic fluids was usually temporary, owing to the very rapid absorption of the alcohol, and, as a result of such absorption, there followed an increased flow of gastric juice, so that one very nearly counteracted the other, and the ultimate effect on digestion was, if anything, favorable. Rosenthal believed that alcohol tended to disturb rather than aid intestinal absorption. This was true no doubt when toxic doses were taken, but was not true of small doses. The experiments of Atwater to determine its nutritive value were models of scientific accuracy and completeness. The importance of alcohol as a remedy and of alcohol as a food was never lost sight of by this investigator. The total income of hydrogen, oxygen, carbon, and nitrogen, as well as the outcome, was carefully determined, as was also the amount of heat generated, and the amount of work done. He found that the amount of alcohol given off from the body was about 1.9 per cent.; hence about 98 per cent. of the alcohol taken in moderate doses in health was oxidized within the body. The amount of carbon dioxide and of oxygen after the ingestion of alcohol was changed but little. It was found that when the diet contained no alcohol the total energy of the food burned in the body was practically identical with the energy given off from the body by heat and muscular work, *i.e.* about 522 calories. Nearly the same result was obtained when alcohol was included in the diet. The author concluded that the law of the conservation of energy obtained with the ordinary diet as with the alcoholic diet. Many recent experiments showed that alcohol always protected the body fat. Atwater concluded that the power of alcohol to protect the body tissue from consumption had been clearly demonstrated. In this way alcohol served the body as food. Alcohol appeared to exert at times a specific action as a drug. In small doses it seemed at times to have a tendency to increase the disintegration of proteids, an action which, although not conclusively proved, seemed to be very probable. This was the only justification for calling alcohol a proteid poison, and such action was exceptional, and the exact conditions under which it occurred could not now be defined. The opinion that alcohol was more rapidly oxidized in the body than other substances, such as carbohydrates, had not been proved experimentally. Atwater came to the conclusion that the diet with alcohol was slightly less economical than the ordinary diet, but that the difference was very slight. General observations and the results of practical tests on a large scale showed that alcoholic beverages were of doubtful value, and were often harmful in the case of those who were required to do much muscular work. Alcohol would lessen the sensation of fatigue by its action on the nervous system. Alcohol would enable a brief spurt to be made, but it would not sustain muscular action, and its use was followed by depression. All acts requiring nicety of adjustment were interfered with by even small quantities of alcohol, and this agent lowered the acuteness of the cerebral centers and interfered with clear and logical action of the mind. Alcohol, therefore, should no longer be considered a stimulant, but rather a narcotic. Its only really stimulant action was upon gastric digestion. Although alcohol had been proved at times to be a food, such action should be considered strictly medicinal, or, as Atwater had said, it should be employed when the user was unable, because of debility or disease, to obtain fitting nourishment from ordinary foods. It should be remembered that alcohol was still a useful remedy, and one that should be employed in medicine, but it should not be forgotten that it, like other drugs, was a poison.

## Therapeutic Hints.

**Syrup of Iodide of Iron.**—This should be given after meals and best not combined with other drugs according to M. D. Hoge, Jr. It is useful:

1. In the *early stage of phthisis* in drachm doses three times a day. It promotes secretions, acts to some extent as a diuretic, and the weight of the body is increased.

2. In the *dry, rasping coughs and colds* which have been unsuccessfully treated, with resulting constipation and locked-up secretions, ten to fifteen drops every four hours will soon relieve the congestion, and expectoration will be abundant.

3. In *amenorrhœa and dysmenorrhœa, in scrofulous women especially*, it has a most happy effect—the menstrual flow in cases of amenorrhœa often being quickly reëstablished; the dose is thirty drops three times daily.

4. In *anæmic patients suffering from rheumatic gout*, one drachm given with pure cod-liver oil, often proves of very great benefit.

5. *Pale strumous-looking children*, with enlarged cervical lymphatic nodules associated with chronic catarrh of the throat or enlarged tonsils, are much benefited by ten-drop doses after each meal. It here acts as an alterative, rapidly bringing about an absorption of the swollen lymphatics.

6. In *cases of delayed resolution following croupous pneumonia*, iodide of iron acts as a tonic and reconstructive.

7. In the *incontinence of urine of children* it has been highly recommended in doses of from twenty to thirty drops in water after each meal.

—*Virginia Medical Semi-Monthly.*

**Acne Simplex**—The most useful method of treatment in severe cases seems to be curettage of all lesions with a broad, sharp curette, covering a large area at one sitting. Of equal importance is the extraction of all comedones, and the opinion is advanced that if careful search, with a lens if necessary, is made for incipient comedones their extraction thus early will do much toward the prevention of future acne lesions. Massage, not according to any fixed rule of manipulation, but merely by gently pinching the skin of the affected area, is also considered of great value, and as a topical application sulphur in some form is acknowledged to be the most efficacious. Many argue strongly against the employment of unguents in any form, and suggest that in massaging finely powdered pumice-stone be used to keep the fingers from slipping. We

have recently seen very happy results from the substitution of sulphur for the powdered pumice. Laxative and general hygienic measures are of well-known and undoubted advantage.—*Annals of Gynecology and Pediatrics.*

**For Nasopharyngeal Irritation with Cough.—**

℞ Menthol ..... 0.20
Acidi borici ..... 4.00
Petrolati ..... 30.00

S. Insert a portion of the ointment as big as a bean into each side of the nose several times daily.

—*Journal de Médecine.*

**Tonsillitis.—**

℞ Carbolic acid ..... 1
Resorcin ..... 8
Spirit of menthol ..... 20
Glycerin ..... 30
Distilled water ..... 450

S. Gargle.

**Granular Pharyngitis.—**

℞ Iodi ..... 0.40
Potassii iodidi ..... 0.80
Syr. Menth. pipis ..... 50.00
Aquæ dest ..... 250.00

M. S. Gargle. If too irritating, add an equal quantity of water.—*Journal de Médecine.*

**Fissure of the Anus.**—Apply pure carbolic acid thoroughly, then alcohol, and pack with gauze.

**Hepatic Colic.—**

℞ Olive oil ..... 150 to 400
Cognac ..... 15
Yolk of egg ..... 2
Menthol ..... 0.5

M. Take in the morning, in two doses, 15 minutes apart. —CHAUFFARD in *Progrès Médical.*

**A Rational Aphrodisiac.**—Strychnine sulphate, 1 grain; phosphorus, pure, ½ grain; atropine sulphate, ¼ grain; resin cannabis, 2½ grains. Make 100 pills, and give one or two from three to six times a day as required. When once an effect is produced they should be given less frequently.

—W. C. ABBOTT, in *Texas Courier of Medicine.*

**Dandruff.—**

℞ Resorcini ..... ℥i
Tannoformi ..... ℥i
Acidi salicylici ..... gr. v

Dissolve in

Aquæ ..... ℥i
Spir. vini rect ..... ℥iii

M. Filter. S. Apply to scalp once daily.

**To Make an Emulsion.**—The physician can secure in his office a sufficiently permanent emulsion by shaking oil in a clean bottle until the inner surface is well oiled. Then add alternately powdered acacia, water, and oil, shaking after each addition.

**Injection in Syphilis.—**

℞ Hydrarg biniodidi ..... gr. iss
Potassii iodidi ..... gr. ix
Sodii phos ..... gr. xv
Aq. dest ..... ℥ii
Decinormal saline sol ..... ℥ii

M. et ft. solutio. S. Sixteen drops by hypodermic injection daily. —ANTHONY.

**How to Administer Anæsthetics.—**

1. Don't give chloroform when there is degenerative disease of the myocardium, or when there is a decided fall in the blood-pressure.

2. Don't administer ether where nephritic trouble exists, or when there is any abnormality, acute or chronic, of the respiratory organs.

3. Don't give any anæsthetic until a thorough examination of the heart, lungs, and kidneys has been made.

4. Don't give enough of an anæsthetic to produce blood saturation. Give only sufficient to maintain surgical anæsthesia.

5. Don't give any agent in the heart depression incident to anæsthesia which lowers blood-pressure, but rather those which increase vascular tonus.

6. Don't watch the surgical operation, but give your undivided attention to your patient.

7. Don't fail to remember that every anæsthetic is dangerous and should not be administered except with caution and intelligence.

8. Don't think that accidents will not occur to you, but be prepared to meet any emergency that may arise, and be certain to have everything in readiness for that purpose. It is better to be prepared and not have an accident than to have an accident and not be prepared.

9. Don't fail to bear in mind that as an anæsthetizer you have entrusted to your care a human life, and that it is your duty carefully to guard its interests in every available way.

—E. L. MARÉCHAL, in the *Mobile Medical and Surgical Journal.*

## New Instruments.

### A NEW FORM OF INSUFFLATOR.

BY SAYER HASBROUCK, M.D.,
PROVIDENCE, R. I.

THE history of medicine shows that the therapeutic value of medicated powders has always been recognized, and the only drawback to their use has been the lack of a satisfactory appliance for their application. The fact that so many attempts have been made to supply this need is my excuse for describing one that so far has proven satisfactory, both to myself and my friends, who are now using it daily. Simple in construction, still it seems to overcome the many objections and faults of those that have been suggested in the past.

Many of the appliances now in use either fail to work with a sufficient amount of powder for more than one or two applications, or work fairly well for only a short time. This appliance will be found to work as well with the receptacle full as with a small amount, and when care is taken to keep the powder dry, it is found always ready to deliver either a mere dust or a "snowstorm" of powder, as desired.

It is designed as a single-handed appliance, the handiest form possible. The air-tube that extends into the receptacle is open at its lower end, allowing the tube to be filled with powder to the same level as the powder in the receptacle. The special feature of the insufflator is the lateral perforations permitting the compressed air from the bulb to dust, as it were, the upper surface of the powder and further forces it into the delivery tube without attempting to raise the whole mass of powder, or pack it, as is the usual result with most insufflators now in use. With my apparatus the amount of powder used is easily under control by the pressure given to the air-bulb.

The illustration shows the insufflator with the straight extension tube in place and ready for the

gynecologist. There is also a curved extension tube intended for laryngeal or postnasal work, or for application of powders to the tonsils, as the curved end may be directed up, down, or to the right or left; without these it will be found more convenient for superficial surfaces and ear-work.

It seems to make little or no difference whether it has been carried upside down or not, as it at once responds on pressing the air-bulb.

The insufflator is made by the Pulvola Chemical Company, New York.

## Books Received.

*While the* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

MALADIES DES PAYS CHAUDS. By PATRICK MANSON. 8vo, 776 pages. Illustrated. C. Naud, Paris. Price, Fr. 12.

A TEXTBOOK OF PRACTICAL GYNECOLOGY. By D. TOD GILLIAM, M.D. 8vo, 634 pages. Illustrated. F. A. Davis Company, Philadelphia. Price, cloth, $4.00; half Russia, $5.00 net.

THE TREATMENT OF CERTAIN MALIGNANT GROWTHS BY EXCISION OF THE EXTERNAL CAROTIDS. By ROBERT H. M. DAWBARN, M.D. 8vo, 192 pages. F. A. Davis Co., Philadelphia. Price, cloth, $2.00 net.

THE MEDICAL EPITOME SERIES, ANATOMY. By HENRY E. HALE, M.D. 12mo, 389 pages. Illustrated. Lea Brothers & Co.

A MANUAL OF HYGIENE AND SANITATION. By SENECA EGBERT, M.D. Third edition. 8vo, 473 pages. Illustrated. Lea Brothers & Co.

THE NATURE OF MAN, STUDIES IN OPTIMISTIC PHILOSOPHY. By ELIE METCHNIKOFF. Translated by P. C. MITCHELL, M.A. 8vo, 309 pages. Illustrated. G. P. Putnam Sons, New York. Price, $2.00 net.

PHYSIOLOGISCHE UND KLINISCHE UNTERSUCHUNGEN ÜBER DAS GEHIRN. By DR. EDUARD HITZIG. 8vo, 618 pages. Illustrated. August Hirschwald, Berlin.

### ELECTRICITY IN GENERAL PRACTICE.

BY W. B NEFTEL, M.D.,
NEW YORK.

IT has often been asked if electrical treatment could be employed with advantage by the general practitioner, and of late, with the introduction of various new, complicated and costly apparatus, the question has become more urgent.

In my opinion, based on a long and extensive experience in electrotherapeutics, every educated physician, every general practitioner should resort to electricity in suitable cases. In the first place, because some grave affections of the nervous and muscular systems, the diagnosis of which is difficult and often impossible, can be easily recognized by electrical exploration and successfully treated by the same means that serve for their diagnosis. Again, because the brain, the spinal cord, the eyes, the nerves, the muscles are electrical organs, and their functions are accompanied by electrical phenomena in accordance with certain well formulated physical laws. *A priori*, therefore, these organs and their functions must necessarily be influenced by electrical treatment—an assumption corroborated by clinical observation. Besides these special organs, the whole body is an electrolyte and as such is subject to the electrolytic and kataphoric action of the current.

Since the experimental researches of Hertz have widened the domain of electricity, having proved that all manifestations of light are electrical phenomena, phototherapy, Roentgen rays, etc., have to be included in electrotherapeutics.

The modern theory of ions, the recent researches on radioactive substances, on Hertzian waves and on the ultimate constitution of matter-electrones, have added so much to our knowledge of electrical energy that the application of electricity to science, art, and the various requirements of common life is constantly increasing. There can be no doubt that electricity is destined to play an important part in the hygiene and the therapeutics of the future.

The history of medical electricity is the history of electricity in general, as every discovery in this science was immediately applied to physiology, medicine and surgery, and some of the greatest discoveries in electricity were made by physicians (Galvani, Helmholtz, Dubois Raymond, and others) and by many physicists and chemists who were originally medical men. In fact, until the middle of the nineteenth century electricity found its application almost exclusively in medicine.

The objection that complicated costly apparatus are a drawback to the employment of electricity by the general practitioner, is more imaginary than real. These apparatus and some modern innovations in electrotherapy are necessary only to the specialist for further researches, etc.* For the general practitioner a good portable apparatus for the galvanic and faradic currents is sufficient. It must contain a galvanometer, a rheostat, a commutator; electrodes of different sizes, some of solid metal and some pliable, and special electrodes for the eyes, ears, larynx, uterus, rectum, etc., an interrupter and a faradic brush. This is sufficient for electric exploration and treatment.

With these simple apparatus the laws of electrophysiology were discovered and the most important researches and studies accomplished in electric diagnostics and electrotherapeutics (classical electrotherapeutics).

In every branch of therapeutics empiricism preceded the scientific knowledge of remedial agents and of their mode of action. Thus, previous to the discovery of iodine and its salts, physicians empirically employed it in the form of a burnt sponge (spongia usta) in the treatment of goitre and enlarged glands; for centuries iron was administered in anæmic and chlorotic conditions without any knowledge of hæmoglobin and its functions; cinchona bark was used in intermittent fevers, before the action of quinine on plasmodium malariæ had been discovered. Electrotherapeutics makes no exception to this rule, and electricity, too, was used empirically in the remotest antiquity in the treatment of different chronic diseases of the nervous system. Hippocrates, Galen, Plinius describe a method of treating rheumatism, gout, headache, neuralgias, anæsthesia, paralysis, etc., by placing in the baths of the patients electric fishes whose shocks produced a beneficial effect.

But electrotherapeutics really begins with the invention of the electric machine and the Leyden jar. Much was then written on static electricity, on its action upon the human system in health and disease, with many remarkable observations and reports of wonderful cures. The treatment with static electricity became very popular, but was soon taken up by laymen and charlatans and applied to every kind of disease. A more critical examination of the merits of such electrical treatment disappointed the profession and the method fell into discredit and gradually into complete disuse. It so remained for nearly a century, until about 1880 Charcot reintroduced the treatment with static electricity in hysterical affections.

In reading the publications of the early period of static electricity, one is struck at the wonderful cures reported by men of science and conscientious, honorable physicians.† However, at present we are able to explain these results by assuming that some of these cures were obtained by psychical impression —suggestion in hysterical cases. Similar results are of daily occurrence in the practice of every physician, but they are not published under false pretenses.

Suggestion has been the subject of much discussion, but there still remains a great deal to be said for and against it. In fact, every kind of treatment, almost every action of the intelligent human being, is more or less prompted by suggestion or auto-

*Details of these will be given in a separate article

†Kratzenstein: "Abhandlung von dem Nutzen der Electricität in der Arzneiwissenschaft." Halle, 1743.
Jallobert: "Experiences sur l'électricité." Paris, 1748.
Cavallo: "Essay on the Theory and Practice of Medical Electricity." London, 1780.

suggestion. Some systems of treatment are to a certain extent based on suggestion and even surgical treatment is not entirely exempt from it. Thus the removal of the uvula in hysterical cough, or the more serious operation of oophorectomy in affections of an hysterical nature, act mostly by suggestion and could be replaced by much milder methods. The same can be said of numerous tenotomies of the eye muscles, the bloody dilatation of the urethral orifice, etc. In electrotherapeutics, too, suggestion cannot be excluded, but it does not prevent the current from exercising its physical and physiological effect on the nerve centers and on the whole body in the healthy and morbid conditions. On the whole, however, suggestion sometimes does as much harm as good. Thus, the accumulation in a patient's mind of wrong and unhealthy suggestions which resist every rational treatment often retards the restoration to health. Such patients say: "I have already tried this unsuccessfully," or "It has done me harm." They object to acids, alkalies, iron, quinine, etc., to exercise, rest, and, in fact, to everything indicated in their case.

Miss C., aet. thirty-five, was treated for years by eminent physicians and gynecologists. Her condition became precarious and alarming and Dr. J. Marion Sims referred her to me in 1868. I found the heart weak, a bad circulation and general malnutrition. She was anæmic, emaciated, and suffering from dyspepsia, amenorrhœa, insomnia, and malaria. She said she could not take milk, "as it always gave indigestion," nor could she taste eggs in any shape, "they made her bilious"; fish invariably acted as a poison, so did some kinds of meat; sugar or sweets gave her the gout; tea and coffee increased the insomnia; one-tenth of a grain of quinine would drive her crazy. It took a long time to rid her of these morbid suggestions. She ultimately recovered under the galvanic treatment, and is now a healthy old lady, enjoying all the nourishing articles of food which she formerly disliked. One of her favorite remedies at present is quinine, which she takes whenever necessary in pretty large doses.

Mr. ——, an eminent jurist, with an inherited neuropathic constitution and for years a sufferer from an aggravated form of neurasthenia which resisted every treatment here and abroad. When he consulted me I decided to observe the patient for a while before selecting a method of treatment. Very soon, however, he unexpectedly came to my office in great distress with a severe headache, gastralgia, pains in the extremities and general prostration. He had not slept for forty-eight hours, and had scarcely taken any food. His family physician had to administer morphine hypodermically, which alleviated somewhat the suffering, but the headache, præcordial distress, various hyperæsthesias and prostration continued. I employed galvanization of the brain, under which the morbid symptoms immediately subsided. The patient then told me whenever the barometer was high and the atmosphere clear and bracing he would invariably have such attacks of distress and nervous prostration; that years ago a distinguished neurologist explained to him this peculiarity of his disease, and in his own experience he had found it correct. It is obvious that suggestion had something to do with the severity of the attacks; but it does not follow that the success of the electric treatment was equally due to suggestion, because the action of electricity in the living body, like in any other electrolyte, is objective and positive, and is as certain as the production by electricity of heat, light, motion, etc., in inanimate bodies. In electrotherapeutics, therefore, besides the psychic effect of a possible suggestion, the physical, chemical, and physiological effects of electricity are always present and known to every one who experimentally studied electrophysiology.

In referring to the early history of electrotherapeutics I merely wanted to show its true relation to suggestion.

Before speaking of electric treatment, a few illustrations of the diagnostic value of electricity may not be out of place.

Professor M., about sixty years old, a distinguished American surgeon, consulted me in 1870 on account of a left facial paralysis which developed quite rapidly several weeks before he came to me. It was considered of cerebral origin because of the presence of arteriosclerosis, accordingly an unfavorable prognosis was made. The electric examination, however, gave degeneration reaction (of moderate degree) in all the muscles controlled by the affected facial nerve. Such a result does not occur in cerebral hemorrhages (for instance, in the internal capsule). I made the diagnosis of peripheric or rheumatic paralysis (affection of the peripheric-motor neuron), and the favorable result of the electric treatment confirmed the diagnosis.

Miss D., aet. 37, had an attack of fever with severe headache and pains in the left arm. These symptoms disappeared in a few days but were followed by paralysis of the right extremities; the paralyzed upper extremity gradually regained its function, but the lower one remained paralyzed. The case was pronounced hysterical paralysis. She placed herself under my care in 1900, two years after the paralytic attack. Her general health was very bad, her complexion sallow, she was emaciated and suffered from headache, indigestion, insomnia, constipation, and general debility; she used a crutch, walked with great difficulty, and could scarcely go up or down the stairs. The paralyzed lower extremity was cold to the touch and very much atrophied, especially the extensor and abductor muscles. In some of these, the direct and indirect electromuscular contractility, both faradic and galvanic, was abolished, in others it was greatly reduced, while in all other contiguous muscles the electromuscular contractility remained normal. The case was evidently one of poliomyelitis anterior of the adult, in which some of the ganglionic cells of the anterior horns were entirely destroyed, others more or less injured, the rest remaining intact. The attack was probably caused by the invasion of pathogenic bacteria into the spinal cord from the intestinal canal, the predisposing cause being the long-continued constipation. Poliomyelitis anterior of the adult is analogous to the infantile spinal paralysis, but gives better results, the arrest of growth in the infant being against a favorable prognosis. Miss D. was treated daily with galvanization of the spine and with very strong galvanic and faradic currents of the nerve trunks and of all the paralyzed muscles. A long experience has taught me that the stimulation of the muscles and nerves influences them favorably in a direct way, and besides, is propagated through them to the affected motor ganglia of the anterior horns. This stimulus improves their nutrition and functional activity, enhances the circulation and thus leads to the restoration of the injured ganglia. In the present case the gradual improvement was noticeable from the beginning of the electric treatment. After two months the patient could walk, even up and down the stairs, without a crutch, and went home, intending to return to New York in a few months. The improvement continued during her absence. An additional treatment of two weeks produced a still further improvement in the extensor and abductor muscles, the atrophy of the limb dis-

appeared and scarcely anything abnormal could be noticed in her locomotion. Possibly some of the restored motor ganglia and nerves had vicariously taken up the functions of the degenerated ones.

In cases of myasthenia gravis and myotonia an examination with the faradic current alone is sufficient for the correct diagnosis; the characteristic myotonic and myasthenic reactions are pathognomonic of these morbid conditions and render diagnostic errors impossible.

Not only the general practitioner but the oculist and aurist might derive valuable assistance from the electrical explorations and treatment. The classical researches of Brenner* have demonstrated that when the normal auditory apparatus is placed under the influence of the cathode a distinct sound is heard at the closing which is not heard at the opening of the circuit. When, however, the active electrode is the anode. the sound is quite loud at the opening of the current, but no reaction is perceived at the closing. The galvanic reaction of the auditory apparatus is therefore analogous to Pfluger's contraction-law of the motor nerve, *i.e.* the nerve is excited at the beginning of catalectrotonus and at the end of analectrotonus. This normal formula may differ quantitatively and qualitatively in pathological conditions; the acoustic reaction may be excessive—hyperæsthesia of the auditory apparatus, or it may be considerably reduced—torpor; again, it may be abolished—paralysis, or it may be perverted when the reaction takes place at the wrong moments of excitation.

On these abnormal reactions is based the rational galvanic treatment of intractable noises, tinnitus aurium and other morbid conditions.

Equally important is the diagnostic value of the galvanic vertigo. When the normal auditory organ is placed in a certain way, under the influence of the galvanic current, vertigo will take place, with a tendency to fall toward the side of the anode. In cases of one ear being affected the inclination of the head will be on the side of the affected organ, regardless of the electrode (Babinsky's sign). In cases of bilateral lesions of the labyrinth with deafness there will be neither vertigo nor any inclination of the head. In hysterical deafness, on the contrary, the vertigo and inclination toward the anode will persist like in the normal condition.†

The galvanic reaction of the optic apparatus, like that of the acoustic, is of diagnostic and therapeutic value.‡

In the normal condition of the eye, under the influence of the anode a blue disk surrounded by a violet ring is seen, and under the influence of the cathode the disk is of a yellowish green and the ring yellow. In some cases, instead of a round blue and yellowish green, a black and white disk of oval form is seen. At the appearance and disappearance of the disk, a flash of light is perceived. The sudden increase and decrease of the current-intensity acts as the opening or closing of the current.

The galvanic reaction differs in various morbid conditions of the optic apparatus, and the current exerts a beneficial effect, especially on its nervous and muscular structures.

No strict rules can be laid down with regard to the indications for the employment of either the galvanic or faradic current. Sometimes both currents, for different purposes, can be used in the same case. Generally speaking, the galvanic current acts directly upon the brain, the spinal cord, all the nerve-centers and the organs of the higher senses. It produces a modification of the excitability in the nerves—*electrotonus*—and is thus indicated in paralysis and convulsions, in anæsthesias, hyperæsthesias, and neuralgias.

The faradic current is indicated as a local and general stimulant and tonic. It stimulates the motor, sensitive, and vasomotor nerves; it acts by reflex upon the centers of circulation and thus affects the general nutrition. It is also indicated in neuritis.

The galvanic current is mostly indicated in plethoric and the faradic in anæmic persons. This is naturally subject to many exceptions.

In my opinion the contraindications to the use of both galvanic and faradic currents are fevers and acute inflammatory diseases.

**Faradic Current.**—The faradic current is of great value to the general practitioner in a variety of chronic and emergency cases of daily occurrence.

There are different methods of using the current:

1. By applying the active electrode to a motor nerve or muscle and the other at some distance—Duchenne's *electrisation localisée;* by this method he discovered many physiological and neuropathological facts and inaugurated the scientific electrodiagnostics and therapeutics.

2. One electrode is applied to some part of the body while the other is moved over the affected region—labile application.

3. Both electrodes are kept steadily in their places—stabile application, while the current is gradually increased to a maximum and reduced to zero several times—swelling or surging currents.

4. While one electrode is kept steadily in its place the other is alternately applied and removed, the current being at high intensity—tetanizing current. The same result is obtained with a strong current when both electrodes are kept in their places, the active being provided with an interrupter.

5. The indifferent electrode is kept in one place while the active, in the shape of a metallic brush, is moved over the affected part—faradic brush.

Finally, the faradic current may be used simultaneously with the galvanic current—galvanofaradization. This method is more powerful than when the two currents are used separately, because the nerves and muscles are stimulated while in the electrotonic state.

*Faradization of the Phrenic Nerves in Suspended Animation.*—In 1862. when making some experiments on dogs in the physiological laboratory of Prof. George Harley in the University College, in London, chloroform anæsthesia was prolonged until respiration and heart's action ceased and life appeared extinct. Applying one electrode of a strong faradic current to the neck over the phrenic nerve, the other electrode was applied and removed about eighteen times in a minute at the phrenic nerve of the other side; this called forth strong contractions of the diaphragm and other respiratory muscles and restored the animal to life.

Several times in suspended animation, caused by anæsthesia during operations, I was called upon to demonstrate to physicians in New York the efficiency of this method on human beings. The electrodes were applied steadily to both phrenic nerves while the current was alternately increased and diminished until respiration was restored.

This method in a modified, much milder form gives excellent results in a variety of cases of nervous prostration, of collapse, of heart failure. In dyspnœa, too, whether in consequence of pulmonary congestion or œdema of the lungs, etc., it can ad-

‡Neftel: "Galvanotherapeutics," 1871. *Virchow's Archiv*, Bd. 97, 1880.

vantageously replace inhalations of oxygen. The effect of these inhalations is problematic, since the blood or rather the erythrocytes which are the real carriers of oxygen are unable to absorb more than the quantity of oxygen normally diluted in pure air. In all these cases faradization of the vago-sympathicus is often followed by an immediate improvement of the cardiac and respiratory symptoms.

*Treatment of Writers' and Piano Players' Cramp.*—An ascending galvanic current is passed through the nerve trunks of the affected extremity and is followed by tetanizing faradic currents applied to the extensor and flexor muscles. The treatment is repeated daily until recovery.

Miss E., aet. 23, of a good constitution, suffered for two years from players' cramp in consequence of strenuous exercising on the piano. She had to give up playing altogether, as the mere touching of the keys called forth a cramp. I treated her as follows: An ascending galvanic current was sent through the right brachial nerve, the cathode being steadily applied first to the brachial plexus and then to the nape of the neck, the anode to the brachial nerve and its ramifications at the wrist. The current was gradually increased to a considerable intensity during several minutes and diminished. After this faradic swelling and tetanizing currents were applied alternately to the extensor and flexor muscles of the arm, forearm, and hand. The patient felt the arm invigorated from the first treatment, which was daily repeated until the disappearance of the affection. She had no relapse. I treated by the same method with good results writers' cramp, both the spasmodic and the paralytic forms. The rationale of my method consists in reducing the morbidly exaggerated excitability of the motor and sensitive nerves by the galvanic current, while the tetanic contractions, induced by the faradic current, render them less sensitive to the comparatively milder contractions in writing or playing.

*Dilatation of the Stomach and Gastroenteroptosis.*—In 1876 I described* the following method of treating chronic gastric catarrh with dilatation and lowering of the stomach: Two flat electrodes are applied to distant parts of the stomach, increasing to a maximum the current intensity and diminishing it to zero. Having repeated this several times, the electrodes are placed opposite each other in other directions and the current-intensity again repeatedly increased and diminished. These applications are made daily and supplemented with rational dietetic régime and medicinal treatment. Later, after Glenard's publications on enteroptosis, I continued to employ the above described method, adding faradization of the bowels and other abdominal viscera, since dilatation of the stomach is always accompanied more or less by enteroptosis.

Mr. F., aet. 50, suffered from an aggravated form of dyspepsia, contracted in the mining districts of the West, where he could not be regular in his diet or mode of living. The most unpleasant symptom was an accumulation of gas in the stomach and bowels, with frequent loud eructations, which excluded him from society. He was anæmic, emaciated, the bowels costive, alternating with diarrhœa and other symptoms of chronic gastrointestinal catarrh and gastroenteroptosis in a marked degree. I treated, with swelling faradic currents, the stomach, colon and other intestines, at first daily and later three times a week or occasionally, combining the faradic treatment of the abdominal organs with galvanization of the brain. During a prolonged treatment all morbid symptoms disappeared by degrees.

That the faradic current reaches the stomach and bowels is plainly visible and palpable, especially in emaciated persons. Besides this direct influence, produced by the strong currents, there is a correlation, by reflex action, between the stimulated external regions and the subjacent organs, in consequence of which their circulation and nutrition are favorably modified.

*Movable Kidney.*—The movable kidney being a visceral ptosis, I treat it with faradic currents in a similar way to other forms of enteroptosis. It is of frequent occurrence in women, especially on the right side, owing to an anatomical predisposition, and is mostly caused by tight lacing.

Mrs. G., mother of two children (1896), suffered from dyspepsia, costiveness, and pain in the right lumbar region, which at times compelled her to keep the bed. She was very anæmic, emaciated, with a dilated stomach and gastroenteroptosis. The lowered right kidney could be palpated through the thin abdominal walls. The treatment was as follows: Two good-sized electrodes were firmly applied to the hypochondriac regions and the current-intensity considerably increased and diminished several times during half a minute; the electrodes were then placed somewhat lower—on the line of the umbilicus; then on both inguinal regions and the current repeatedly increased and diminished at each place; one electrode was then applied to the epigastrium and the other to the hypogastrium, again increasing and decreasing the current as before; now leaving one electrode at the epigastrium, the other was removed to the left hypochondrium and then changed to the right, every time using the current in the same way. One electrode was then placed upon the right lumbar region, the other upon the right hypochondrium, and finally both electrodes were applied to either side of the lumbar region. At every place of application the swelling faradic currents were allowed to flow for half a minute, producing strong muscular contractions. The treatment was continued daily for a month and occasionally repeated later. It gradually removed the dyspeptic symptoms, the costiveness, the gastroenteroptosis and kidney trouble, and restored the patient's health.

*Hernia.*—Many years ago, in treating gastroenteroptosis with the swelling faradic currents, I observed the beneficial influence they exerted upon inguinal and femoral hernia whenever it complicated enteroptosis.

Mr. K. (1874) complained of dyspepsia, gastralgic pains, frequent eructations, insomnia, costiveness; he was irritable, with symptoms of gastric catarrh and considerable ptosis of the stomach and colon. He wore a truss, for two years, on account of a right inguinal hernia (the size of a small fist when protruding). I treated him by the method above described, the morbid symptoms gradually disappeared and his general health steadily improved under this treatment. He told me that some time ago, during the treatment, he had laid aside the truss, the hernia showing no tendency to protrude, even under forced coughing. Encouraged by this unexpected result, I intensified the faradization of the abdominal muscles, especially at the hypogastric and inguinal regions, thus producing strong tetanic contractions of the abdominal and partially of the crural muscles. From that time the patient has not had a trace of hernia and consequently never again needed a truss.

Since this experience I treated successfully by this method a number of cases of hernia in every

*"Die Behandlung der Magenectasien," *Centralblatt für die medicinische Wissenschaft*, 1876.

one of which I found an undeveloped condition of the abdominal muscles, either congenital or acquired. Under the tetanizing faradic currents the muscles increased in size, became strong and prevented the protrusion of the hernia. I begin the treatment by applying to the inguinal regions large electrodes of a strong galvanic current with frequent voltaic alternations; this is followed by swelling faradic currents, the electrodes remaining in the same place; now one of the electrodes remains on the inguinal region while the other is applied separately to each abdominal muscle with swelling faradic currents; the same is repeated on the other side; then, one of the electrodes is carried to the lumbar region while the other is applied alternately to either inguinal region with swelling faradic currents producing strong contractions of the abdominal and femoral muscles. Sometimes I use galvanofaradization.

*General Anæmia.*—The faradic current, indicated in cases of general anæmia and malnutrition, especially when complicated with hysteria and neurasthenia, is used by me in the following way: One good-sized electrode is applied to the nape of the neck, the other is held firmly by the patient, first in one, then in the other, hand while a mild current is gently increased and decreased. One of the electrodes is then placed upon the hypogastrium, the other slowly moved up and down the vertebral column, the current being of considerable strength; both electrodes are now placed to the upper crural regions, under Poupart's ligaments, with swelling faradic currents, producing strong muscular contractions, and lastly both electrodes are applied to the popliteal fossæ. In each application the polarity of the current is repeatedly changed.

In cases of anæsthesia and in neuritis the faradic brush is used.

*Galvanofaradization in Atrophic Conditions.*—In cases of paralysis with atrophy both the galvanic and faradic currents often have to be used simultaneously, as the paralyzed and atrophied muscles and nerves yield more readily to their combined action.

Mr. S., lawyer, of this city, aet. 26, while a student in Harvard injured the left knee in athletic games. The sudden pain was intense and became continuous, and notwithstanding a prolonged rational treatment he could not walk without crutches. In February, 1898, two years after the accident, I found on examination a tall, well-built, muscular, and very strong young man, although somewhat anæmic owing to suffering and want of exercise. All his organs and functions were perfectly normal except the left lower extremity, which was very much atrophied, cooler to the touch and more anæmic than the right extremity, the muscles of which were highly developed (hypertrophied) and made the contrast more apparent; the two limbs looked as if belonging to different individuals. The electromuscular contractility, both galvanic and faradic, of the left leg showed degeneration, reaction in various stages, caused by traumatic neuritis. The right leg responded to the currents normally, although in a somewhat exaggerated manner. The treatment consisted in daily galvanofaradization of all the nerve trunks and muscles of the affected extremity with very strong galvanic currents, voltaic alternations and swelling faradic currents with frequent reversions of polarity. The contractions thus called forth were at first very feeble, but after repeated treatments gained in strength. The patient every day felt more life in the left limb, which to the touch appeared warmer, and the muscles gradually increased in volume, their reaction becoming more vigorous and normal. At the end of a month he could walk naturally and without crutches; the treatment being continued, with interruptions, a couple of months longer. I saw the patient a year later, when no difference could be detected in the appearance and functions of the lower extremities.

Mr. W., a prominent business man of this city, in crossing the Atlantic was thrown off his feet during a severe storm and fractured both bones of the right forearm. He was attended in London by one of the leading surgeons and remained under his care until the end of the treatment. Notwithstanding a perfect consolidation of the fracture, a severe pain in the arm and hand remained, and was complicated with a development of atrophy and paralysis of the extremity, especially of the fingers. By the advice of his attending surgeon and consulting physicians he took the baths and electrical treatment at Aix les Bains; the atrophy kept increasing, however, and the pain, still acute, prevented sleep and influenced the health.

Several months later I saw the patient in New York. The muscles of the right arm and hand were very much atrophied, especially those of the thenar, the hypothenar and the interossei; electrical examination with both currents showed a high degree of degeneration-reaction; not the slightest movement could be made by the fingers or wrist, nor could the arm be lifted or bent at the elbow. The pain was intense and continuous. It was evident that at the time of the accident some motor and sensitive nerves were injured—lacerated by the sharp ends of the fractured bones, and produced the severe neuritis with its sequelæ—atrophy and paralysis. The treatment consisted of galvanofaradization of the brachial plexus, brachial nerve and its ramifications, and of all the muscles of the arm and hand. The first treatment gave relief and a night's rest, having subdued the pain. Under daily treatment a very slight mobility became gradually noticeable, which after a while increased more rapidly until the functions of the nerves and muscles were nearly restored; at the end of three months the arm and hand could be used almost normally; the pain left him soon after the beginning of the treatment. Circumstances prevented the patient from completing the treatment.

In these two instances the galvanofaradization was the only means to save the extremity from complete atrophic paralysis, especially in the case of the right arm, the loss of which is always more keenly felt.

In the following case not only the limbs, but the life of the patient was saved by this method. Mr. R., over seventy years old, contracted a cold in March, 1887, which laid him up with high fever pains all over the body, great weakness and impossibility to move either upper or lower extremities; the disease was obviously of an infectious nature. The fever gradually subsided, leaving pain and great weakness in the lower extremities; in the upper extremities besides the pain atrophic paralysis developed. I examined the patient in October of the same year. I found him of a delicate constitution, emaciated, very feeble, the pain preventing sleep; he could not himself change his position in bed, and had to be helped even with the food, of which he could partake but very little. I made the diagnosis of polyneuritis of the motor and sensitive nerves. The prognosis in such cases—at an advanced age in decrepit persons—is generally fatal. I used galvanofaradization of the affected nerves and muscles with strong currents, voltaic alternations and faradic swelling currents with

frequent reversions of polarity. The pain yielded very soon, while the mobility improved slowly and gradually. At the end of several months he could walk and use the arms and hands naturally; the general health was restored; the treatment, however, was continued occasionally for some time until complete recovery.

*Faradic Current in Heart Diseases.*—I found the faradic current of great value not only in functional but in organic diseases of the heart. Chronic myocarditis and the degeneration of the myocardium constitute the principal danger in organic cardiac affections, the treatment is therefore directed toward restoring the nutrition of the heart. I employ the following method: A large negative electrode is applied (stabile) to the nape of the neck, a smaller positive electrode to the jugulum sterni and the current gradually increased and diminished several times; then the small electrode is placed over the vagus and sympathicus and the current again increased and decreased several times, the same being repeated on the other side; finally, the positive electrode of a moderate current is moved along the lateral and anterior surface of the neck, the negative electrode remaining steadily in the same place. This treatment is continued daily for a considerable time. It affects in a direct manner and by reflex the vagus and the sympathetic, strengthens the heart's action, the circulation and nutrition, prevents heart failure and renders the valvular diseases almost harmless by producing hypertrophy of the cardiac muscle.

The secondary effects of organic cardiac diseases, hydropic effusions, engorgements of the viscera and cyanosis, gradually disappear under this treatment.

Mrs. M. of Albany, N. Y., about thirty-six years old and mother of several healthy children, came under my care in 1885 with a diagnosis made by eminent physicians in Albany and New York of an organic heart disease of long standing, aortic stenosis and dilatation of the left ventricle. The patient comes from a healthy family, her father was a well preserved octogenarian and her brothers and sisters were all healthy married people. Although well built she was always the weakest of the family and anæmic since an attack of rheumatism. During a year or more she became subject to fainting, and would suddenly fall even in the street and remain unconscious for some time. All exercise was then forbidden and she was not allowed to walk up the stairs. Her pulse was very weak and easily compressible and the heart's action feeble; she suffered besides from a severe trigeminus neuralgia. I regulated her functions, ordered a methodically increased daily outdoor exercise and began at once the faradization of the neck by the above described method. Besides this, I occasionally used galvanization of the brain with mild currents. The patient's health improved steadily under a continuous treatment of several months, which was repeated at intervals until the disappearance of all morbid symptoms. The patient, after the lapse of so many years, appears in perfect health, the heart's action is regular and strong, the pulse normal, she can walk long distances, climb mountains, play golf—in fact, she has become the strongest of the family. Complete compensation of the valvular affection must have taken place under the combined action of electrical stimulation of the cardiac muscle, exercise and the removing of obstacles to the free circulation of the blood.

In treating organic heart disease special attention must be given to digestion. I observed that the overfilling of the stomach with indigestible food produces irritation of the cardiac vagus by reflex from the gastric branch of the pneumogastric; this arrests the heart's action and is followed by fainting and heart failure. Mild aperient mineral waters remove the obstacles to free circulation. In chronic cardiac diseases, judicious and methodically increased muscular exercise in the open air is of utmost importance.

**The Galvanic Current.**—Rational electrotherapeutics bears the same relation to electrophysiology as rational medicine bears to physiology. Indeed, the whole doctrine of electrodiagnostics and electrotherapeutics becomes intelligible and clear only in the light of experimental electrophysiology. It teaches, for instance, that the brain, the spinal cord, the organs of higher senses possess inherent electrical currents which obey certain laws and undergo changes during their functional activity (negative variation, etc.). Thus, when a galvanic current passes through a motor nerve, this latter responds with a certain visible reaction—a contraction of the corresponding muscles—and at the same time undergoes a certain modification of its excitability. in the sphere of the cathode the excitability may be increased to such an extent that the slightest excitation, mechanical, chemical, or faradic, which would scarcely produce any contraction before the passage of the current, will now call forth strong tetanic contractions. In the sphere of the anode a lowered excitability obtains, and even strong faradic stimulation will produce but a slight contraction or none at all, whereas before the anelectrotonic condition it would have called forth tetanus. The galvanic current acts in the same way upon the sensitive, vasomotor and other nerves and the nerve-centers, producing analogous modification of their excitability; for instance, in the sensitive nerves—hyperæsthesia, anæsthesia, analgesia, etc.

Theoretically it would seem easy to construe electrotherapeutics on the basis of electrophysiological principles, but it is not so in practice. We cannot always determine in the living body the direction in which the current flows, because of the multiplicity of heterogeneous tissues and their different conductibility. Brenner therefore introduced the polar method, where the anode practically represents the ascending current and the cathode corresponds to the descending current. Since the physiological and therapeutic effect of the anode and cathode differ as widely as their electrolytic, chemical effect, the active electrode alone is applied to the affected part while the other, the indifferent electrode, is placed at a considerable distance, in order not to interfere with the action of the former. In morbid conditions the altered structures react differently from the normal, and in the motor nerve, for instance, the anodic reaction often prevails over the cathodic. According to electrophysiologic law, the increased sensitiveness in neuralgia should be subdued by the anode, but sometimes it will on the contrary increase the pain, which, however, will yield to the cathode; in some cases, as in neuritis, only a strong irritation with the faradic brush will bring relief. Again, where the anode subdues the pain, it will sometimes carry it to the corresponding nerve of the opposite side; in such cases, in order to prevent this complication I apply to the symmetrical nerves a bifurcated anode (my polar symmetrical method).

In the normal auditory apparatus the cathode produces a distinct sound, like the ringing of a bell, which instantly ceases under the influence of the anode. Thus the latter can be used to abolish tinnitus aurium. But in pathological conditions

the reaction of the auditory apparatus is often perverted, and the noises can be stopped only by the cathode. When the reaction is paradoxical, *i.e.* when the noises cease in one ear to appear in the other, a bifurcated electrode applied to each ear brings both under the influence of the same active electrode and abolishes the noises.

These examples show that electrophysiology has to guide electrotherapeutics, but the physician must find his own methods based on clinical observation.

The limited space of this article allows to describe but a few electrotherapeutic methods and to briefly allude to the principles on which they are based.

*Galvanisation of the Brain.*—A mild galvanic current applied to the head may call forth cerebral symptoms—flash of light, taste, sound, vertigo, etc., which prove that the current, percutaneously applied, affects the brain directly, and not by reflex, and acts upon the vasomotor nerves and the circulation. The galvanic current, being the normal stimulus for the brain, is indicated in all functional and some organic cerebral affections; in neurasthenia, hysteria, hypochondria, in mental diseases, insomnia, etc. Even organic diseases of the brain, which are generally preceded and accompanied by cerebral congestion, anæmia, and other vasomotor disturbances, are favorably influenced in the first stage. As galvanization of the brain improves the circulation and nutrition of the nerve centers and these latter control all the functions of the body, it is obvious that their improvement affects the whole system. My method is described in the *Archiv für Psychiatrie und Nervenkrankheiten*.

Mrs. L., about forty years old, suffered from deep melancholia without delusions since her husband deserted her six years before. She was very anæmic and emaciated, pulse slow and easily compressible, all the functions retarded. She constantly remained quiet, exceedingly depressed, scarcely uttered a word, ate very little and had only a broken sleep. A friend accompanied her to my office and gave the anamnestic data while the patient sat silent, motionless, even the facial muscles remaining immovable and presenting a masklike appearance. The eyes alone expressed intelligence and showed that she was aware of her surroundings. Soon after I began the galvanization of the brain the face gradually assumed a more natural appearance, she smiled and said she felt better, and at the end of the application she looked differently, gave me some details of her condition and walked cheerfully away. Under the continued treatment she recovered and resumed her former occupation.

Mr. E., about forty-three years old, formerly healthy, very active and one of the best students at college, where his professors and colleagues predicted for him a brilliant literary career. After the death of his young wife, several years ago, he lost his former ambition and energy, became inactive, irritable and capricious, quite in contrast to his former good-natured and amiable disposition. He complained at first of a dull headache, various paræsthesias and other neurasthenic symptoms. Later he suffered from præcordial distress, congestions to the head and different vasomotor disturbances. These latter symptoms would assume at times an acute exacerbation in the form of attacks of insomnia, intense psychical depression, accompanied with dyspnœa, præcordial distress and suicidal tendency which would last for weeks without yielding to any treatment, and would only gradually subside, leaving the patient weak and depressed for many months and sometimes until the appearance of a new attack. The morbid condition presented a strange combination of neurasthenia, hysteria and recurrent melancholia (described by me in the MEDICAL RECORD, 1898, June 11. He had been treated with but little success by a variety of methods; during the acute attack no remedy would alleviate the suffering; no hypnotic would produce sleep if administered in the ordinary doses, and the patient seriously contemplated suicide. Galvanization of the brain, however, gave immediate relief and removed the præcordial distress, the dyspnœa and insomnia. By continuing the treatment for some time supplemented by galvanization of the cervical sympathetic the patient would rapidly recover and would remain comparatively well until, under the influence of some depressing emotion, a new attack would be called forth and would again yield to galvanization of the brain.

Miss G. of this city, aet. twenty-eight, came came under my care twenty years ago, suffering since her fifteenth year from intense headaches, which would not yield, even temporarily, to anything but a complete anæsthesia by ether, which had to be kept up, with interruptions, for twenty-four hours or more, once a week and sometimes oftener. She was otherwise of a good constitution, but with a tendency to congestions to the head. The galvanization of the brain brought a speedy relief, the headaches became milder after each application, less frequent, and could be borne without ether. After a while the headaches left her entirely and have never returned. She still continues in perfect health.

Rev. Mr. A., aged fifty-five years, an eloquent preacher and scholar, of a very nervous temperament, suffered for many years from insomnia, and complained of different neurasthenic symptoms and was very much run down. He went to Europe in search of health, but on reaching Paris began to hallucinate with a complete confusion of ideas. It became necessary to place him in an asylum and Dr. Brown-Sequard telegraphed his family in Boston that he was probably hopelessly insane. When his condition improved somewhat he was brought back to New York and placed under my care in 1877. I found him weak, anæmic, emaciated, suffering from insufficient sleep (for about two to three hours). I treated him daily with galvanization of the brain, which soon brought nights' rest and after a while he could sleep for seven or eight consecutive hours. His general health improved with the regained sleep, and allowed him to resume, with renewed energy, his former work. He published later a new volume and has since continued to be in good health.

Miss I., school teacher in Washington, D. C., referred to me in 1871 by her uncle, an eminent physician. She suffered for years of otorrhœa, noises in the ears and head, with severe headaches and insomnia. She was anæmic, emaciated, of a sallow complexion, and the countenance expressing intense suffering. I commenced the treatment of tinnitus aurium, at the same time using the galvanization of the brain. After the first treatment she slept almost twenty-four hours, awakening only for her meals, and slept well every following night. She left for Washington in a very satisfactory condition and resumed her usual occupation.

Mr. H., lawyer (1887), aet. forty-one, married, suffered for many years from severe nervous dyspepsia, and gastralgia with occasional vomiting and insomnia. He could not take sufficient food, as many nutritious articles invariably produced indigestion. He complained of general

debility, was anæmic, thin, weak, unable to have any outdoor exercise and often had boils and furuncles. A life insurance company had refused to accept him after examination of the urine, which contained a considerable amount of sugar. I found the patient's heart weak, the pulse small and the muscular system undeveloped; the urine contained more than 2 per cent. sugar. Under the galvanization of the brain and general faradization the glycosuria disappeared and his health steadily improved in every respect. He gained flesh and strength, sleeps well and can now take outdoor exercise; his appetite and digestion are good and all other functions normal.

The incurable progressive paralysis of the insane s preceded by cerebral vasomotor disturbances long before the degeneration and destruction of the nervous elements set in. In the first vasomotor stage I consider the disease curable.

Mr. J., a wealthy bachelor over fifty years old, placed himself under my care in 1881. He was a high liver, and had syphilis, from which he was entirely cured many years ago. His friends and relatives had noticed for some time a gradual change in his temper and general appearance; from a quick, rather aggressive man, exceedingly active, and fond of society and of all sorts of pleasures, he became quiet, passive, even submissive, taciturn, and complained of neuralgias and insomnia. The examination showed that he was of a good constitution and the thoracic and abdominal viscera normal. His speech was slow, hesitating, the pupils somewhat unequal. and reacting sluggishly, fibrillary contractions of the tongue and occasional twitchings of the facial muscles. The knee-jerk was diminished, he walked slowly and complained of sciatic pains, sometimes in the right or left limb and sometimes in both. I pronounced the case progressive paralysis of the insane, with an absolutely unfavorable prognosis. However, the galvanization of the brain and of the cervical sympathetic gave beneficial results, and his general health improved progressively and so remained during twelve years. Together with the galvanic treatment I enjoined a healthy mode of living, forbidding all excesses and alcoholic drinks, and advised being under a constant medical observation. His relatives, who lived with him, thought he was entirely restored to health and concluded to spend a couple of years in Europe. Meanwhile he took up his residence in one of the fashionable clubs and resumed the gay life and excesses, of his youth. I did not see him for eighteen months, when he suddenly came to my office, after an apoplectiform attack, in a hopeless condition. His relatives returned and took him to Europe, where the disease progressed to a fatal termination. I believe the patient might have been saved had he remained under medical observation and led a quiet life, as in the following case.

Mr. R., a bachelor, thirty years old, a successful dentist, with a large and lucrative practice came under my care in 1887. He worked hard, but could not take sufficient sleep; he spent the evenings in society, or places of amusement, indulged in all sorts of excesses, and once acquired syphilis, from which, however, he had been cured. He presented premonitory symptoms of general paresis —great excitability, inequality of pupils, congestion to the head and headache, loss of memory, fibrillary contractions of the tongue and of the facial muscles, insomnia, frightful dreams, diminished knee-jerk. I treated him with galvanization of the brain and cervical sympathetic, and in explaining to him his condition, advised a quiet, healthy, regular mode of living, if possible in the country. The patient followed my advice and has entirely recovered.

The effects of galvanization of the brain are soothing and invigorating; any unpleasant or painful sensation diminishes or disappears, impeded movements become easier, choreatic twitchings cease and patients enjoy refreshing sleep.

Miss S., fifteen years old, only child of wealthy parents, was affected with a severe form of chorea, which resisted every treatment, including arsenic and iron, etc. I saw the patient in 1873. She was thin, very pale, chloro-anæmic, and continuously agitated by more or less violent clonic movements of the head and extremities which seriously interfered with every voluntary movement and were often the cause of alarming accidents. Thus, the day before she came to me the end of a parasol she held in the hand was violently thrust into the nostril and caused a profuse hemorrhage, which was arrested with great difficulty. I treated her for a couple of months with daily galvanization of the brain, under the influence of which she gradually recovered, had no relapse and still remains a healthy lady.

Mrs. L., about sixty-five years old, thin and decrepit, of a sallow complexion, with senile tremor of head and hands, resembling the initial stage of paralysis agitans, complained of dyspepsia, insomnia, backache, and general debility. I treated her with galvanization of the brain until the disappearance of all the morbid symptoms, including the tremor She is still in good health, although now an octogenarian; goes out even in winter, and comes occasionally to be treated with galvanization of the brain.

Mr. B., a cultivated gentleman of this city, controlling large business interests and generally respected for his benevolence and philanthropy. When a young married man he used to have hemorrhages from the lungs and other symptoms of pulmonary phthisis, which, however, gradually subsided, although he always remained in delicate health and very thin. Later he became subject to dyspepsia and diarrhœa with occasional attacks of gastralgia. In 1869 I was called to treat him during the most severe attack of gastralgia and vomiting, which, lasting nearly two weeks, deprived him of night's rest and prevented the taking of nourishment. After he had recovered from this protracted illness he came to my office asking advice in order to prevent similar attacks. I employed galvanization of the brain for several months, with occasional interruptions, until the patient's improvement in every respect became steady. He said that his general health had become better than ever before, and, he continued, for about twenty-five years, to come now and then for a short course of treatment, being always active and cheerful, and retaining all his mental powers at his great age. In consequence of exposure he died of pneumonia in his ninety-seventh year.

In elderly persons a methodical galvanization of the brain is marked by a change in their general appearance. It acts as a natural stimulant and tonic, abolishes tremor, and prevents senile decrepitude; it actually prolongs life and preserves the normal functions and the mental faculties.

*The Sympathetic Nervous System.*—The galvanization of the sympathetic is important because of the large number of its vasomotor secretory, accelerating and inhibitory nerves and ganglia, influencing the circulation and nutrition of the viscera and controlling their involuntary and peristaltic movements.

The galvanization of the cervical sympathetic is indicated in different vasomotor neuroses—Basedow's

disease, migraine, epilepsy, etc., and in the incipient stages of some organic cerebral affections (general paresis).

The cervical sympathetic may be galvanized either by applying one electrode to the superior and the other to the inferior cervical ganglion, or by the polar method, when the active button-shaped electrode is applied to the superior cervical ganglion and the indifferent, a large flat electrode, to the nape of the neck with a very mild current of not more than half a minute's duration, avoiding sudden fluctuations in order to prevent cerebral symptoms. This generally accepted rule is often useful, although sometimes its effect is insignificant or fails altogether. In these cases I use the following method, especially in anæmic or decrepit persons; I rapidly increase the current to a considerable strength with sudden fluctuations and occasional voltaic alternations, decrease it in the same way to zero, cautiously watching the effect.

Rev. Mr. C., aet. fifty-eight, emaciated and anæmic, with symptoms of severe neurasthenia, suffered for years from general debility, insomnia, nervous dyspepsia, gastralgia, dull headache, backache, vertigo, and exhaustion after the slightest mental effort. He was constantly under medical treatment. I, too, treated him at different times with various methods, including galvanization of the cervical sympathetic according to the usual method with mild currents, but with little general improvement, except the backache that yielded to strong faradization of the spine. I then concluded to modify the galvanization of the sympathetic and asked the patient to inform me at once of every sensation he experienced during the application of the current. A flat anode was applied to the nape of the neck and a button-shaped cathode to the superior cervical ganglion; the current was rapidly increased, in a few seconds reversed and decreased with considerable fluctuations to zero. The same procedure repeated on the other side. During the application the patient felt flashes of light, taste, sound, disturbed equilibrium with inclination toward the anode, etc. Immediately after the application he felt general relief, and reported the next day that he had slept soundly all night, had no headache or any other morbid symptom, felt entirely well and was free from gastralgia, although he had imprudently eaten with great appetite. I continued for a fortnight the same treatment.

This method from the first application often changes the entire character and course of a chronic disease and makes it more manageable and yielding to a proper treatment.

I galvanize the thoracic and abdominal sympathetic, including the spinal cord, by the polar method—applying the active large electrode to the dorsal and lumbar vertebræ and the indifferent large electrode to the hypogastric region, beginning with a moderate current and increasing it so far as the patient can comfortably bear. Both electrodes are first kept steadily, then the active electrode is moved slowly without breaking the current, along the vertebral column and its sides, while the indifferent electrode is kept at the hypogastrium; from time to time voltaic alternations are made, while both electrodes remain stable.

The principal vasomotor nerves are the splanchnic nerves; their vascular territory could contain almost the whole blood of the body. As they control the circulation, nutrition and other functions of the abdominal and pelvic viscera, I galvanize the splanchnic nerves in all chronic affections of these organs.

Here I will speak only of a special class of very painful and otherwise intractable affections within the sphere of the abdominal sympathetic, which readily yield to my method.*

Under certain morbid conditions of a neurotic character (general or local) the surface of the excretory canals is in a state of hyperæsthesia, and the mere passage of the normal contents, menstrual flow, urine, fæces, produces spasmodic contractions and intense pain in the terminal part of the excretory canals.

Mrs. H. of Richmond, Va., twenty-five years old, suffered from intense dysmenorrhœa with headache, backache, etc., notwithstanding various treatments and two operations performed by Dr. J. Marion Sims, who asked me to try electricity to alleviate the pain. I commenced the treatment immediately after the period, by my method of galvanization of the splanchnic nerves, and continued it daily until the next period, which was painless, as were all the following. Her general health still remains excellent.

Dr. M., a physician of this city, suffered, for many years, from painful defecation, which prostrated him every morning and disabled him for the day. He could not attend to his practice and was obliged to postpone the movement of the bowels until bedtime. All the usual medicinal and surgical methods, severe stretching of the anus under an anæsthetic, etc., failed, but repeated galvanization of the splanchnic nerves brought relief.

Cases of painful micturition in male patients which had not been relieved by incision of the orifice yielded to the same method of galvanization.

*Galvanization of the Pneumogastric Nerves.*—Asthmatic attacks caused by a spasm of the bronchial tubes (reflex neurosis) are relieved by galvanization of the pneumogastric nerve.

W., twelve years old, whose father, a clergyman, died of asthma, suffered from the same disease and was brought to me by his mother in 1882. The first attacks were each caused by a cold in his ninth year and became gradually more frequent and severe; later they followed indigestion, overexertion or a cold, and soon began to appear without any apparent cause and last many days, a new attack coming on before he could recuperate from the preceding one. He was pale and emaciated and weakened by the suffering and sleepless nights, insufficient nourishment, lack of outdoor exercise. Having regulated his diet, corrected the digestion and the action of the bowels, I commenced the galvanization of the vagus. A rod-like anode about two inches long was applied along the nerve on one side of the neck, a large flat cathode to the nape of the neck, both electrodes were kept in their places while the current was gradually increased to a moderate intensity and slowly decreased. The same was repeated at the vagus of the other side. I treated the patient daily for more than a month. Several times an abortive attack or rather a premonition of an attack would appear but would quickly yield to the current. His general health visibly improved, the pallid cyanotic complexion gave way to a natural color, sleep and all other functions became normal, and he returned to Cambridge, resuming the treatment twice annually the following three years with the most satisfactory results. The attacks never returned. He pursued his studies, graduated from college and now occupies a responsible position as engineer. He is exceedingly active and enjoys excellent health.

In treating the pneumogastric nerve a bifurcated

*Neftel: "Beiträge zur Kenntniss und Behandlung der Visceralen Neuralgien," *Archiv für Psychiatrie und Nervenkrankheiten*, Bd. X, Heft 3.

anode can be used on both sides, with the cathode at the nape of the neck. Care must be taken with regard to the intensity and duration of the current, to avoid symptoms of irritation of the vagus, retardation of the pulse, fainting, etc. In the above described case I had to reduce the morbid excitability of the vagus by producing a state of anelectrotonus, which was followed by cessation of the asthmatic attacks. But in other cases the contrary takes place, the cathode relieves the attack, probably owing to the abnormal reaction of the diseased vagus.

In some cases the exciting cause of the asthma is a congestion and swelling of the nasal mucous membrane; faradic current is then indicated—the anode introduced into the nasal cavity and the cathode applied to the nape of the neck, gradually increasing the current so far as the patient can bear and diminishing it to zero, repeating several times this procedure in one nostril and the same in the other. The treatment should be continued daily until the attacks cease to reappear. Sometimes as after-treatment a mild galvanization of the pneumogastric may be necessary.

Galvanization of the spinal cord is indicated in all its chronic affections. I give here as an instance the method I employ in tabes dorsalis. This disease is generally considered a typical primary systematic affection of the spinal cord (gray degeneration of the posterior columns) and a parasyphilitic disease, *i.e.* it is not genuine syphilis nor is it curable by antisyphilitic treatment, and yet it is alleged that no one can have tabes unless previously affected with syphilis. In spite of these theories it has always seemed to me that the spinal affection was a secondary degeneration in consequence of a primary cerebral affection. This is corroborated by the presence in tabes of various cerebral symptoms: optic atrophy and other ocular troubles, loss of the muscular sense and coördination, whose centers are in the brain, and the occasional combination of tabes with general paralysis of the insane. That syphilis is not an essential integral part of tabes, but only a frequent predisposing cause, is proven by authentic cases of tabes without any inherited or acquired syphilis. Again, were syphilis the cause of tabes, the latter would have been more commonly met with, owing to the prevalence of syphilis. During a scientific expedition in Central Asia in 1857 I was struck with an almost general prevalence of syphilis among the nomadic tribes, and although I had the opportunity to observe many thousands of the native population while studying the immunity from tuberculosis and the effects of kumyss,* I never saw a case of tabes in the steppes of Central Asia.

The tabic process may occasionally originate in the peripheric nerves and extend to the spinal cord (pseudotabes).

I combine the galvanization of the spinal cord with the galvanization of the brain and sometimes treat the peripheric nerves with a faradic brush.

Rev. C. G., over fifty years old, was affected with tabes in its advanced stage, which at first was taken for lead poisoning. He suffered from lancinating pains in the lower extremities and had bladder trouble and constipation; could walk with great difficulty (atactic gait), using two canes; had strabismus, diplopia, and presented the phenomena of Romberg, Westphal, Argyll Robertson.

I treated him, placing a large anode to the lower vertebræ and a cathode of the same size to the nape of the neck, which were kept steadily for several minutes, while the mild galvanic current was gradually increased so far as the patient could bear it comfortably. Then the anode was slowly moved with a certain pressure several times up and down the vertebral column and its sides, the cathode remaining in its place. This was followed by the galvanization of the brain and an application of the faradic brush to the painful parts. The treatment was continued daily, or three times a week, during eight months with very beneficial effect; the pains, which formerly gave way only to morphine injections, entirely disappeared, along with the other troubles. He returned home, could walk comfortably for hours with one cane, rode on horseback and for all practical purposes considered himself well.

The prognosis in locomotor ataxia is favorable in the incipient stage. When more advanced, its further development may be arrested by the galvanic treatment and the patient enabled to attend to his ordinary occupations without suffering, but he could not be considered cured.

In treating cases of tabes I observed an abnormal galvanic reaction of the sensitive nerves. In the normal condition under a mild current and the electrodes of equal dimensions, a slight burning sensation is felt at the cathode only, where it increases with the current intensity, whilst at the anode no sensation is felt, unless the current is strong, and even then the irritation is felt more keenly at the cathode than at the anode. In some morbid conditions, as in tabes, the reaction is reversed—the anode produces the painful sensation, while the cathode is less felt (degenerative reaction of sensitive nerves).* With the improvement of the disease the reaction becomes normal.

*Neuralgia.*—Neuralgias are generally treated with the polar method, the anode being applied to the painful spot, the cathode either to the nape of the neck, or the hypogastric region, or some other distant part, the current flowing steadily for several minutes commencing with a very mild current, which is gradually increased to a moderate intensity, avoiding sudden fluctuations and metallic reversions, and as carefully decreased.

This method is modified according to the exigency of the case. I often use my polar symmetrical method, applying the anode to the painful spot and the indifferent electrode to the corresponding part on the other side. I sometimes combine the local treatment with galvanization of the brain.

When neuralgia is complicated with neuritis the faradic brush allays the pain.

Mrs. C., seventy-three years old, with an organic heart disease, suffered for many years from severe neuralgia of the left trigeminus, including all its branches, especially the second. I began treatment by the usual galvanic method, but soon had to change it in the following way. I introduced a cylindrical positive electrode of a faradic current into the left nostril and a flat negative to the nape of the neck or the left cheek alternately; increased the current intensity so far as the patient would stand it and gradually decreased, repeating the procedure several times during one or two minutes. She felt better after each application and in a fortnight the neuralgia disappeared. I continued the galvanic treatment for another fortnight with mild currents, applying a large pliable anode, covering the painful left side and the cathode to the corresponding right side of the face. The patient

*Neftel: "Beobachtungen aus den Kirghizen Steppen," *Verhandlungen der Physikalisch-Medicinischen Gesellschaft zu Würzburg*, 1859.

Transactions of the International Medical Congress, London, 1881.

**Archiv für Psychiatrie und Nervenkrankheiten*. Bd. XVI, Heft 1.

remained absolutely free from all pain during two years, when, at the World's Fair in Chicago owing to the excessive heat and overexertion, she had a relapse, which, however, yielded promptly to the same treatment.

Mrs. L., sixty-five years old suffered intensely from an aggravated form of sciatica on the right side which for four years interfered with night's rest and affected her general health. On account of the pain the leg was bent in the hip and walking without a cane was impossible. A pliable anode was placed upon the affected sciatic nerve, the cathode to the upper lumbar region. Beginning with a mild galvanic current, it was gradually increased until the burning sensation at the cathode became severe, when it was as carefully decreased to zero. On alternate days the cathode was applied to the hypogastric region, and the anode, now a solid electrode, first to the lumbar region, then slowly moved with a certain pressure along the sciatic nerve, terminating the application on the sore spot. Each treatment lessened the pain and improved the mobility of the hip. At the end of two months the patient was free of pain, walked without a cane and her general health was restored.

Mr. H., forty years old, thin, emaciated—a martyr to sciatica. Three years before he came to me he had broken through the ice, and, drenched to the skin, had to walk a long distance to his home. In consequence of this accident severe sciatica developed on the right side, especially in the sphere of the peroneus, and would not yield to any treatment. I used the polar method with the anode on the affected part and the cathode at the hypogastrium; although the pain became less severe, it showed no tendency to yield any further. I then applied the anode to the right peroneus nerve, the cathode to the left peroneus, which relieved the pain more than any former application. The improvement continued steadily, and when to this treatment I added the galvanization of the symmetrical upper parts of the sciatic nerves, the recovery became complete.

The galvanic treatment is beneficial in other forms of neuralgia, which cannot be described here; but these few illustrations suffice to show that the methods have to be modified according to the peculiarities of each case.

In neuritis the faradic current is indicated.

I have endeavored to show, as far as possible in a single paper, the advantages of employing the electric treatment in general practice with the simplest galvanic and faradic apparatus, and without much loss of time to the general practitioner. The costly, complicated apparatus should be left to the specialist, neuropathologist and electrotherapeutist, for therapeutic purposes and scientific researches. I hope to speak of these on a future occasion.

16 East Forty-eighth Street.

## SUPRAPUBIC LITHOTOMY.*

By J. J. BROWNSON, M.D.,
DUBUQUE, IOWA.

It was in Paris in the year 1745 that the first suprapubic operation for stone was performed by Colot. It is not my purpose to trace the many changes of this operation from its inception to the present time, for like nearly all surgical procedures it has had its advocates and opponents without number.

Vesical calculi are found at all ages, and, for anatomical reasons, are more common in the male than in the female.

It is supposed that stone is caused by some peculiarity in the drinking water, or by some defect in the urinary apparatus, causing a slight precipitate which acts as a nucleus upon which deposits of the urinary salts take place, layer upon layer, finally producing a calculus of varying size, or numerous ones formed from fragments of the original. Of the various types of stone, viz., uric acid, oxalate, and phosphate of calcium, there are several kinds and various methods of development. I need not dwell upon them, as they are familiar to all. Stone in the bladder, when discovered, should be promptly removed, thus preventing various changes in the bladder and kidneys and untold suffering and death.

What symptoms will lead us to suspect stone in the bladder? Patients will usually come complaining of constant desire to make water. They find it necessary to get up frequently at night. There is often pain down the thighs and at the end of the penis. In children a long foreskin and a constant irritation of the organ, should cause us to be on the lookout for other signs of stone.

Any of the above symptoms in patients under thirty, should lead us to investigate. One of the most valuable evidences of this affection is the stopping of the stream of water when once started, to pass again when the position of the body is changed. The passage of blood should also cause us to be suspicious. After all, we can be sure that we have a case of urinary calculus only when we can detect it mechanically by means of an instrument introduced into the bladder.

This is called the operation of sounding. I call it an operation because all the precautions should be taken in performing it. The ordinary searcher or steel sound should be used, one of block tin that may be bent is especially useful. The patient should be told to retain his urine, or if the bladder be empty, a warm solution of boracic acid may be introduced. The instrument, after being sterilized, is anointed with a little olive oil, and passed into the bladder, and a thorough examination made. Gentleness must be the rule in all bladder manipulations, and great care must be taken to keep the patient from getting chilled.

If, after an examination, no stone is found, a rectal bag should be introduced and distended with about six ounces of water. This will raise the bladder up, and in this way I was able to detect a calculus in one case in which repeated examinations had failed to find it. As a final resort when no stone is found, it is well to let the fluid drain away slowly, so that the stone will roll up against the searcher as the last few drops of fluid come away.

It is well to remember that the examiner will not always hear the "click" as described, but more often a roughness will be felt, as if the searcher were passing through sand. It is the most trained tactile sense rather than that of hearing which is most to be depended upon. With every precaution it is sometimes only after repeated examinations that a diagnosis can be verified.

The presence of stone having been determined, what means shall be taken to remove it? There are two methods of removing stone from the bladder; that by crushing, and that by cutting. With crushing methods I have had no experience. It may be that in skilled hands this operation is all that is claimed for it, but I think that for the ordinary surgeon, the cutting operation will yield the best results, as what skill is required he is constantly using, while the performance of lithotry or lithola-paxy requires special practice and special instruments, and these are not to be had by the average surgeon.

*Read at the third anniversary meeting of the Jo Daviess County Medical Society, at Warren, Ill.

Of course the foregoing remarks refer to calculus in the male, since this condition in the female is usually dealt with by dilating the urethra and removing the stone.

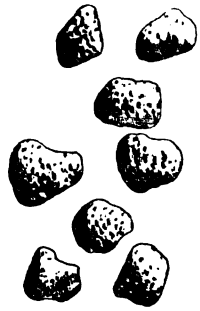
Of the cutting operations there are two, known as the high or suprapubic, and the low or perineal.

I will refer briefly to a few points in which I think the high operation the superior. You all remember the story of the smith at Amsterdam who removed the stone from himself. It was when I heard this story that I made up my mind that this was the anatomical route. The danger from hemorrhage is not so great, and there is no fear of wounding the rectum. We all understand that the perineum has a delicate and peculiar nerve supply, especially in old persons, when great changes have taken place in the tissues. It is a well-known fact that operations on the perineum require a greater amount of anæsthesia than on any other portion of the body, and also that a majority of the deaths from ether and chloroform during surgical operations are those connected with the perineum. These phenomena all show that there is a special susceptibility in this region. On the other hand, the principal objections to the high operation consist in the danger of urinary infiltration and the wounding of the peritoneum. I have always thought that urinary infiltration was a surgical bugbear. I never knew of a case, nor do I see how it could happen if the operation were properly performed.

As to wounding the peritoneum. Suppose it is

No. 1.

No. 3.



No. 2.

wounded, it could be sewn up again. This accident happened in one of my cases, and it had not the slightest effect on the result.

The greatest advantage in the suprapubic method is the ease and thoroughness with which the operator has control of the bladder. Its surface can be explored for multiple encysted calculi, growths, etc., and, if the stone is very large, there is plenty of room for its removal. If it is thought necessary to drain the bladder, better drainage is secured, although this might seem contrary to the fact. I have siphoned the urine out for weeks, without touching the tubes.

Having determined the presence of a stone, and that we will make the high operation for its removal, the principal point to fix in the mind is the suprapubic interval through which we can enter the bladder where it is not covered by peritoneum. It was in 1880 that Professor Peterson of Kiel introduced the idea of distending the bladder and rectum, so as to increase the space, since the distended bladder ascends into the abdomen and through the interval we can safely enter the bladder for the removal of stone or new growths, or for drainage.

The usual preparations, as for laparotomy, are now made, the anæsthesia is administered; when the patient is unconscious the rectal bag is oiled and introduced into the rectum, and distended with six ounces of water, and the end tied to prevent leakage. The catheter is introduced and eight ounces of Thiersch's solution thrown into the bladder, after which the catheter is removed and a tape is tied around the penis to prevent escape of the fluid. It is best to measure these solutions and use the irrigator, and if this is done there will be little danger of rupturing either rectum or bladder.

Before commencing the operation it is well to determine the outline of the bladder by percussion. When the operator has convinced himself of the dulness, he should make an incision about two and one-half inches long above the pubes, going right down in the linea alba until the fat above the bladder is reached. This is pushed up with the finger nail, or the handle of the knife, and then on retracting the edges of the wound the veins over the bladder may be seen. Now the index-finger of the left hand is passed down and the bladder is palpated. The assistant now hooks up a portion of the bladder wall, and the operator, using the finger as a guide, incises the bladder. As this is done the fluid gushes out. The finger is then passed down to the bottom of the bladder and the stone can readily be felt and removed, either by fingers or forceps. It is best not to remove the finger until the stone can be taken out.

After it is made certain that the bladder is clear, the edges are stitched to the wound and a drainage tube put in. The rectal bag being removed, the bladder is now washed out with Thiersch's solution, a gauze dressing is put on, and the patient is removed to bed.

The drainage tube is made by sewing two No. 10 flexible catheters together through the eye, and when they are in place, two siphon tubes of glass are put in the ends and a receptacle placed alongside the bed to catch the urine. If the patient is young and bladder is healthy, an attempt may be made to close the bladder with gut sutures in the usual way, and in that case a catheter should be fastened in the bladder through the urethra. I think, however, when there has been some cystitis it is better to drain.

If the urine does not come through the tubes, they may be washed out. If the urine becomes loaded or cloudy two grains of boracic acid should be given every two hours until the urine clears up. We can leave the tube or catheter in place several weeks by keeping the urine sterilized with boracic acid.

To further illustrate, I desire to report a few clinical cases and show some specimens of urinary calculi successfully removed:

Case I.—J. C., resident of Delhi, aged sixty-nine years, referred to me by Dr. Flower for operation for stone in the bladder. Examination confirmed the diagnosis and he was sent to the Mercy Hospital for operation. The operation of suprapubic lithotomy was done, and the stone (No. 1) extracted. Drainage tubes were put in and after three weeks removed. Although quite an aged man, the patient made a good recovery.

Case II.—Mr. S., came to me suffering for the past two years with urinary trouble. He had been sounded by several physicians, who declared he had no stone. I had him removed to the Finley Hospital, where Dr. Hamilton gave him ether. On introducing the searcher it passed over a roughened surface like a bed of sand. Diagnosis of probable stone, and operation advised. Several days afterward operation suprapubic was made. There were found eight encysted stones (No. 2). The bladder was drained, and, with the exception of considerable difficulty with gas in the bowels, he made a good recovery. The tube was removed on the fourth week.

Case III.—P. G., aged sixty years, resident of Farley, Ia., referred to me by Dr. Lambert for opera

tion for stone in the bladder. Upon examination the characteristic "click" was elicited and the opinion of Dr. L. confirmed. Operation was advised. Accordingly the patient was removed to the Mercy Hospital and suprapubic operation done. On the bladder being opened, the large phosphatic calculus (No. 3) was removed. Owing to the size of the stone the opening in the bladder had to be enlarged. This was easily done and the stone extracted. Drainage was made, and the tube removed in three weeks. Following this the wound closed quickly and the patient was soon well.

## TREATMENT OF CERVICAL ADENITIS DUE TO TONSILLAR INFECTION.

By ALBERT E. ROGERS, M.D.,
BOSTON.

That the tonsils situated as they are between the pillars of the fauces are portals of infection is now a well-established fact. When the gland has been inflamed almost every known pathogenic bacteria have been found in its crypts.

B. Frankel has stated that an infection of the tonsils could take place through inflammatory conditions of the nasal mucous membranes and J. Goodale has demonstrated by a series of experiments that the infection can take place from the fluids of the mouth directly through the mucous membrane of the crypts. According to Ruge, tuberculous infection has taken place, and Jessen reports four cases of pyæmia of varying intensity due to tonsillitis. Mayer is of the opinion that infections take place through the tonsils and are often serious in their sequelæ, and he believes that existing tonsillar disease should be energetically treated and every means should be taken to prevent recurrent attacks.

The cervical glands receive their lymphatics from the tonsils, and these latter being once infected, the extension of the infection to the glands of the neck is an easy step, and it has been a matter of common observation that cervical adenitis in children and young adults is commonly associated with hypertrophy of either the faucial or pharyngeal tonsil. Jessen also emphasizes the fact, and I wish to do the same, that tonsils with a normal appearance may yet contain a hidden focus of infection.

Having an acute tonsillitis to deal with, it is obviously necessary to employ energetic treatment to prevent a cervical adenitis, and I believe that applications of a five-per-cent. aqueous solution of iodine to the crypts is a preferable method to the use of the ordinary antiseptic gargles alone. In acute ulcerative tonsillitis the best treatment is to remove the diseased tonsil tissue by cutting well below the floor of the ulcer and then applying a strong antiseptic to the cut surface.

In the treatment of chronic cervical lymphadenitis Goodale has obtained most excellent results from the injection of a ten-per-cent. aqueous solution of iodine into the tonsillar crypts by means of a hypodermic syringe. He repeated the injection every third or fourth day, and in most of his cases there was a marked reduction in the swelling of the glands.

In my treatment of these cases I have been more radical, and in place of treating the tonsil itself, have resorted to as complete a removal as possible, and I now suggest that in all cases of cervical adenitis, in which the glands have not already broken down, the surgeon should first extirpate the tonsil before resorting to an incision through the skin. Usually an unsightly scar is a result of this latter method of external incision and curetting, and the source of infection remaining in the tonsil, the enlargement of other glands may necessitate still further operation and a more extensive scar.

I append the notes of five cases treated according to my suggestion, and it seems to me they should appeal to those surgeons who are still operating upon cervical adenitis through the skin:

Case I.—A young lady eighteen years of age. Has had the various children's diseases. No tuberculous history. Has had recurrent attacks of tonsillitis. Two months after last attack noticed a swelling at the side of neck. Her physician ordered potassium iodide internally and external applications of iodine vasogen. The swelling gradually grew larger for a period of one year, when operation for removal of the glands was advised. She was referred to me. There was an enlargement of the cervical glands on the left side, causing an unsightly swelling about the size of a hen's egg. The tonsil of the same side was hypertrophied and adherent to the anterior pillar. I advised the extirpation of the tonsil before resorting to the removal of the glands. This was done under ether by means of the tonsillotome and the tonsil punch. Six weeks after the operation the swelling of the glands had disappeared and there has been no recurrence in two years.

Case II.—A girl of six years. Diphtheria when four years of age. An aunt and grandmother with phthisis living in the same house. Cervical glands enlarged on both sides. Tonsils moderately enlarged and a small adenoid present. Removal of the adenoid and tonsils advised and done under ether with the Gottstein curette and tonsil punch. Swelling of glands entirely disappeared six months after operation. No recurrence.

Case III.—A girl ten years of age. Always had been in good health until six years of age when she had an attack of tonsillitis. After the first attack she had many recurrences, and enlargement of the cervical glands appeared at nine years of age. The glands gradually increased in size until, when seen by me, the swelling upon the neck was as large as a goose's egg. There was no tuberculous family history. She had been treated by a number of physicians with iodides, iodine, and other remedies, and was finally referred to a surgeon for removal of the glands.

When I examined her there was no tonsil tissue to be seen on the left side, but there was a marked swelling covered by the united edges of the anterior and posterior faucial pillars (much like a pea in a pod). Under ether the adhesions were separated, and by means of the tonsil punch I removed a large mass of gangrenous tonsil tissue. In two weeks there was a marked diminution in the size of the enlarged cervical glands, but it was nearly six months before they had entirely disappeared. There has been no recurrence one and one-half years after operation.

Case IV.—A girl of twelve years. Poorly nourished. When nine years of age had a "sore throat," which was followed by enlargement of glands on the right side of the neck. About a year later one of the glands broke down and was incised and curetted by her attending physician. It took a very long time to heal. The other glands increased in size until, when I saw her, the general cervical swelling was as large as my clenched hand. The right tonsil was moderately enlarged, very pale and adherent to the anterior pillar. Under ether this tonsil was extirpated with the tonsil punch, and eight months after operation the swelling of the glands had entirely disappeared. This was one year ago and there is no recurrence.

Case V.—Girl, aged eight years. Good family

history. Had always been well. Eight months previous to having been seen by me she had an attack of tonsillitis. This was followed by enlargement of the cervical glands of the right side. She came to the clinic of the Massachussets General Hospital in the service of Dr. J. Payson Clark, to whom I am indebted for the privilege of removing the tonsil before she was referred to the surgeon. The extirpation of the tonsil was done under ether, and the patient reported a week later with only a slight cervical swelling, which at the end of the following week had entirely disappeared.

83 Westland Avenue.

## PERINEAL SECTION FOR STRICTURE, WITH SUGGESTIONS UPON THE USE OF THE CAUTERY, AND POINTS IN THE AFTER-TREATMENT.

By CHARLES C. MILLER, M.D.,
CHICAGO.

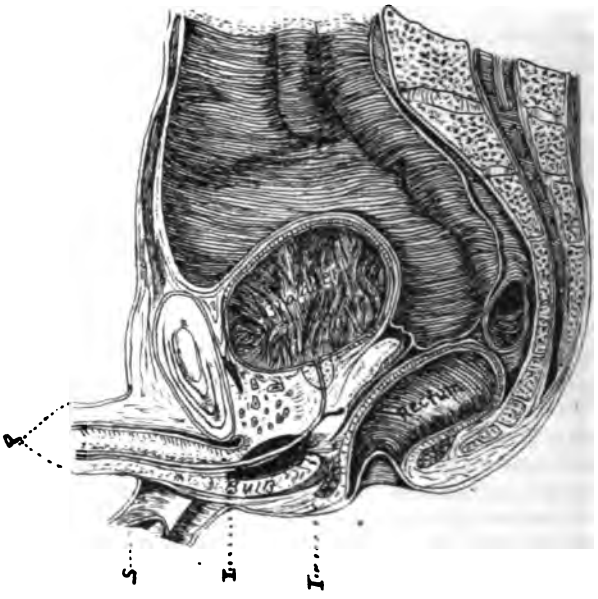
External urethrotomy for the relief of urethral stricture is an operation which causes considerable inconvenience to a patient submitting to it, but as it offers a chance of a permanent cure, many patients are willing to submit to the loss of time which its convalescence entails. Perineal stricture gravely endangers the welfare of its possessor, and operative relief by section of the stricture tissue can be recommended in any case. When the section can be made upon a staff, the operation is an easy one. In order to secure such a condition, as will permit of the passage of a staff prolonged efforts should be made, when necessary, to secure an enlargement of the stricture of small caliber. No better or surer means of doing this can be found, if a filiform can be passed, than by the use of the Maisonneuve urethrotome. Hours may be spent with profit in passing the filiform, which will guide the staff of this instrument. The smallest blade of the Maisonneuve will enlarge the urethra to such a size as to permit of the easy passage of a grooved staff.

With a grooved staff in place, held in a perpendicular position, bulging the perineum in the median line as much as possible, an incision is made from the perineoscrotal juncture to within an inch of the anus. After the incision has been carried down through the tissues, and only the walls of the urethra remain uncut, it is well to palpate if possible the stricture tissue. The urethra is then opened by carrying the knife along the groove in the staff, and the cicatricial tissue in the floor of the urethra completely divided. In some cases, when the finger cannot locate the stricture, we are made conscious of its presence by the increased resistance which it offers to the knife. The staff can now be removed. With the free skin incision it is not necessary to catch the cut edges of the urethra with forceps or take a stitch on each side, as retraction of the superficial parts will give good access to the urethra.

The roof of the urethra is now to be palpated, and if the stricture tissue can be located, it is to be divided by a cut along the roof. If the Maisonneuve instrument has been used in the beginning of the operation, the cut which its blade made along the roof can be found and enlarged until all fibers of the stricture have been divided. The Paquelin cautery is now brought into use. It should be at a dull red heat. It is carried to the bottom of the wound in the roof of the urethra, and one surface of this wound rapidly streaked by the lateral margin of the heated tip. If the wound is bleeding rather freely the opposite surface may also be cauterized for purposes of hæmostasis, but hæmostasis is not the object of our use of the cautery.

The cautery is now carried along the margin of the incision into the floor of the urethra. An area from one-eighth to one-quarter of an inch broad is to be cauterized by a single rapid stroke. This cauterization extends the entire length of the incision into the urethra.

The use of the cautery is to insure the formation of granulations, and thus prevent primary union taking place. One object in dividing a stricture is, if possible, to secure an alteration in the nutrition of the tissue so that absorption may occur, or a metamorphosis take place, and thus further trouble from the condition be prevented. Even if such fail to occur, we hope to establish a condition which will give relief in another way. By our incision we separate the urethral floor and roof, and we hope to leave a surface which will granulate and then be covered by epithelial cells from the margin of the urethra, so as virtually to add to the caliber of the urethra at this point.



The urethra has been opened by an ordinary median incision extending between dotted lines I. I. By this section the stricture has been cut through below along the floor of the urethra. By palpation stricture tissue is carefully felt for along the roof of the urethra, and, if found, it is divided by a cut running parallel to the urethra. When the Maisonneuve urethrotome has been used to pave the way for a staff, the cut which it has made is to be found and deepened if necessary, so that the stricture is completely divided. The cautery is then brought into use, and one lateral surface of the cut in the roof of the urethra is quickly cauterised. Then the same procedure is repeated along one side of the cut in the urethral floor, the width of the strip cauterised along the floor varying from an eighth to a quarter of an inch.

In this way subsequent contraction will not at once diminish the caliber of the urethra below the normal.

In the absence of constant irritation and inflammation cicatricial tissue has a tendency to contract only to a certain extent. In urethral stricture contraction is progressive, because in so many cases there is a constant irritation and inflammation of the mucosa and deeper tissues. In other cases we have this constant urethral and periurethral inflammation coupled with minute capillary urinary extravasations, which help to keep up a continual production of connective tissue. These conditions being overcome by our operation, we shall have a certain amount of contraction of the connective tissue, which necessarily follows our operation, but even after it is completed, the lumen of the urethra will be as great or greater than the normal. In this way there will be no inflammation re-excited by the obstruction to the outflow of urine.

The cautery must not be too hot nor allowed to

rest against the tissues too long, as it may be followed by sloughing of the tissues.

Before the operation is completed we must make sure that the entire urethra is free from any contractions. This can be ascertained by a full-sized sound. The urethra should be distended to its normal limit. More harm will result from failure to use a large enough instrument than from any other one thing. It will be seldom that an instrument as small as No. 30 French will be called for.

A soft rubber catheter of a size not greater than a No. 22 French is now passed into the bladder through the perineal wound. The bladder is then to be filled with fluid by means of an ordinary irrigator, and the fluid allowed to flow out of the catheter. As the solution flows from the catheter it is withdrawn from the bladder until the flow ceases. This will show that it is no longer in the bladder. Now it is again pushed slowly toward the bladder until the flow recommences. This will show that it is just within the bladder. A stitch with silkworm gut is now to be taken through skin and catheter so as to hold the instrument in the lower angle of the wound. As fast as the urine forms, it will flow through the catheter, which is attached to a tubing so as to conduct the solution into a vessel at the side of the bed.

The remainder of the incision is to be closed with silkworm gut. These sutures should not extend deeper than the cauterized area. During the time when the incision was being made into the urethra all bleeding points were caught with hæmostats. These are to be removed at the end of the operation, and if any points bleed they are to be tied with fine catgut.

Constant drainage is used by some for several days after the operation, but I find it much more pleasant to the patient to remove the catheter as soon as he has recovered fully from the anæsthetic. In rare instances only, when there is an indication for complete rest of the bladder, the tube can be left in for some time.

In order that the wound may not be infected or contaminated with the urine, I order the patient to be catheterized through the perineum every six hours in those cases in which the bladder is infected. This is kept up for three days, and is, I believe, a most valuable method of treating these cases. The wound will in this way remain perfectly sweet and clean, and the case will run a non-febrile course. After the third day union of the surfaces which were not cauterized will have commenced, and the contact of the urine will do no harm. The catheter can be used with less pain than the urine would excite, and the patient does not suffer from the pain and inconvenience of a retained catheter.

In conducting an operation upon the perineum, we must keep in mind the fact that we are going to catheterize these patients subsequently, and also that a sound must be passed every few days in the after-treatment. For this reason, particular care must be exercised in the dissection we make posteriorly. In the perineum it is often necessary to get one's bearing. In so doing we must make any dissection that is necessary in the anterior portion of the wound. The posterior portion of the wound must be a clean regular cut. A chopped-up condition of the tissues here will almost invariably complicate the after-treatment. When an attempt is made to sound such a patient, the instrument will spring off into one of the irregular pouches or sulci so formed; this will mean failure to reach the bladder, and much suffering to the patient. I have seen more than one unsuccessful attempt made to pass a sound after an operation by an operator of international reputation.

The selection of the sound will have an important bearing upon the success of the after-treatment. It should be a large one, as it is our object to secure a urethra for the time being larger than normal. The instrument should also be one with a short beak and a slight curve. The Van Buren instrument is an exceedingly poor one. The beak is too long and the curve too great. The natural tendency of this instrument is to spring off to one side in any urethra. This is due to the fact that it follows too closely the roof of the urethra. This principle of following the roof of the urethra is not to be condemned, but the instrument exercises so much pressure along the roof in the deeper portion of the urethra, that its natural tendency is to rotate. This it will do if left to its own inclination. In the urethra after the perineal section this tendency is even more decided. In spite of the effort of the surgeon it will slip off to the side into an interstice, and it will refuse to enter the bladder. Such difficulties will cause very great pain to the patient.

This tendency can be seen when a student with little experience is using a sound. He has been taught to "allow the sound to take its own course," and in following the instructions he invariably allows the instrument to rotate. I have had students in my clinics who would allow the sound to rotate completely merely from following this rule. A majority of students will fail to find the entrance to the membranous urethra, when they make their first effort to pass a Van Buren sound.

Such difficulties will not be met with if a sound is used with a short beak and a much slighter curve than the Van Buren. Such an instrument can be made to follow the roof of the urethra, but of its own accord does not do so to too great an extent.

100 State Street.

## FOREIGN BODIES IN RECTUM, WITH REPORT OF TWO CASES.

By MAURICE ROSENBERG,
NEW YORK.
ATTENDING PHYSICIAN TO BETH ISRAEL HOSPITAL DISPENSARY, CHILDREN'S SERVICE.

In looking over various authorities on rectal ailments, I failed to find the subject of foreign bodies in the rectum treated. The anatomical structure of the rectum is such as easily to allow the retention of a foreign body in the crypts immediately within the external sphincter as well as above the upper border of the sphincter, in the semilunar valves, and in the rectal ampulla. My intention is to show by two cases which came under my care simultaneously the necessity of looking for foreign bodies in the rectum if only for their exclusion in our diagnoses.

Case I.—Mrs. H. O., a woman, aged forty-three years, mother of eight children, menses regular, was in good health until four weeks before she consulted me. She then experienced a sudden sharp pain in the lower sacral region, penetrating to the region of her bladder, together with a desire to defecate. This she attempted to do, but there seemed to have set in a tenesmus of the anus, and she moved the bowel only after the use of an enema; the pain then subsided, and she thought no more of it until the next day when there was a repetition of the attack, of which she relieved herself as before. She then consulted a physician who diagnosed the case as one of anal fissure, and treated the patient

with local applications for a week without relief. He then advised a consultation with a surgeon, who confirmed his diagnosis, and after a thorough rectal and vaginal examination recommended dilatation of the anal sphincter. The patient submitted to this treatment for ten days, during which time she became actually sick, being confined to bed, and the sharp attacks of pain came more often and continued longer. She then went to the outdoor department of a hospital and was told that she was suffering from internal hemorrhoids, and was advised to enter the hospital for radical treatment. She promised to come the next day. I saw her the same night, she having been recommended by a patient whom I had treated for ischiorectal abscess, and who told her that "he had suffered the same way."

When I saw Mrs. O. she was in bed, appeared suffering greatly, continually complaining of pain in her rectum and lower part of the back and abdomen, expressing a continual desire to defecate, even after the bowels had been washed out, which was then being done twice a day. At first sight she looked like a person suffering from a malignant neoplasm of the rectum or generative organs—she was so emaciated. After making a thorough examination of her generative organs with a negative result, I everted the rectum by pressure on the posterior vaginal wall and was surprised to see two fish bones lying lengthwise in the folds of the mucous membrane of the rectal ampulla, and which I had no difficulty in removing. The relief was instantaneous, and after treatment for a few days the normal action of the bowels was restored, and the patient made an uneventful recovery.

About a week after having finished treatment on this case, I was called to see

CASE II.—Benjamin K., aged sixteen months, who had since the day before been crying incessantly, especially when he passed water or the bowels moved. I examined his genitals, which were normal; there were no signs of eczema or local irritation in the region, and no seat worms. On stretching apart the sphincter ani a scale of a fish was exposed, lodged in the crypt of the anal opening, just within the mucocutaneous border, and which the mother removed as I held the parts on the stretch. I had no occasion to see this baby again and suppose this ended the child's sufferings.

141 BROOME STREET

---

**A Case of Malignant Œdema.**—A. H. Gould describes a case in which diagnosis was verified by bacteriological tests, which, with findings, are described in full. His patient was an Italian adult laborer, who had a lacerated wound of the right heel which was sutured, but in two days it became septic. Swelling gradually crept up the leg, and the glands in Scarpa's triangle became enlarged but not tender. The posterior aspect of the right heel was covered by an irregular black eschar, occupying an area three inches long by two inches wide. In the middle of the diseased area was found a lacerated opening, through which exuded foul-smelling, bloody pus. No redness or œdema were present below the ankle-joint or on the dorsum of the foot. Above the ankle for six to eight inches along the back of the leg, redness, induration, and œdema were noted, while crepitation could be plainly felt about the ankle itself. The man refused operation; the emphysema extended up the leg to within two inches of the tuberosity of the tibia, in front, and to within three inches of the popliteal space, behind. The posterior aspect of the leg was black and mottled, while the anterior aspect was covered with yellow and blue streaks. The œdema extended over the ankle and the dorsum of the foot. Amputation of the limb was performed at the knee-joint, and the patient recovered, though a pneumonia supervened on the twenty-fourth day.—*Annals of Surgery.*

**The Differential Diagnosis of Conjunctivitis and Iritis.**—George J. Lund says that the mistake has been made of diagnosing a case of iritis as conjunctivitis with disastrous results to the patient, the treatment used for conjunctival catarrh being sure to increase the iritis. We should examine carefully for a milk zone of ciliary infection, a discolored iris, a small pupil, and a slightly milky aqueous, with resulting reduction of vision. The pain of iritis is usually of a pronounced neuralgia character, and often worse at night. Photophobia ciliary injection and increased lachrymation accompany the inflammation of the iris. The pupil is contracted and does not react to light or shade. Exudation takes place to some extent in all cases of iritis. The plastic material causes the iris to thicken as well as changes its color and binds its pupillary border down to the lens. The aqueous early becomes turbid through the presence of the exudate, and the vision at once is foggy and reduced. Sometimes dots of exudate appear on the posterior surface of the cornea, or the material may settle to the bottom of the anterior chamber, where it forms a hypopyon.—*Southern California Practitioner.*

**A New Method of Performing Perineal Section without a Guide.**—C. L. Gibson thus describes his method: Lithotomy position. Thorough preliminary irrigation and cleansing of the rectum. A suitable speculum, preferably Kelly's, is introduced, and the prostate is *transfixed* laterally from the rectum, preferably by a large, sharp hook, which is driven firmly through the prostate tissue. The speculum is now withdrawn, leaving the hook *in situ*. Median perineal section is then performed, the incision being extended down to the ordinary depth of the situation of the urethra. The left forefinger is now introduced into the wound. As the assistant executes a series of gentle tugs on the hook, one readily receives the sensation of the intermittent tension of the urethra in response to the traction on the prostate. Keeping the forefinger in place, the surgeon (with the other hand, *not* as erroneously depicted) directs his bistoury into that portion of the deep urethra which is thus rendered prominent; the probe-pointed director readily glides alongside the knife into the lumen of the urethra, and following it the small metal catheter will demonstrate the successful access to the bladder. The performance of these various steps requires only a minute or two.—*Annals of Surgery.*

**Tropical Abscess of the Liver.**—E. F. Robinson refers to fourteen cases seen in the Philippine Army Service, and gives the histories of six in full. He regards dysentery as the cause, but the part played by the amœba coli is undetermined. All but one of his cases were of dysenteric origin. Five were single and nine were multiple abscesses. Concerning symptoms, he notes that pain of a sharp, stabbing character in the right side, radiating upward into the right shoulder and usually localized beneath the scapula, is of common occurrence. Added to this an irregular temperature, which later tends to become hectic, and early a rapid pulse, mark the beginning of septic infection. Persistent pain over the region of the whole liver, with a point of local tenderness just below the margin of the rib in the anterior axillary line, is usually present. Local signs of abscess formation (redness and œdema, with bulging and increase in the width of the interspaces of the right side) do not generally appear until late in the course of the disease, depending upon the distance of the abscess from the surface. Great increase in the area of liver-dulness not only above and below, but partially to the left of the median line, was found in all his cases. The local and general symptoms may develop from a patch of necrosis without pus formation. In discussing treatment, he notes the inefficiency of gauze drainage. Double tubes of non-collapsible rubber should be used with normal salt solution or sterile water for irrigation. Strong antiseptics are dangerous.—*Annals of Surgery.*

## THE ETIOLOGY AND PATHOLOGY OF VARIOLA.

THE *Journal of Medical Research* for October contains three articles by R. G. Perkins and G. O. Pay on this subject. Previous work seemed to have left little possibility that the cause was any microorganism similar to the usual forms of bacteria, while other observations appeared to indicate that it was not infravisible. The best place to look for it appeared to be in the exudate, especially in the earlier stages, and perhaps also in the circulating blood. Dombrowski, Funck, and Ishigami have described sporozoan organisms, which they refer to the Sporozoa, but the resemblance ends there. The authors found some of the bodies described by each of the observers mentioned, but the most exhaustive study convinced them that they are not organisms but rather various forms of cell degeneration. In particular, with regard to the diplococcoid bodies described by Pfeiffer and emphasized by Dombrowski, all the facts observed tended to point to the so-called sporozoites being fatty degeneration products of the cells. The mononucleosis in the blood, observed by several investigators, was a conspicuous feature. The increase seemed to be principally in the large mononuclears. With the eosin-methylene blue stain, polychromatophilia was a marked feature. In no case, however, were any bodies which suggested amœboid forms, found in the blood. Cultures in collodion sacs incubated in the peritoneal cavity of rabbits were invariably negative. The medium remained unclouded, and exhaustive examination revealed nothing they could claim as parasites. Attempts to obtain cultures in the aqueous of the eye also failed. The authors add that the undoubted fact that the contents of the vesicles and pustules are infectious, and must, therefore, have within them some form of the organism to which the disease is due; the evidence that this organism is of such a size as to be held back by the pores of a filter which does not restrain organisms we are able to see; and the fact that, in spite of protracted endeavors, they have been unable to see anything in this material which they could conscientiously say to be parasitic, leads Perkins and Pay to the conclusion that the organism must be present in some form which, at least by the methods at their disposal, is not to be differentiated from the cellular débris which is so conspicuous in the field. This at once suggests looking farther back, and it seems to them that their work, in so far as it leads to this suggestion, is confirmatory of the recent paper of Councilman, who finds his organisms in recognizable form only in the very early stages of the variolous lesion. According to his ideas, all that there is in the vesicles and pustules, free in the fluid, is the spore stage, and inasmuch as these spores are said to be only one to two microns in size, they would be almost impossible to distinguish from the débris without some special stain.

The lesions found in the forty-five autopsies were simply those occurring in any acute infectious disease. The epithelium of the internal organs, except such epithelium that is a direct continuation of the skin surface, seems not to be selected by the microorganism for its classical manifestations, and, except in the respiratory tract, it was rare to find pocks. The lungs showed congestion and œdema in all cases. In over thirty cases well-marked bronchitis was present. When death occurred comparatively early, the mucous membrane of the bronchi (even of those no larger in diameter than a slate pencil) showed distinct round, or oval areas, more or less sharply defined, with a red areola, and resembling exactly the areas seen in the larynx and trachea, of which they were apparently the continuation, and which they resembled histologically. The involvement of the deep respiratory tract seems to occur very early, for in many cases the skin lesions were far less advanced than those in the trachea. It is partly on this seeming early injury to the bronchi that the authors base their conclusions that the portal of entry for the associated streptococcus infection is probably the lungs. The larynx and trachea were involved in thirty-three cases. Most of the larynges showed distinct ulcerations, which, in the earlier stages, were sharp cut and definite like the pocks on the skin. The trachea, as a rule, was not so extensively involved as the larynx, and the lesions were more often separate and typical.

Regarding the rôle played by the streptococci, the authors conclude that these organisms are present in all or nearly all severe cases which prove fatal, and in many which recover. They may occur in the blood some days, or only a few hours before death, and after death may multiply very rapidly. They bear no relation to the etiology of variola or the pustulation of the skin. Those found in the blood and in the secondary infections vary markedly in constant characteristics. Probably on account of this, antistreptococcic serum prepared from one variety of streptococcus is of no special value against symptoms and sequelæ due to streptococci. The probable portal of entry for the streptococci is the bronchial mucous membrane.

In respect to the changes in the composition of the blood, the authors find that in persons dying from variolous infection, if death occur in the first five or six days the blood shows practically no loss of complement. Later, in the full pustular stage, there is a loss of complement, in general proportional to the extent of skin involved. In those dying after the disappearance of all symptoms directly attributable to variola, death being due to the long-continued suppuration of secondary abscesses, the loss of complement is fairly uniform, and probably of similar origin with that described in wasting diseases. In light cases, taken early or late, there is apparently no loss. Apparently the loss of

complement has very little to do with the secondary streptococcus infections, but that, on the other hand, these infections, if sufficiently long continued, may lead to a very definite loss.

## THE DISPENSARY PROBLEM IN PHILADELPHIA.

THE poor are always with us, and in the large cities of the civilized world so also is the dispensary. Unfortunately, wherever an institution of this kind exists, there appears to be a problem connected with it, and always very difficult to solve. The manner in which dispensaries are conducted and abused is a well-worn subject, but with the lapse of years there is no corresponding cessation of discussion of the matter, and therefore it may be presumed that they are still far from perfect.

Mr. F. B. Kirkbride of Philadelphia has recently published a report made to the Hospital Association of Philadelphia, October 28, 1903, on the dispensary problem in that city. The Hospital Association of Philadelphia appointed a committee—of which Mr. Kirkbride was chairman—on dispensaries and dispensary practice in the spring of the present year, for the purpose of examining into existing conditions in Philadelphia. In order to obtain the necessary data, letters were sent to 481 physicians of the city, requesting that they furnish all the information regarding dispensaries and dispensary practice, within their power. Superintendents were also asked to give particulars as to the scope and work of institutions under their control. The reports of the Board of Public Charities of Philadelphia have also been utilized, so that the information acquired is as full and comprehensive as could be desired.

The report of the committee deals with 61 dispensaries. In 42 of these 61 dispensaries 305,980 patients were treated during 1902, or 238 cases for each 1,000 of the population. In New York 876,070 patients were treated during 1900, or 254 for each 1,000 of the population. Of the Philadelphia dispensaries 39 are connected with hospitals, while 22 treat walking cases only. Of the 61 dispensaries 45 are for the treatment of men, women, and children, while the remainder are special in their character. Forty of the dispensaries are for the treatment of all diseases, while the remainder treat only a special class of diseases.

Of the 61 superintendents of whom information was requested, 39 sent replies. These reports show, in a general way, existing conditions in Philadelphia dispensaries to be as follows: The dispensaries are housed in small quarters, considering the large amount of work which they do. The average number of rooms occupied is 6; the largest number, 17; while the average number of patients treated is 7,285. The average number of physicians connected with each dispensary is 22. These physicians with but one or two exceptions, receive no compensation, except the indirect gain which results from dispensary work.

The answers to the questions concerning dispensary attendance, reveal the fact that the methods now used for recording dispensary attendance, are not only lacking in uniformity, but emphasize the necessity for a more intelligent system. A large proportion of the dispensaries dispense their own medicines, but the charges for the same are not at all uniform. With regard to the cost to the dispensary of each out-patient treated, owing to the want of method in the several institutions, the figures supplied are more or less guesswork; they range from $1.32½ to one-half cent for each patient.

The report rightly dwells upon the question of accounting as a most important one, and states that much could be done to stop waste and secure efficient and economical management were the books of the Philadelphia hospitals so kept that the actual figures for the in- and out-patient departments could be separately determined.

In only eighteen of the dispensaries is any attempt made to prevent imposition by patients able to pay, and of these the larger number try to effect this object by simply questioning the patient.

The report concludes, from a careful study of the superintendents, answers that each dispensary is in a large measure a law to itself, and that there is the greatest diversity not only in the method of handling cases, but in the rules governing the dispensary physicians and in the system of accounting. As might be imagined, the physicians of Philadelphia are to a great extent agreed that the chief abuse of the dispensary is that patients are treated who are able to pay a physician. Some members of the medical profession in Philadelphia declaim loudly against dispensary treatment, mentioning as its obvious abuse that patients are not carefully treated. The report concludes, from a careful scrutiny of the answers received, that while the chief abuse is the application for treatment by those who can afford to pay, the management of these institutions and the physicians connected with them are also open to criticism.

With regard to remedies proposed, physicians show more diversity of opinion than with respect to abuses. The majority think that dispensary cards should only be issued after some form of investigation; that dispensary cases should be used for teaching purposes; and that legal measures should be taken for the regulation of dispensary practice.

The report sums up in part as follows: "A survey of the situation in Philadelphia leads to the conclusion that an unnecessarily large amount of dispensary work is being done in this city. At an average cost of 44 cents per patient, which is probably below rather than above the mark, an annual expenditure of $134,000 is indicated. The unequal distribution of dispensaries. Competition and overlapping of their work all contribute to this result. The desire of the dispensary physician to see his service grow more rapidly than that of his colleagues, either in the same dispensary or elsewhere, is doubtless an important factor." Reference is also made to the fact that dispensary cases are so little used for teaching purposes.

Philadelphia, so far as her dispensary system is concerned, is in a somewhat similar position to that of other large American cities. The dispensary is everywhere abused to a greater or less extent by those able to pay. The physician, too, is doubtless not altogether blameless in the matter, and is perhaps, on occasions, somewhat too keen in making money, notably in referring dispensary cases to his own office.

The committee is of the opinion that direct com-

pensation for services rendered by the dispensary physician would be a long step in the right direction and pave the way for other necessary reforms, and also questions whether it would not be a wise move to adopt legal enactment somewhat in the form of the New York law in the State of Pennsylvania.

## QUARANTINE WORK IN THE PHILIPPINE ISLANDS.

Captain V. G. Heiser, United States Public Health and Marine Hospital Service, chief quarantine officer for the Philippine Islands, has recently published his annual report of the quarantine service in the archipelago, for the year ended July 31, last.

The *Manila Cable News*, September 20, contains a large part of the report—in fact, all its most interesting features.

With regard to cholera, Captain Heiser states that sixty-eight vessels with cholera on board arrived at the port of Manila during the period under review, and cholera occurred on board thirty-seven vessels during the time they were serving their outgoing quarantine. There were thus one hundred and five vessels disinfected for cholera. The report highly praises quarantine system and says, "It is a matter for congratulation that the practice prescribed by the Quarantine Laws and Regulations has been so thoroughly vindicated by practical experience. Of the one hundred and five cholera-infected vessels that were disinfected at the Manila station only one developed the disease after being released from quarantine, and then nine days after disinfection."

Captain Heiser contends that in cholera epidemics quarantine for all vessels is a necessity. He argues that if cholera can spread—as it has spread—on a modern troop ship, where every possible provision is made for stamping out infection, and on which are medical officers who have had special training, then the case in favor of quarantine must be considered proven. Statistics as to cholera in the Philippine Islands are as follows: From the commencement of the epidemic, March 18, 1902, until the ending of the fiscal year, 1903, there have been reported 138,639 cases, with 88,761 deaths, giving a death rate of 63 per cent. The report goes on to say: "A conservative estimate made by medical men of large experience in the islands place the estimate at at least one additional case for every one that was reported, which would make, in round numbers, about 300,000 cases."

Captain Heiser especially emphasizes in his report the great value of quarantining as a means of checking the dissemination of contagious diseases, and points out that with the possible exception of the work done at Tor, Egypt, there is probably more disinfection accomplished at the Mariveles Quarantine Station than at any other plant in the world.

High praise is due to the officers of the United States Public Health and Marine Hospital Service stationed in the Philippines, for the successful manner in which they have performed the arduous duties which have fallen to their lot. In addition to the quarantine work, the service has conducted the physical examinations of masters, pilots, patrons, and engineers; and also of the men who have entered the Coast Guard Service.

Referring to the bubonic plague, the report states that notwithstanding the fact that plague has been epidemic at Hongkong and Amoy, and present at other ports in those countries, not a single case of this disease could be traced to infection from without. This result speaks volumes for the vigilance and energy shown by the officers on duty in China and Japan. The efforts, too, put forth by the Board of Health and by the Public Health and Marine Hospital Service, acting in coöperation, were successful in confining the plague to Manila.

In addition to the vessels disinfected on account of the presence of cholera, two hundred and seven vessels were fumigated with sulphur, seven smallpox and two plague-infected vessels were disinfected, and there were besides one hundred and nineteen vessels disinfected because they came from infected ports. The report of the United States Public Health and Marine Hospital Service, with regard to the work done by its members stationed at Manila, affords striking testimony to the thoroughness with which American officials carry out their duties. There is every reason to predict that the sanitary regeneration of Manila will be as complete as that of Havana and other towns in Cuba.

## The Handkerchief as a Disease Disseminator.

The *New York Times* gives a very graphic account of a meeting of the National Woman's Christian Temperance Union, held last week in Cincinnati, in which the subject of handkerchief-shaking as a method of salute was warmly discussed from its hygienic standpoint.

One of the speakers was welcomed with the customary flutter of handkerchiefs throughout the auditorium, a compliment which she accepted with proper satisfaction, but later in the day an inconveniently practical and learned delegate, Miss Marie Brehm of Illinois, created something of a sensation by declaring that this "handkerchief salute" was a most unhygienic performance, indulgence in which was quite sufficient to account for the wide distribution of colds to be noted among those attending the convention. Miss Brehm therefore moved that the delegates, like sensible people, keep their handkerchiefs in their pockets, where they belonged, except when in necessary use, and that the saluting be done with little silk flags provided for the purpose. This proposition was very ill-received by some of those present, and they argued against it at length and with vivacity, incidentally making a few sharp digs at the composition of the Cincinnati atmosphere, but when the question was finally put common sense and faith in the microbe theory prevailed, and the motion was carried by a vote of 134 to 91. Whether or not it binds all members of the organization everywhere we do not know, but the matter is one of some importance and worthy of general consideration.

It is in fact a grave sanitary question whether the handkerchief does not do more harm than good as it is ordinarily used. When we assume that the healthy nose does not need to be wiped we face a reasonably broad proposition as to the danger of the handkerchief as a disease propagator. Most nasal catarrhs are of an infectious character, notably those of grip origin.

Contrary to a general law of asepsis, the handkerchief saturated with disease germs, instead of being promptly washed, is stowed for hours in the pocket, with a result that can be easily imagined. Is it any wonder then that catarrhs are constantly fostered by a system of autoinfection. Even when the discharges become dried upon this dangerous

article of the toilet, its mere handling or use by others, must necessarily be a means of conveying infection. Worse than the nasal discharges are the expectorations which so often thus find their way into the pocket. The good woman in the convention certainly deserves great credit for drawing attention to the dangers of the handkerchief.

### Views on the Etiology of Tuberculosis.

Professor Hueppe of Prague delivered the Harben lectures in London in October last. The lecturer's reputation for originality and knowledge invest all his remarks with weight. Perhaps the most interesting of the three lectures was that which dealt with tuberculosis, especially as he reviewed and discussed the opinions of Koch with regard to the intercommunicability of human and bovine tuberculosis. Hueppe ranges himself among the opponents of Koch, so far as this matter is concerned, on the grounds that different races of cattle had been found to possess different predispositions to infection, and that numerous investigators had succeeded in infecting cattle with bacilli of human origin. He was, therefore, of the opinion that human and bovine bacilli must be regarded as but varieties of one species of microorganism. These varieties might show morphological differences and necessarily, in consequence of adaptation, they would show differences of virulence when obtained from the bodies of different species of animals. The lecturer pointed out that opinion with regard to the mode of infection had undergone a change since Koch claimed that pulmonary tuberculosis indicated that the port of entry for the bacilli was through the respiratory passages. Professor Hueppe himself, as well as other observers, had shown that pulmonary infection might also follow when the bacilli entered the lungs through the lymphatic and blood circulation, and Grawitz had demonstrated the possibility of infection through the tonsils. Further experiments made in Hueppe's laboratory showed that if rabbits were fed with tuberculous material some developed intestinal and others pulmonary tuberculosis. A special susceptibility of certain organs appeared to determine which organs should be affected. Professor Hueppe held the view that the locus minoris resistentiæ was to be found in the lungs of the adult and in the intestine in childhood.

The lecturer was severe on those bacteriologists who denied the existence of a predisposition to tuberculosis, and said "their views were based on laboratory experiments where large numbers of bacilli were introduced into the body, this in a manner which never took place in natural infection.

"That a specific inherited predisposition existed, was indicated by the fact that in certain families the children became tuberculous in succession on attaining a certain age. In some cases the parts attacked were often the same in the different members of a family."

The pronouncement of Koch's views with regard to human and bovine tuberculosis has at least done good in one respect. Investigators have been incited thereby to redouble their efforts to discover the relation which human tuberculosis bears to bovine tuberculosis. It appears now as if the pendulum were swinging in the direction of the belief that human and bovine tuberculosis are intercommunicable. It would seem that the gastro-intestinal canal of children is more often affected by the disease than has been supposed, undoubtedly owing to the fact that this organ in the young is more permeable than in adult life. It has already been demonstrated in a sufficiently forcible manner that every precaution should be taken to ensure a pure milk supply, for if this be not done there is every probability that intestinal tuberculosis will increase.

### The Menace of the Isthmian Canal.

Now that it is practically decided that a canal, to divide the continents of North and South America, will be built, it may not be out of place to consider the probable effects of this undertaking from a sanitary point of view. In the first instance, it would seem certain that the building of an Isthmian canal will be attended by great loss of life, unless measures are enforced to render the conditions in the regions through which the waterway must pass less inimical to health than is the case at present. The district bordering on the proposed Panama route is, perhaps, one of the most notoriously unhealthy in the world. This fact was conclusively proved by the mortality and sickness among the laborers on the portion of the Panama Canal built by the Lesseps Company. White men were unable to live for any length of time in the locality, and the mortality among the Chinese, and to a lesser extent among the negroes, was frightful.

Sir Patrick Manson, in a paper read before the Epidemiological Society of Great Britain, February 25 of this year, and to which reference has already been made in the Medical Record, foreshadowed the possible danger of invasion by yellow fever of Asia as the consequence of the digging of the Panama Canal. He pointed out that shiploads of laborers would soon be plying between Panama and the seaports of Asia, and that unless extraordinary precautions were taken the inevitable result must be that the malady would be conveyed and spread among the seething multitudes of the Far East. In the *Journal of Tropical Medicine*, August 15, 1903, Dr. St. George Gray, Sierra Leone, returns to this subject, and discusses the sanitary measures necessary to prevent the introduction of yellow fever into Asia from Panama. He is of the opinion that these may be divided into (*a*) measures to be adopted at the point of departure, *i.e.* at the Central American port, and (*b*) measures to be adopted at the port of arrival—the Asiatic port.

The writer takes it as absolutely proven that mosquitos are the sole cause of yellow fever, and suggests that an international sanitary board should be appointed by the governments having interests in the Far East, and that they should be especially qualified for the work. They should have powers to frame such quarantine or other regulations as may be deemed necessary, and to enforce these regulations by means of penalties which should be sufficiently heavy to ensure their being carried out by the most careless and indifferent of captains. The Sanitary Board should make sure that no vessels which have not been thoroughly cleared of mosquitos leaves the isthmus for any Asiatic port. The final clearing of mosquitos should take place at an anchorage to be selected for the purpose at least 300 yards away from the nearest shore, and once the fumigation is completed the vessel should not approach the shore again, but passengers, mails, and cargo from open lighters could be received aboard.

As a further precaution Dr. Gray suggests that any vessel sailing from an infected Central American port other than Panama for an Asiatic port should be obliged to call at the fumigating station at Panama to be cleared of mosquitos ere proceeding on her trans-Pacific voyage. The writer's last

suggestion, however, is most to the point. He says that the most efficient mode of preventing yellow fever from reaching Asia would be to stamp out the disease in Panama as it has been done in Havana. As soon as the decision is made to build the canal, steps might be set afoot to free the selected route from disease as far as it is within the power of man to do so. American sanitarians have already demonstrated their ability in Cuba and in the Philippine Islands, and there is no doubt that if energetic measures be taken that the country through which the great canal will run can be as effectively cleaned as these islands. It is definitely known how yellow fever is spread, consequently its extinction is rendered much less difficult, and the sanitary regeneration of Panama should now be in sight.

### The Cocaine Habit among the Negroes of the South.

Reference has been made frequently of late to the increase of the drug habit in the United States and in the civilized world generally. Cocaine is consumed throughout America much more largely than ever before, and the statement has been recently made on good authority that the cocaine habit has gained a strong hold on the young negroes of the South. The manner in which these people have acquired the pernicious habit, is said to have been when working in industrial establishments in Pittsburg, where nearly all the negroes of both sexes take the drug, and those who return to the South teach those who have remained there to use it. The evil effects following this practice among negroes in certain parts of Virginia have become so notorious, that in the city of Staunton the judge of the Corporation Court, a short time ago, gave the matter in a charge to the grand jury for investigation.

The result of the investigation has clearly shown that the gravity of the situation as regards the cocaine habit among the young negroes had been in nowise exaggerated. It was found that cocaine-taking in the form of a powder used as snuff was extremely prevalent among this class, and that the outcome in many instances had been deplorable. Offences of a criminal nature had largely increased, the majority of the offenders being young negroes addicted to the cocaine habit and known as "coke" fiends.

In Virginia there are no restrictions regulating the sale of cocaine, and in consequence it can be more or less easily procured. A movement is said to be afoot to secure restrictive legislation in Virginia, in order to check the indiscriminate sale and use of this harmful drug.

There certainly should be measures enforced to regulate the sale of narcotics in the South, and negroes especially should be prevented from buying drugs of this kind. Their animal instincts are too strong and their brains too undeveloped to allow them the exercise of their own will in a question which concerns their physical and moral welfare, and to a lesser extent the public weal.

### Dust from the Demolition of Buildings.

This subject has already been discussed in the Medical Record, and the hope has been expressed that steps would be taken to stay what may be rightly termed the plague of dust in New York. The main factor in the creation of the present situation is the tearing down of old and insanitary premises, thereby disseminating dust and disease germs. Dust in itself is inimical to health, and as a conveyer of hurtful germs is a potent cause of disease. As the *Medical Press*, October 14, aptly remarks, "We must all eventually return to dust, but we do not want to do so too soon."

It is somewhat remarkable that legislation has not been evoked both in this country and in Great Britain, to mitigate a state of affairs which might, if not controlled, become almost unbearable. The London County Council has awakened to a sense of its duty to the public in this respect, and has set an example which other large American and British cities—especially New York—would do well to take to heart. The Council has decreed that the time for such work in London shall be restricted to the hours between six o'clock in the evening and ten o'clock in the morning. Further, it is made incumbent on those responsible for the work of demolition, to order that the walls be thoroughly watered during the process. It is said that Paris and some other continental towns have put into practice this simple method for some time past, and that the results have been eminently satisfactory, viewed from the standpoint of health and cleanliness.

### Requirements of Medical Practice in New Jersey.

The standard of medical education in New Jersey is high, and the value of a degree in medicine gained in that State is fully appreciated by its holders. This is as it should be, and it also appears just and right that the New Jersey State Board of Medical Examiners should refuse permission to physicians who have taken their degrees in other States, in which the standard is not so high, to practice in New Jersey until they have taken the State examination for medical license, and otherwise met the requirements of the State.

Dr. E. L. B. Godfrey, Secretary of the State Board of Medical Examiners of New Jersey, replying to a sharp criticism of the Board's methods which appeared in an editorial in the *Medical Bulletin* in November, denies that any objection can be taken to the policy pursued. The editorial in question declares the Board to have erected a Chinese wall of exclusiveness designed to shut out practitioners from other States from practising in New Jersey. Dr. Godfrey states that "no physician is debarred by the State of New Jersey from obtaining an indorsement of a certificate of license issued to him, after examination by another State, provided the standard of academic, medical and examining requirements of that State is substantially the same as that of New Jersey; and provided further that the candidate for license complies with the same conditions as are required from candidates examined by the State of New Jersey.

The academic requirements for a New Jersey State medical license are somewhat severe, but after all, when fulfilled, they merely testify that a man has received a liberal education, a more or less necessary adjunct to a physician's professional make up.

The medical requirements are four courses of lectures of at least seven months each, in four different calendar years, prior to graduation from a legally incorporated college.

There is but little doubt that the State Board of Medical Examiners of New Jersey is entirely within its rights when it refuses to recognize the principle of interstate medical reciprocity on unequal terms. To do so would furthermore be manifestly unjust to those physicians who have passed through the course laid down by the ruling powers in medicine of New Jersey. The only basis upon which a fair system of medical reciprocity between the different States can be established, is

by enforcing a uniform high standard of medical education throughout the country. The time is not yet ripe for this departure, and in the meantime, the medical profession in those States in which a high standard of medical education is maintained, must be protected against competition by practitioners from other States where it is less difficult to obtain a medical license.

THE STREET-CAR PROBLEM IN NEW YORK.

The difficulties in the way of successfully solving the problem of transportation in New York are probably greater than in any city of the world. There is no city anywhere in which the population is increasing at so rapid a rate as in New York, and there is also no city which, by its shape and the distribution of its inhabitants offers such obstacles to the evolution of a workable scheme of rapid and satisfactory means of transit. The population of New York in 1900 was 3,437,202 and, according to an article in the New York *Sun*, November 15, at the same rate of growth, in 1915 it will have reached 5,500,000. Official reports state that the number of passengers carried daily by the elevated roads during the year 1902 averaged 600,000, and the number carried by all the surface lines of the greater city averaged about two millions daily.

The present conditions of street transportation in New York are so bad that the only matter considered is how to improve the existing state of affairs, and no thought is given to the future.

The article in the *Sun* regards the question from the last named point of view, and discusses the predicament in which those who wish to travel in New York in 1915 may find themselves. The following table of the probable capacity of all the street transportation agencies that are at all likely to exist in 1915 is given.

Present carrying capacity of all local transportation lines in Greater New York, 1,167,124,000. Allow that the capacity of these lines may be increased one-third, equal to 389,040,000. Estimated capacity of subway system now under construction, 125,000,000. Proposed subway No. 2, 65,000,000. New surface, elevated, and subway lines in Brooklyn and Queens, 143,000,000. New surface and elevated lines in Manhattan, 50,000,000. New lines and extensions in the Bronx, 20,000,000. Total, 1,959,164,000.

It is estimated that the number of passengers to be provided for per annum in 1915 will reach the figures of 2,200,000,000, so that there will be more than 200,000,000 persons in New York who will be unable to ride, and to all intents and purposes the congestion will be proportionately as great in 1915 as it is to-day.

The *Sun* proposes that if the powers of the Board of Rapid Transit Commissioners are found to be inadequate to cope with the situation, a special commission should be created to take up the whole question of local transportation in New York, and to report such a project as will, in its opinion, meet the exigencies of a comparatively near future.

The conditions in New York at the present time, as regards street transportation, are serious to a degree. The facilities provided for carrying local passengers are ludicrously inadequate, giving rise to a state of affairs prejudicial to health and ofttimes to decency.

**Ovarian Tumors.**—The presence of a solid tumor floating in a considerable amount of ascitic fluid in a woman's abdomen is very suggestive of malignant or fibroid degeneration of an ovary. Ovarian fibroids are exceedingly scarce, and still more rarely is the disease bilateral.—*Washington Medical Annals.*

## News of the Week.

**Methodist Hospital, Philadelphia.**—It has been decided to erect a new dispensary building on the grounds of the Methodist Hospital. The structure will be 40 by 80 feet in size, of Pompeian brick, and it will cost $15,000.

**Contagious Diseases in Philadelphia.**—A total of 373 cases of disease classified as contagious—namely, notifiable diseases—was reported to the Philadelphia Bureau of Health for the week ended November 21. There were 118 cases of typhoid fever, with 11 deaths; 103 cases of diphtheria, with 13 deaths; 84 cases of scarlet fever, with 4 deaths; and 68 cases of smallpox, with 7 deaths. There were 407 deaths due to all causes, as compared with 374 for the preceding week, and with 448 for the corresponding week of the year before.

**Forcible Vaccination.**—Under the auspices of the Philadelphia Bureau of Health more than 400 negroes, members of the Church of God and Saints of Christ, assembled at prayer-meeting, were recently vaccinated by a corps of physicians, with the aid of a score of policemen. The members of this sect not alone have declined to be vaccinated, but they have also refused medical aid, and smallpox had spread among them, causing five deaths. A highpriestess of the church attended smallpox patients, treating them by means of prayer and the washing of feet. Two of these patients died and the coroner is to make an investigation.

**The Medical Club of Philadelphia** held a reception on November 20 in honor of Dr. S. Weir Mitchell. The guests included also Rear-Admiral Sigsbee, Surgeon Oliver P. Norton, U. S. N., Surgeon W. C. Kieffer, U. S. A., Dr. McGaney of the British Colonial Consular Service, Dr. Homer M. Thomas of Baltimore, Mayor John Weaver, and Judge Abram M. Beitber.

**Pennsylvania Hospital.**—The managers of the Pennsylvania Hospital have purchased adjacent properties to be converted into an additional annex for nurses and a building for ambulance purposes respectively.

**Smallpox in Philadelphia.**—For the week ending November 21, sixty-eight new cases of smallpox were reported to the Philadelphia Bureau of Health, just double the number of the week before. It has been necessary to close eight public schools for purposes of disinfection on account of the discovery of the disease in pupils or members of their families.

**Typhoid Fever Due to Milk.**—In connection with a small epidemic of typhoid fever in the southern part of the city, officials of the Philadelphia Bureau of Health discovered that a number of the patients had obtained their milk supply from a dealer who had himself suffered from a febrile disorder of obscure character. Examination of the milk disclosed evidences of contamination. Accordingly the supply was confiscated and destroyed, and the premises disinfected.

**The Taxation of Hospital Property.**—The Philadelphia City Solicitor has expressed the opinion that an ordinance exempting from taxation the property of the Garretson Hospital is not valid, because the power of exemption does not reside with councils by which the ordinance was passed. Only the Board of Revision of Taxes, the opinion holds, can decide as to properties that fall under the law of exemption from taxes.

**The Phipps Institute Lectures.**—The second of the course of lectures on the tuberculosis question, under the auspices of the Henry Phipps Institute

of Philadelphia, will be delivered by Dr. William Osler on Thursday evening, December 3, at 8.30 o'clock, in the auditorium of Witherspoon Building. The subject of the address will be "The Home in Relation to the Tuberculosis Problem."

**The D. W. Harrington Lectureship.**—The first course of lectures on this foundation at the University of Buffalo will be delivered by Dr. S. J. Meltzer of this city on November 30 and December 1, 2, and 3. The subject selected for discussion by the lecturer is "Œdema; a Consideration of the Physiological and Pathological Factors Concerned in Its Formation." The lectures will be delivered in the amphitheatre of the Medical College at 5 P.M. on the dates above given.

**Mount Sinai Hospital, Philadelphia.**—Estimates have been invited for the conversion of a former furniture factory into a hospital for the Mount Sinai Hospital Association. The structure is to be four stories high and be 38x75 feet in size.

**Diphtheria in Montclair.**—Dr. R. C. Newton, referring to a statement regarding a conflict between the Health Board and School Board in Montclair, N. J., writes that the friction was very slight and of short duration. The School Board declined at first to close one or two of the schools at the suggestion of the Health Board, but after a conference between the two Boards the schools were closed. There was a delay of only twenty-four hours. Twenty cases of diphtheria were reported during a period of nineteen days instead of ten, and now the outbreak is apparently at an end.

**Typhoid Fever at Williams and Brown.**—Outbreaks of typhoid fever which threaten epidemic proportions are reported from Williams College, Massachusetts, and Brown University at Providence. At Brown no cause for the outbreak is known, but at Williams the milk supply is suspected. All the students who are ill live in two of the fraternity houses. These secure their milk from the same source, and an investigation will be instituted at once.

**The Woman's Medical College of Pennsylvania** has planned the erection of a hospital as an addition to the college. In the past it has availed itself of the facilities of the Woman's Hospital, but objection having been raised by managers of the hospital to bedside instruction, the college finds it necessary to have a hospital of its own. For this purpose $75,000 are needed for a building and $425,000 for endowment.

**Dr. F. M. Oberlaender** of Dresden, in recognition of his labors in the study of genitourinary diseases, has, at the solicitation of his medical colleagues, been appointed professor by royal decree. Professor Oberlaender was the editor of the "Handbuch der Harn- und Sexual-Organe," to which many of the most eminent men in Germany contributed, and for which he wrote several chapters, notably those on chronic urethritis. He is editor of the *Centralblatt für die Krankheiten der Harn-* und *Sexual-Organe*. In this country Professor Oberlaender's reputation is due mainly to his advocacy of the treatment of chronic urethritis by the dilators which he devised; in doing so he gave credit for the fundamental idea thereof to the elder Otis. His large number of American followers will join in extending felicitations to the honor that, long merited, has at last come to him.

**A New Dispensary and Dormitory at Bellevue.**—The old building formerly used as the Bellevue Hospital Medical College has been converted into a dispensary for out-patients. The structure has been renovated and made fire-proof. The first floor will be used for the dispensary proper and the bookkeeping department, while the remaining three floors are to be used as sleeping apartments for the female employees of the hospital, who heretofore have been forced to sleep in the basement of the hospital buildings.

**Glanders at West Point.**—A strong effort has been made to stamp out an epidemic of glanders which has been raging in the artillery stables at West Point. Twenty-four horses afflicted with the disease have been shot and their bodies cremated. As a further measure of precaution the new artillery stable was burned. Several weeks ago ten polo ponies afflicted with the glanders were shot. Everything that has been near the affected horses has been burned and all precautions have been taken to prevent the spread of the disease among the hundreds of horses at the Military Academy. The men who had charge of the horses and who shot them, had to burn all their clothes and remain at the crematory, north of the Academy, until they were thoroughly fumigated.

**Christian Science Folly Sustained.**—The Ohio Supreme Court has placed its approval upon the right of believers in Christian Science to refuse to call a physician to treat a minor child. The decision came in the case of a man and his wife who were indicted in Butler County on a manslaughter charge for refusing to call a physician for their child, which died. They were acquitted, the State filed exceptions and these were overruled.

**An Interpretation of the State Nursing Law.**—In answer to an inquiry regarding the standing of the graduate nurses of the New York State Hospital training schools, Attorney-General Cunneen has given an opinion that the statute does not limit the right to practise nursing to registered nurses only. It does not require a regent's certificate or even a course of study in a training school for nurses as condition precedent to the right to practise nursing. It prescribes the conditions upon which one may obtain the right to the title of "registered nurse," but does not require unregistered nurses to discontinue their occupation. The statute merely prohibits persons who are not registered nurses from assuming the title or using any abbreviation, word, letter, or figure to indicate that they are so registered.

**An Administration Building for Willard Parker Hospital.**—Plans have been filed for a seven-story administration building to be erected at the foot of East Sixteenth street for the new Willard Parker Hospital. It is to have a series of offices on the lower floor and living quarters for the physicians and nurses of the hospital on the upper floors. The edifice will have an ornamental façade of brick with limestone trimmings and triple windows in the center with balconies. It is to be 66½ feet front and 48½ feet deep, with an extension 27 feet deep.

**An Antivivisectionist Brought to Book.**—An action for libel brought by Dr. William Bayliss, assistant professor of physiology in London University College, against Stephen Coleridge, secretary of the Antivivisection Society, resulted, a couple of weeks ago, in a verdict for £2,000 damages. Mr. Coleridge had publicly charged the plaintiff with torturing a dog while carrying out vivisection experiments without proper anæsthetics. Mr. Coleridge's charges rested on the statements of two Swedish women students, who had written a book. It was proved, however, that the animals experimented upon were completely under the influence of an anæsthetic. The gentle ladies, whose prevarications were repeated by Mr. Coleridge at such cost, wrote their book in the usual temperate style of the anti, as the following extract, culled by the *Sun* correspondent witnesses:

"The lecturer, attired in the blood-stained surplice of a priest of vivisection, has tucked up his sleeves and is now comfortably smoking his pipe, while with hands colored crimson," etc.

**More Consumption Cures.**—Dr. Marmorek of the Pasteur Institute of Paris recently presented a communication to the Academy of Science detailing the results of his experiments in the serum treatment of tuberculosis. His serum is prepared by the injection into horses of graduated doses of toxin extracted from cultures of tubercle bacilli, the result being an antitoxin of considerable strength. He stated that his results were most encouraging, though, owing to the insufficient number of experiments, somewhat inconclusive. He claimed to have obtained a positive cure in a number of cases in the early stages, and to have seen marked improvement in several advanced cases. His statements have been received with considerable scepticism in both France and Germany, and the Academy of Science refused to accept his manuscript, although it consented to the reading of the paper. Marmorek said he had resigned from the Pasteur Institute in order to devote himself to further and more extensive trials of the serum, but others say that the director, M. Roux, requested his resignation because he insisted upon the publication of his discovery on what Roux thought insufficient proof of its efficacy. Another and admittedly secret "cure" is announced in a long Associated Press despatch from Moscow. According to this report, remarkable cures of consumption have been effected in Russia by Kisel Zagoranski, formerly a mining engineer and now specially licensed by the Russian Medical Department to practise medicine in cases of tuberculosis. The proprietor of the alleged specific says he obtained the formula from the foreman of a gang of miners in Siberia. Prince Oldenburg of St. Petersburg, who maintains several hospitals in Russia and a big sanatorium in the Caucasus at his own expense, has offered to place at M. Zagoranski's disposal three beds in a St. Petersburg hospital, where he could accurately observe the results of the treatment.

**Gifts to the Richmond, Ind., Hospital.**—William B. Leeds of New York has given $10,000 to be added to the endowment fund of the new public hospital to be established in Richmond, Ind. Daniel G. Reid, also of New York, gave $30,000 several months ago. In addition to this the public subscribed $25,000, and the City Council has voted $10,000.

**A Medical Department for Brown University.**—It is reported in Providence, R. I., that Brown University will soon add the College of Physicians and Surgeons of Boston, Mass., to itself as a medical annex. John D. Rockefeller aided largely in the increase of the university's endowment fund, and it is hoped that he will become financial sponsor for the contemplated medical school, which, in any event, will remain in Boston. It was chartered by the Massachusetts Legislature in 1880.

**The Huntington Fund for Cancer Research** is now established in the Loomis Laboratory, 414 East 26th street, under the direction of Dr. B. H. Buxton and Mr. S. P. Beebe. The main object of the projected work is to approach the subject from the chemical rather than the pathological or bacteriological standpoint, and, generally speaking, to study the cell products of malignant growths in an attempt to determine if they are in any way different from those of normal tissues. For such work it is difficult to obtain sufficiently large amounts of material, and an appeal is made to surgeons and pathologists, whether in New York or elsewhere likely to have such material at their disposal to donate the same for the purpose of investigation. If such will communicate with Mr. S. P. Beebe, he will give instructions as to handling and forwarding.

**New Hospital in Orange, N. J.**—At a meeting of the Italian residents of Orange, held last Sunday afternoon, a movement was set on foot for the establishment of an Italian Hospital for Orange. It will be in charge of a Catholic Sisterhood, but will care for patients of any nationality or creed. The hospital will be established in a building to be rented within a week or two, so that patients may be treated at once. The plan is to erect a stone and brick building next year.

**Yellow Fever** is subsiding in Texas, a drop in the temperature throughout the State having put an end to the activity of the mosquitos. The quarantine against San Antonio was raised by proclamation of the Governor on November 18. Dr. Tabor of the Texas State Board of Health proposes that a delegation of the State Health Officers of Texas, Louisiana, Mississippi, and Alabama with representatives of the Public Health and Marine-Hospital Service, go to Mexico next January for the purpose of holding a conference with the Superior Board of Health of that country to determine upon a concerted plan of action that would prevent another epidemic of yellow fever in Mexico and the spread of the disease to Texas and the South next season.

**Medical Jurisprudence Society of Philadelphia.**—At a meeting, held November 16, Dr. Solomon Solis Cohen read a paper entitled "Judicial Determination of the Cause of Death." He criticised the current system of expert evidence in trials for murder, and suggested the establishment of a new system, the chief feature of which should be a jury of physicians, surgeons, chemists, or bacteriologists to determine the cause of death prior to trial before a petit jury.

**Opposition to the Plan of Organization of the American Medical Association.**—At a meeting of the Dubuque Medical Society, held November 11, 1903, a resolution was unanimously adopted disapproving of the plan of reorganization embodied in the constitution and by-laws adopted at the recent meeting of the State Medical Society, and an appeal to the profession of Iowa to oppose such reorganization has been issued. The chief of the objections offered against the project are the following: "(1) Compulsory membership in the State Society and all its un-American, unrepublican outgrowths; refusing membership in a local society to such as do not wish to be members of the State Society. (2) The whole scheme of organization from above down instead of from below up, which thus reverses the normal law of growth or organized social and political bodies and is particularly obnoxious to an American citizen. (3) The 'censor of his district' with judicial functions, an intolerable and offensive naturalization of the walking delegate in the field of our home societies. (4) Abrogation of home rule, which in part might be conceded for the sake of the advantages of a properly constituted federation, but which advantages are conspicuously absent in the proposed scheme or secured at too great expense. (5) The establishment of the council, a body of ten members with a five years' tenure of office, amenable to no person or body, to whom are delegated extraordinary powers, from whose judicial decisions there is no appeal; who, in addition, are *ex-officio* members of the House of Delegates, of which they will form a large proportion, estimated at from 20 to 30 per cent. Such centralization of power is not wise. (6) The entirely inefficient provision for a referendum, viz., that upon questions pending before the House of

Delegates, the general meeting of the society may order a general referendum which the House of Delegates *may* (or may not at their pleasure) submit to the general membership! A shadow of referendum without its substance." The county societies which have not yet recognized are urged to delay such action until they have carefully and critically examined both the State and the County constitutions and by-laws under which they are asked to organize, and such as have already taken this step are asked to reconsider their action.

**Pathological Society of Philadelphia.**—At a stated meeting, held November 19, Dr. John M. Swan exhibited an aneurysm of the arch of the thoracic aorta. The specimen was obtained from a man, seventy-seven years old, who presented an inguinal hernia and complained only of abdominal pain. Death occurred suddenly, and it was thought from cerebral hemorrhage. On post-mortem examination the several serous cavities were found filled with fluid, and the kidneys were in a state of chronic degenerative inflammation. The heart was greatly enlarged, its cavities dilated, and its walls thickened. The valves were normal. The aorta, however, exhibited a fusiform dilatation of its arch, and the entire artery was uniformly dilated throughout its thoracic and abdominal portions, as well as the seat of most extensive atheroma. The brain was not examined. Drs. Thomas G. Ashton and H. R. M. Landis exhibited an aneurysm of the aorta, associated with gastric ulcer. The patient was a colored man, who exhibited at first signs of pleural adhesion and thickening on the left side, later complicated by bronchial breathing and the development of a bruit and inequality of the pupils. The patient expelled blood from the mouth, but whether from the lungs or the stomach could not be determined. Death resulting, the arch and the thoracic aorta were found the seat of two aneurysmal dilatations, one of which had apparently eroded the œsophagus. Dr. Samuel McC. Hamill presented a specimen of aneurysm of the arch of the aorta, with rupture. The patient had been a woman, fifty-five years old, who had been under observation and had been known to have had her aneurysm for fifteen years. Death resulted from rupture into the pericardium. On post-mortem examination the arch of the aorta was found to be the seat of a fusiform aneurysm of considerable size, partially filled with laminated clot. Dr. George B. Wood presented a communication entitled "Tuberculosis of the Parotid Gland," reporting the case of a man from whom a portion of the enlarged parotid had been removed, together with an adjacent gland, and in both of which the histological alterations of tuberculosis were found, though the presence of tubercle bacilli could not be demonstrated. He pointed out the importance of the tonsils as a portal of entry for infection with tubercle bacilli as well as with other microorganisms, and he cited personal observations and those of others tending to confirm this view. Dr. Robert N. Willson presented microscopic preparations suggestive of the presence of malarial parasites, diplococci and influenza bacilli in the blood. The patient, a woman, presented almost typical appearances of pernicious anæmia, while the hæmoglobin-percentage was about 20 per cent., the number of erythrocytes between one and two millions; the leucocytes were only slightly increased, with a preponderance of mononuclear forms. Apparent malarial plasmodia were found in the stained, but not in the fresh blood, together with diplococci, although on culture only influenza-bacilli were obtained. Drs. Courtland Y. White and Isaac Leopold presented a speciman of aneurysm of the arch of the aorta, from a man about forty-five years old, with a history of syphillis, and who was afforded considerable amelioration by means of subcutaneous injections of gelatin. Hoarseness, with paralysis of one vocal band from involvement of the recurrent laryngeal nerve, was one of the first symptoms, and at a later stage, dysphagia was a source of discomfort. Death resulted from exhaustion, and on post-mortem examination the arch of the aorta was found the seat of a large aneurysm partially filled with laminated clot, and on which was seated a secondary dilatation. Dr. Lambert Ott presented a specimen of a mammary gland removed on account of the presence of a neoplasm. Dr. Robert N. Willson presented a microscopical specimen of diplococci obtained from the urethral discharge from a young man, who, in the sequence of an attack of gonorrhœa, the discharge from which contained typical gonococci, developed tonsillitis, and diplococci being subsequently found in the urethral discharge.

**Obituary Notes.**—Dr. Robert D. Murray, Surgeon of the Public Health and Marine-Hospital Service, regularly stationed at Key West, but recently on yellow fever duty at Laredo, Tex., died November 22 from injuries sustained in a runaway accident one week ago while returning from the bedside of a yellow-fever patient whom he had been treating. When he had been in the hospital several days pneumonia set in, resulting in his death. Dr. G. M. Guitéras, who was with him at the time of the accident, was thrown from the carriage, but suffered only some severe bruises. Dr. Murray was a native of Ohio, sixty-four years old, a Civil War veteran, and a member of the Grand Army of the Republic. He was graduated in 1868 from the Cleveland (Ohio) University of Medicine and Surgery, and for a time held the chair of anatomy there. He then studied at the Jefferson Medical College, taking his degree there in 1871, and the following year he entered the Marine Hospital Service. During his connection with the service he had been in charge at Norfolk, Va.; Mobile, Ala.; Philadelphia, New Orleans, and Key West, Fla.

Dr. Allen Hazen of this city died on November 17, at Jerico Centre, Vt., after an operation for appendicitis. He was graduated from the College of Physicians and Surgeons of this city in 1895, and was a member of the Society of Alumni of the City Hospital, where he served as resident physician for two years. He had been on the Board of Medical Examiners of the Mutual Life Insurance Company of New York for about five years.

Dr. Charles A. H. De Szigethy died on November 17 at his home in Brooklyn, in his sixty-sixth year. He was a Hungarian, born in Transylvania, and in early manhood was prominent among the Hungarian patriots in their fight for freedom. He studied medicine at Giessen, and on coming to America, in 1865, settled in Brooklyn, where he practised medicine till 1883, when ill health compelled him to go to California. Recovering his health, he resumed practice in Los Angeles, which he continued till 1894, when he returned to Brooklyn.

Dr. Samuel Talmadge died at his home in Brooklyn on November 20, at the age of seventy-two years. He was born near Somerville, N. J., and was graduated in medicine from the New York University in 1870.

Dr. Herbert A. Starkey of Rondout, N. Y., formerly surgeon of the Pullman Company at Pullman, Ill., died suddenly on November 21. He was born thirty-five years ago in Philadelphia and was graduated from the Medico-Chirurgical College in that city in 1889.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

THE KING AND HIS SANATORIUM—NON-HYATID CYSTS OF THE LIVER—HOSPITAL SCHEMES FOR EXTENSION; BART'S, KING'S, ST. THOMAS'S—POLYTECHNICS *vs.* UNIVERSITIES—QUALIFIED NURSES— MISS HICKMAN—HOSPITAL SHOPPING DAY—OBITUARY.

LONDON, November 6. 1903.

TUESDAY was a red letter day in the annals of medical charities. On that day King Edward laid the foundation stone of his sanatorium, for the open-air treatment of consumption. The site selected for this great institution is in one of the most beautiful districts of the country, about three and one-half miles from Midhurst (Sussex), and seven from Haslemere (Surrey). The landscape is of an undulating character and clad with pines, Scotch firs, and oaks. Spanish chestnuts and holly, rich just now with red berries, are scattered among the bracken and heath. One present at the ceremony says the odor of the pines was quite heavy in the air. A large number of distinguished persons had been invited, and were present to receive the King, who arrived with royal punctuality. The company, naturally, included his Majesty's advisory committee, besides a goodly number of other eminent representatives of the profession. Locally, everyone turned out from a considerable distance. The "oldest inhabitant" was there, and all gradations of age down to the school children, who assembled to sing the national anthem.

The sanatorium will stand in a park of one hundred and fifty-one acres, at an altitude of 495 feet, sheltered to the north and east by ground gradually rising to a height of 630 feet, crowned with pine trees, which also give some shelter to the west and southwest. The south is open to the sun. There will be gardens with graded walks and the best forms of shelters. Southward the view embraces the noted South Downs. The climate is equable and mild; annual rainfall, 30 inches; mean temperature, 48° F.; mean maximum, 57.1; mean minimum, 41.4. The primary object of the sanatorium is to provide for sufferers of a class above the very poor, but as it is to provide the very best accommodation, the King did not think those who could afford to pay for it should be entirely excluded, and, therefore, at his Majesty's suggestion, twelve beds will be set apart for them. The administration building will be separate, connected with that for patients by a central corridor on the ground floor only

On the 'King s arrival an address was read on behalf of the advisory committee, which recapitulated their proceedings and described the results. The King replied in a speech referring to the most important points in the address, and thanking those who had enabled him to bring his plans so far toward completion. His Majesty said, "When a generous donor, whom I regret I am not allowed publicly to thank, placed at my disposal a large sum of money for any philanthropic object which I might have in view, I at once decided to devote it to the erection of an open-air sanatorium, having been so greatly impressed with the immense benefit which institutions of this nature conferred on those suffering from pulmonary diseases." His Majesty went on to express his hope that in not a few cases treated in the institution the malady would be arrested, and further his trust that "on their return home, by diffusing among their relatives and friends a knowledge of the infinite importance of fresh air and sunshine in maintaining health, the conditions under which in so many homes tuberculosis flourishes will be sensibly diminished." Having taken up other points, the King said that while no necessary comforts would be omitted for the welfare of the patients, "there will be a total absence of all luxury and of expenditure of money on superfluous appointments." He then expressed regret that the Queen was unable to be present, as she was deeply interested, like himself, and in conclusion added, "We both of us pray that the institution of which I am about to lay the foundation stone may receive the blessing of God, and that those who come to reside here may find renewed health and strength to enable them to carry on their duties in the world."

A short religious service was then conducted by the bishop of the diocese, the King in its course laying the stone with the usual ceremony, after which a hymn was sung and the bishop pronounced the benediction. The King lingered some time on the platform, admiring the lovely landscape on which the sun shone with a radiance so rare in this rainy year, that it seemed to many an augury of good. He expressed to his committee satisfaction and delight with the natural charms of the site selected, and as he returned to his carriage the assembled multitude sang the national anthem.

The Royal Medico-Chirurgical Society has commenced to work. On the 27th ult. the new regulations as to the admission of officers of the public services having come into operation, several of these gentlemen were elected service fellows.

Mr. Clement Lucas showed a case of primary chancre beneath the tongue in a man of thirty-five years, who said he could not account for the sore, except that in his shop the men smoked any pipe lying about.

Mr. Alban Doran contributed a paper on simple non-hydated cysts of the liver, founded on a case in a woman of forty-two years who fell against a washing tub in the second month of gestation, about three years previously. The accident produced abortion, but she became pregnant again and went to full term. Jaundice appeared four months before admission, when the liver was greatly enlarged by, as was thought, a cyst. This was found to be so on operation. The cyst was opened and three pints of green bile drawn off. No calculi or hydatids present. The gall-bladder and ducts were found to be quite unconnected with the cyst, empty and not obstructed. A ½-inch drainage tube was placed in the cavity, and for three weeks bile flowed freely and the jaundice decreased. In the fifth week the motions began to be colored. The patient left the hospital on the thirty-eighth day. The drainage tube had been removed on the seventeenth day, and the discharge through the fistulous tract gradually diminished. The cyst was occasionally washed out with chinosol, and Condy's fluid was used at home when last seen, October 19. She seemed in good health, but a little pus was still discharged from the fistula. In commenting on the case, the operator remarked on the complete absence of shock, which he attributed to the fact that the free incision enabling him to see all the parts involved rendered it unnecessary to handle them much. When the incisions were accustomed to be made short and the fingers had, so to say, to work in the dark, the operator must have bruised important structures, more or less, and in those days alarming shock was frequently met with.

Mr. Bruce Clarke thought the cyst was probably due to the injury, though it might have depended on a retention cyst or have been congenital. He mentioned a case of an epileptic who fell on some hard substance in one of the fits, had great collapse, and six weeks later, operated on for hydronephrosis, a renal vein was found to have been ruptured into the cyst. The jaundice, he thought, was produced by pressure. The diagnosis from malignant disease rested on the duration of the case.

Mr. Willett, president, suggested, as an explanation of the delay in the bile passing into the bowels after the operation, that probably there was an opening of the duct into the cyst which offered a freer passage until the contraction of the cyst forced it into the natural channel.

The St. Bartholomew's Hospital extension scheme, as recommended by the Mansion House Committee, has now received the decided sanction of the governors. Yesterday a "General Court of Governors" was held, at which about seventy were present, and a series of resolutions (proposed by Mr. C. A. Cripps, K.C., and seconded by Sir Wm. S. Church, Pr. R.C.P.) were carried with only one dissentient. These resolutions recorded unqualified satisfaction that after impartial exhaustive inquiry the Mansion House Committee had arrived at its conclusions, and thanking them for the large amount of time and attention bestowed on all matters connected with the inquiry.

I informed you at the time of the nature and extent of the committee's scheme, but now that it is completely endorsed by the governors I may repeat that provision is to be made for (*a*) additional operating theaters; (*b*) new casualty and out-patient departments; (*c*) new nurses' home; (*d*) new quarters for resident medical and surgical staff; (*e*) isolation block and other new ward blocks to replace those to be demolished; (*f*) new mortuary, post-mortem rooms, and pathological department; (*g*) internal structural rearrangement of the east, west, and south wings. You will see that the alterations will be very extensive, and will not be surprised if some old students are saying to each other "why, we shall hardly know old Bart's when it is finished." But the change will be gradual. The first block to be built is to be the new casualty and out-patient departments with dispensary, etc. The operating theaters will proceed simultaneously. Then the nurses' home. The other blocks will be undertaken in such order as their relative urgency may make expedient, having regard to the general work of the hospital.

One of the most important resolutions directs that the medical staff be consulted from time to time on all details that affect the sanitary arrangements, the care of the patients, or the interests of the medical school. The staff is also to be consulted as to the plans submitted by the architects for carrying out the resolutions, and as to any modifications that may from time to time seem desirable. Application will be made to Parliament in the ensuing

session for such powers as may be necessary to complete the improvements, including the utilization of the church within the hospital precincts and the union of the parish of St. Bartholomew's the less with the adjacent St. Bartholomew's the greater.

The Treasurer and Almoners will shortly wait on the new Lord Mayor to ask him on behalf of the Court of Governors to convene a meeting of the citizens for the purpose of raising the necessary funds.

A suitable site of twelve acres in South London has been presented by a single donor to which to remove King's College Hospital. An appeal for funds to build and equip the new hospital is being made. Not less than £300,000 is required. The transfer of the charity from a district which has been considerably denuded of its poorer inhabitants to one in which there is a dense population inadequately supplied with hospital accommodation will probably so far commend itself to the public as to render the appeal successful.

It is proposed to increase the accommodation at St. Thomas's hospital for paying patients, and application has been made to the Charity Commissioners to sanction such an extension. Two floors in a building, to be erected in the hospital precincts, are to be devoted to this purpose, the remainder being used for a nurses' home. The scheme includes a provision that the governors may let portions of their land in allotments, subject to the provisions of the Allotment Acts.

The Marquis of Londonderry, speaking at the Northern Polytechnic last week, said he should never regret the two years he spent as chairman of the London School Board, which gave him an insight into the management of education. The present polytechnics and universities were doing excellent work, and with prudence, economy, and energy their full usefulness could be attained. Before investing money in any scheme we should be assured of a good return. Sir N. Lockyer had asked for twenty-four millions for university schemes, but what would be the return for such vast expenditure. It was not true that large numbers of well-prepared students could not enter the existing universities.

Mr. Bryant, late P.R.C.S., presided at a meeting of the Hospitals' Association at St. Thomas's Hospital for discussing the proposal to form a new grade of nurse for poor-law service to be called a "qualified nurse." Dr. T. D. Savill, formerly superintendent of the Paddington Infirmary, and Miss Gibson of the Birmingham Infirmary, spoke against this proposal and showed the many objections to it. A resolution in opposition to the scheme was carried, and it was determined to ask the President of the Local Government Board to receive a deputation on the subject.

The inquest on Miss Hickman has been again adjourned, but it seems clear that the case is one of suicide, as Dr. Stevenson has detected morphine in the organs and in the hypodermic syringe found near the body.

Hospital shopping day was duly carried out on Tuesday, and some checks as the result have already reached the King's Fund; so notwithstanding the objections which have, naturally, been offered in some quarters the day may become a recognized institution.

The deaths are announced of Dr. Fray Ormrod, senior surgeon of the Workington Infirmary and one of its founders, on the 1st inst., aged sixty-five. Dr. R. F. B. Halpin, Physician to the Arklow Fever Hospital, etc., on the 19th ult., from pneumonia in consequence of getting wet on a night visit. He was only forty-five years old. Dr. Thornburn of Cockermouth, aged sixty-four years, on the 30th ult. Dr. H. A. Lawton of Poole, on the 31st ult., aged fifty-two years.

## OUR PARIS LETTER.

(From Our Special Correspondent.)

PRIMARY DIPTHERITIC TRACHEOBRONCHITIS—THREE CASES OF SLEEPING SICKNESS PRESENTED TO THE ACADEMY OF MEDICINE—TWO NEW CASES OF DERCUM'S DISEASE—STUDENTS' ANTI-ALCOHOLIC LEAGUE—CRUSADE AGAINST DICHOTOMY.

PARIS, November 6, 1903.

PRIMARY diphtheritic tracheobronchitis is a disease which has been rarely seen, and is not admitted without reserve by classical authors. Drs. Sergent and Lemaire have recently reported a case to the Hospitals Medical Society. The patient was a young woman twenty-one years old, who, on entering the hospital, was found to be suffering from intense dyspnœa. There was no angina, no coryza, no adenopathy. On laryngoscopic examination being performed, no croup was found, but the signs of a double recurrential paralysis. Tracheotomy was performed and false membranes were thrown out. After this, there was some relief. A bacteriological examination showed the diphtheritic nature of the membranes, and 70 cubic centimeters of serum were injected in four days.. The third day she threw up a bronchial cast 15 centimeters long. Death took place, however, on the sixth day from uræmia. The autopsy showed two peritracheal bronchi, and it was found that even the alveoli were infected by the Loeffler bacillus. The disease had begun eight days before the patient came to the hospital, and there had been no angina, and only symptoms of bronchitis. Dr. Legendre reported a similar case.

At a recent meeting of the Academy of Medicine, Dr. Blanchard presented three negroes suffering from sleeping sickness, who had been brought back from Africa by Dr. Brumpt, his assistant. In two of these cases there is swelling of the glands of the neck. Brumpt has tried to inoculate the disease to rats, mice, guinea-pigs, but without result. A monkey, however, was infected, but no histological examination was made. Dr. Chantemesse remarked that Castellani and Bruce had been able to inoculate the disease to rats and dogs. It is possible, according to Brumpt, that a species of fly, called glossina palpanis, is the means of contagion. The latter is found in the regions affected by this disease.

Drs. Sicard and Roussy have recently reported two cases of Dercum's disease in women who had been subjected to ovariotomy. The four cardinal symptoms were seen in these two cases: localized adiposio, asthenia, motor troubles, and pain.

The students of the Latin quarter, or at least, a certain number of them, are getting up an anti-alcoholic league, which will form part of the French league of temperance. The members only abstain from distilled liquors, but drink all fermented beverages, such as wine, beer, or cider. The fees for admission and membership are one franc for each member, and the league intends to use every possible means of impressing on the public the importance of temperance, such as post-cards, advertisements, tracts, hospital propaganda, temperance restaurants, and later, the establishment of a journal.

The question of what physicians should be paid, when one of their patients is operated, and that of what is called "dichotomy" in France, a percentage which the physician receives from the surgeon whom he calls in, has been discussed in France quite extensively during the last few months. To give an example of what would take place. A physician would decide that a patient needed to have an operation, such as curettage performed. A surgeon would be called in and would charge 5,000 francs and give his confrère 1,000 francs. Such proceedings could not be tolerated, and various scientific bodies have sought to regulate and define what should be done in such cases.

The Medical Syndicate of Versailles, which enjoys a very high reputation, unanimously adopted, at a meeting held last October, the following resolutions: (1) A surgeon or specialist, who has decided to perform an operation, should notify the patient's physician and ask him to assist. (2) It concerns the physician to determine as well as his own fee, those of the physician and of his aids, and to indicate this to the family. These fees include the operation itself, and the physician should present his bill for the other services rendered. (3) When the surgeon lives in another city, he is not required to notify his confrère, but it is more courteous to do so, and ask him, either as a friend or as an aid, to assist at the operation. The family may also ask this. In the first case the surgeon should pay the fee of the physician, in the second, the family is called upon to do so. These regulations are designed to put a stop to the system of commission which is getting to be known by the general public, and is a disgrace to the medical profession.

## IS HEART DISEASE THE CAUSE, OR THE EFFECT OF THE ATHLETIC HABIT?

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: The item on page 702, MEDICAL RECORD, "He (Lewin) was seized with an attack of cardiac syncope just before the close of the first half (foot-ball contest), and died shortly after being carried from the field," reminds me again of the commonly recognized fact among physicians that the abuse of athletics is liable to lead to heart disease. For some time, however, there has been a query in my mind whether exaggerated heart action is not a chief cause of the love of athletics, the latter becoming indirectly the cause of hypertrophy and dilatation as a result of said *penchant*. Children and young people who are addicted to great physical activity usually show signs of strong heart action, and when, on examining applicants for insurance, I have found that kind of cardiac innervation which enables persons consciously or unconsciously to induce the heart to beat strongly and rapidly they have admitted a disposition to overdo and put forth such effort as successful competition in athletics or labor calls for.

On the other hand, I do not recall an instance of de-

pressed cardiac innervation which seems normal to some people, to have been accompanied by love for athletic sports. Such persons may work more or less hard for gain, but not for sport.

It has seemed to me that the positive condition is often one of exalted innervation, but after this has led for years to over-exertion there may be added hypertrophy, dilatation, and murmurs.

The practical lessons are: (1) The family physician should examine the well, and not alone the sick, of families under his care, that he may caution those who have nervous heart to steady the organ as they can learn to do with experience, and be as much on guard against over-taxing it when they feel in best condition as when "under the weather."

(2) Finding an abnormal heart with no history of rheumatism, etc., to account for it, one should remember a possible cause in exalted heart action from youth up, with resulting physical strain.

(3) The bearing which such a heart has on the probabilities of life, on insurance. In young people we might expect the heart with exaggerated innervation or activity to withstand acute disease better than one with depressed innervation, but it would be more likely to tempt disease. Long life, however, seems to favor the harmonious man, who by nature is moderate in all things."

R. C. SHULTZ, M.D.

LOS ANGELES, CAL.

# Progress of Medical Science.

*The Boston Medical and Surgical Journal, Nov. 19, 1903.*

**Observations on the Effect of Catheter Drainage on the Function of the Kidneys in Interstitial Nephritis and Pyelonephritis.**—Arthur Tracy Cabot presents the following conclusions: (1) The relief of tension in kidneys that, owing to long obstruction, are exhibiting the clinical phenomena of interstitial nephritis usually brings about a return of normal function. From this, it would appear that the renal condition is directly due to the obstruction and increased tension. (2) It seems probable that in cases of dilated ureters, permitting regurgitation of urine from the bladder back into the pelvis of the kidneys, a long drainage of the bladder will permit such a shrinkage of the ureters and ureteral orifices as to restore the normal vulvular action of the ureters and the retroflow of the urine will thus be stopped.

**A Case of Epilepsy and Nephritis Simulating Puerperal Eclampsia.**—Philip H. Cook makes this report. The patient was a woman aged thirty-four years; she was about nine months pregnant. Her friends stated that she was of a nervous disposition and subject to epileptic seizures, the last of which had occurred about one month before. She had felt well throughout pregnancy, aside from the one convulsion. Her eyes had not troubled her. Three preceding labors were normal. Examination showed marked œdema of the legs and feet. The nitric acid test showed that the catheterized specimen was laden with albumin. Labor progressed normally, and the child was born at 12.43 A.M. At 9.50 A.M. the patient complained that the light hurt her eyes. Twenty minutes later a convulsion occurred, and lasted about two minutes. Milk diet and diuresis were ordered as well as a hot pack. Examination revealed many casts in the urine, besides squamous and large round epithelial cells. There was a rare normal corpuscle, leucocyte, and small round cell. Her husband stated that she had been subject to attacks for fifteen years. In ten days after the convulsion there was only a slight trace of albumin in the urine. No casts were seen. There was some pus and blood. The œdema had nearly disappeared. An increase in diet was followed by another convulsion. Full consciousness returned in about twenty minutes. From this time on convalescence was uneventful, and three days later the patient was discharged well.

*Journal of the American Medical Association, Nov. 21, 1903.*

**The Cultivation of Trypanosoma Brucei.**—This is the cause of nagana or the tsetse fly disease of South Africa. The organism seemed at first to be a parasite, and as such incapable of existing outside the living body, but the authors, F. G. Novy and W. J. McNeal, have successfully cultivated it and followed out the usual inoculation experiments, white mice, rats, and guinea pigs being the animals employed. The culture medium employed was the ordinary nutrient agar containing variable amounts of defibrinated rabbit blood. A first series of twenty-five experiments failed. In a second series of the same number, four positive cultures were obtained from as many animals. One culture has been carried to the seventh generation. No definite statement can yet be made as to the possibility of immunizing animals. The greater portion of the paper is occupied with experimental details and differential data as to the various species of the trypanosoma.

**The Protoplasmic Activity of the Renal Epithelium.**—This subject has been studied by W. S. Carter, who has noted the elimination of pigments injected into the circulation. He alludes to the filtration-absorption and excretory theories as to the mode of secretion of the urine and then describes his own experiments. These lead him to believe that the excretion or the Bowman-Heidenhain theory is the correct one. He claims for his experiments, however, merely that the pigments are excreted by a protoplasmic activity of the renal epithelium. It may well be that some of the pigment is filtered through the glomeruli. This latter seems to more definitely result from the use of certain pigments than from others. Finally the author notes that the elimination of pigments by the kidney does not afford a method of determining positively and finally whether the rodded epithelium of the organ is excretive or absorptive in function, though as above indicated he inclines to the former view. Of course, urea and the metabolites of the urine may be handled in a different way from foreign substances injected into the circulation. However, it seems improbable that the cells lining the uriniferous tubules are concerned exclusively in absorption.

**The Surgical Treatment of Traumatic Hemorrhage of the Spleen.**—N. Senn reviews the history of splenic injuries and of the various methods employed for the relief of hemorrhage from this organ. He then relates the series of experiments performed by himself on dogs to ascertain the effects of forcipressure of the wound margins. In this method, under slow broad pressure with forcipressure forceps, the pulp of the spleen is displaced from the meshwork of loose connective tissue which, in turn, is condensed into a broad firm band in which the larger blood vessels become entangled, their cut ends contused, and hemorrhage even of branches of the splenic artery of considerable size and large veins is arrested. Senn found that this method was of great value. All of the wounds experimentally made in the dogs were clean cut incised wounds, calculated to bleed profusely, and in all the bleeding was arrested by the crushing and suturing of the crushed margins. Secondary hemorrhage never occurred. The post-mortem specimens invariably showed adhesions between the omentum and the wound surfaces. In two instances small localized abscesses developed, probably from infected ligatures. Other methods of treatment alluded to are splenectomy, partial or complete, splenorrhaphy, aseptic tamponade, and cauterization. He believes the forcipressure and suture method the best of all. Catgut is the suture material advocated.

**Destructive Sterilization by Cataphoresis of Cancer of the Uterine Cervix.**—G. Belton Massey regards cauterization by the galvanocaustic knife as lessening the chances of reimplantation of the growth in the cut edges incident to operation by the knife. The author describes in full detail the electro-chemical method employed by him for some years. By this method no preliminary opening of the lymph and blood channels, with possible instantaneous admission of cancer cells, is required, the growth being destroyed and sterilized *in situ*, and the sterilization then carried to any desired depth and in any desired direction by small, easily handled instruments, with complete protection of the external parts from accidentally straying force, and without appreciable heat production. A powerful electric current is employed in this method for the development, within the substance of the growth, of nascent oxychlorids of mercury and zinc, from a union of electrolytically freed oxygen and chlorin with the mercury and zinc of an amalgamated electrode. These nascent salts thus produced during application are radiated in all directions by the continued flow of the current, devitalizing the protoplasm of the neighboring cells, particularly the better conducting lowly vitalized malignant cells, and the outflow may be governed and directed by the operator until both the center and the periphery of the growth are devitalized and sterilized, the destroyed tissues assuming a whitish-gray aspect. The time required for the total destruction of an average cancer of the cervix varies from a half hour to two hours, with a current of 500 to 600 milliamperes, the patient being under a general anæsthetic, as for a major operation. The slough produced comes away in from ten to twenty-one days. The author has to report only four cases, however, treated exactly in the way he describes, and in only one has there been an absolute success, the patient being alive and well six years after operation. All the rest were recurrences after knife operations, and, with the exception of one case that proved fatal from peritonitis within six days, they were all greatly benefited for a time, usually dying ultimately from a metastasis

that, according to the author, must have been implanted before the application.

*Medical News, November* 21, 1903.

**The Relation of Mild Types of Diphtheria to the Public Health.**—Thomas W. Salmon quotes from Parsons of Roche, England, that outbreaks of diphtheria are often accompanied by a similar prevalence of sore throats not distinctly diphtheritic in character. It is probable that though such cases may not, from a clinical point of view, come within the definition of diphtheria they are essentially of the same nature, and a susceptible person coming in contact with one of them may contract the disease from it in a severe form. The existence of these cases should receive official recognition, and they should be assigned a definite place among the varieties of diphtheria. The same sanitary regulations should be used in these mild types of the disease.

**"The Heart Cure," Its Terminology, Purposes, and Achievements, Including the Etiology of Fatty Degeneration.**—Homer Wakefield says that by the aid of temporary prolongation of the heart's stimulation, he endeavors to restore the systemic oxidation, to lighten the load as much as possible of the heart's hard task and to rid the system of the autointoxication which incidental putrefactions have caused. The former part of the treatment is accomplished by the free inhalation of an abundance of nascent and purified oxygen gas, made fresh several times daily. The second factor consists in the clearing of the vascular system. The portal system is cleared by oft-repeated, very small doses of calomel and a saline cathartic. Warmth is applied to the extremities, while cold water is taken internally. The two principal degenerations of heart disease, gelatiniform and fatty metamorphosis, are wholly due to and dependent upon the suboxidation which results from cardiac and blood deficiencies and their vicious cycle., and are preventable, arrestable, and restorable in the great majority of cases. Many persons live years after being treated by the heart cure.

*New York Medical Journal, November* 21, 1903.

**Clinical Study of the Use of Antitoxin in Hay-fever During the Season of 1903.**—The antitoxin referred to is the one devised by Dunbar and exploited by the latter, Semon, McBride, Mayer, and others. A. W. MacCoy has employed the remedy in fifteen cases, six of which are reported in detail. His cases were typical ones, presenting the classical picture of the disease. The serum was applied to the conjunctival and nasal mucosa by means of a pipette, one or two drops from two to four times daily for the eyes and double the quantity from two to six times daily for the nose. Results in all the fifteen cases were most satisfactory, the attacks being generally promptly aborted. MacCoy believes that it remains to be determined whether there are in America some cases of hay-fever not amenable to cure by the use of the antitoxin serum of Dunbar. So far as my fifteen cases can illustrate, they appear to confirm the contention of Dunbar, that cases of hay-fever are dependent upon the toxin resident in the various pollens of *grasses*.

**Brain-fag and Its Effects on Health.**—J. Knott describes the general arrangement of those portions of the brain presiding over the mental faculties, and notes the tremendous strain placed on them in modern civilization. He notes that the brain, like all other organs of the body, receives during health a supply of blood fairly proportional to its activity at a given moment. The blood vessels here, as elsewhere, are provided with muscular and elastic coats, and their caliber is accordingly under the control of the nervous system. When the nerve centers are exhausted this vasomotor control is lost to a certain extent. Moreover the cerebral vessels are thin-walled and yielding beyond those of other organs. When this process of overstrain has been too prolonged, the coats of the blood vessels of the part partially lose their elasticity and are slow to recover their ordinary healthy contractility. When the stage of exertion has been too much or too often repeated, the walls of the vessels tend to lose their contractility and remain constantly dilated, thus giving rise to chronic congestion. Then follow changes in the mental faculties. The individual loses his decisive resource, resolve, and capability of continuous action. Furthermore, the well-known physiological fact that mental work tends to check the secretion of the gastric juice, tells rapidly on the digestive functions of those anxious and worried individuals who cannot, or will not, allow themselves a fair amount of rest after meals. This habit, when continued, tends, with the restlessness and sleeplessness which torture the unhappy owner of an overworked brain, to reduce him to the state of a morose dyspeptic, whose life is a burden to himself, and whose presence is unpleasant to others; and who has little to look forward to in life but the dreary accompaniments of a premature old age. Such are the evils which, with the innumerable smaller collateral ones, are brought on by the refusal to the organ of thought of its due share of rest.

*American Medicine, November* 21, 1903.

**Prevention of Tuberculosis.**—J. W. Wherry cites two cases in which the patients developed tuberculosis. They had both attended the same telephone in an institution for tuberculosis. The officers and clerks used the same instrument often. Whether the infection was carried by means of the telephone cannot be absolutely known, but the writer states that it is very probable.

**The Treatment of Surgical Shock by Adrenalin.**—Edward Martin and M. E. Pennington report cases in which the effect of adrenalin seemed to be life saving. Laboratory experiments apparently show that adrenalin by intravenous injection is the most powerful, practicable cardiac and vasomotor stimulant yet presented to the profession. It also stimulates the respiratory center and increases general metabolism and body temperature. The toxic dose for man is not known. The dilution should be at least 1-10,000 when the drug is given hypodermically. It seems safe to give an initial dose of 10 c.c. of the strong solution in 90 c.c. of normal salt. The injection should be slow, thus prolonging the effect of the drug.

**Molluscum Fibrosum of the Rectum in a Patient with the Typical Skin Lesion.**—A. B. Cooke declares that molluscum fibrosum is itself extremely rare. He reports a case in which the lower bowel was almost completely filled with polypoid tumors. Some sixty of the growths were removed. Examination of one of the specimens removed showed it to be identical in structure with the specimens of fibroma molluscum, which were examined from the great number upon the surface of the body. There was no evidence of adenoma or malignant epithelial growth.

*The Lancet, November* 14, 1903.

**Acute Fulminating Glaucoma.**—A. T. White reports a case of acute fulminating glaucoma ending in total blindness in eighteen hours after onset, and occurring during the course of severe syphilis, in an Italian laborer aged thirty-six years. This form of glaucoma is rare. No other cause in this individual case could be assigned.

**The Successful Treatment of a Few Cases of Lupus.**—C. R. Bowker reports seven cases. The main feature of his treatment consists in the injection of Koch's lymph and arsenic, combined with the thorough extirpation of the diseased tissue, and the local treatment must be adapted and varied to suit individual cases. If the wound left after incision be extensive small skin grafts will be found of great service in hastening the healing process; and he has had occasion in several cases to do plastic operations in order to restore the nose to something like its original shape, and in the cases in which this has been necessary the result has been fairly successful and with every satisfaction to the patient. The cases above quoted had all been treated previously by the method of scraping or burning, and there was no doubt as to the diagnosis

**A Group of Cancer Cases.**—W. G. Nash reports a series of cases as follows: Case A, male, rectal cancer, died in sixty-seventh year; case B, male, aged seventy-nine years, cancer of the tongue; case C, male, aged sixty-nine years, cancer of tongue; case D, male, aged sixty-seven years, cancer of the tongue; case E, male, aged forty-three years. The possible relation of these cases one to another was traced and the following facts were found: The widow of C, who was an innkeeper, stated that D and her husband were great friends, and that they frequently drank together out of a large tankard—in fact, before their illness they used to meet two or three times a week. D seems to have contracted the disease first, and on more than one occasion when drinking he complained of soreness under the tongue. The widow of C says that she always believed her husband caught it from D. B was no friend of the men previously mentioned, but occasionally as he passed through the village, he stopped at the inn kept by C to have a drink, and C's widow is certain that her husband and D never drank with B, but it is possible that the last mentioned drank out of a vessel which C and D had previously used. E lived in the same hamlet as B and came little in contact with C and D. He, however, frequented the same inn as B, but did not drink out of the same vessel. Soon after his illness started he used to take his own glass to the tavern. Finally it was discovered that A was a very intimate friend of both C

and D. They both often drank out of the same vessel, both at C's inn and at each other's houses.

**The Operative Treatment of Tuberculous Glands of the Neck.**—W. G. Sutcliffe notes the great practical advantage of making the lines of incision coincide with the natural creases of the neck. He believes that if an operation is decided on, the glands should in all cases be removed with their surrounding cellular tissue, and that the internal jugular vein so far from being divided and tied, as a routine measure, can almost always be avoided. The drooping of the shoulder caused by the division of the spinal accessory nerve is a very real deformity, causes considerable loss of power, and if the patient is a child is a source of almost certain lateral curvature. The author states that he has seen many old cases in which both the sternomastoid and the trapezius have atrophied and their appearance, with the longitudinal scars extending from the mastoid to the clavicle, has been a sufficient object-lesson, not only to try to treat the nerve with the greatest respect, but to put the incisions in the least visible region.

*British Medical Journal, November* 14, 1903.

**The Duration of Malta Fever**—William Hartigan believes that from three to six months may be expected as the duration of this fever. The writer has found salol very beneficial in the so-called typhoid stage. He gives the history of a patient who was suffering with this disease.

**Filariasis in Man Cured by Removal of the Adult Worms in an Operation for Lymph Scrotum.**—A. Primrose reports the case of a man aged forty-seven years. He had lived in Barbadoes all his life with the exception of a few short trips. Examination of the blood of the patient showed the embyro filariæ in large numbers. The whole scrotum was greatly thickened. At operation the greater part of the indurated scrotum was removed by an elliptical incision. An adult filaria was found in the scrotum. The operation resulted in freeing the patient of the filariæ as well as of the lymph scrotum. The interference with the lymph circulation is often very great in these cases.

**Case of Intestinal Infarction.**—H. Rothery Nutt describes this case. The patient was suddenly seized with intense abdominal pain. He became faint and fell to the floor, vomited and passed a motion. The abdomen was very slightly distended. Opium was given, and turpentine stupes applied to the abdomen. And all food was prohibited. Later in the day the abdomen became distended and tympanitic, and there was marked collapse. The temperature was subnormal. There was great pain and restlessness. At first the case was thought to be one of acute intestinal strangulation. Collapse was gradually increasing. The patient became steadily worse and expired. Necropsy was performed about ten hours after death. No obstruction could be made out. But the superior mesenteric artery was firm and round and the mesentery felt thickened. The writer concludes that it was remarkable that there was no diarrhœa or profuse hemorrhage from the bowels, and that the case terminated so rapidly.

**The Conditions that Simulate Pernicious Anæmia.**—Thomas Houston has examined a number of cases of profound anæmia, evidently the result of severe and prolonged hemorrhage, which, as far as their clinical symptoms were concerned, presented the features of pernicious anæmia with the exception that they were the result of hemorrhage, generally repeated small hemorrhages, as, for example, bleeding pies. It would appear that the characteristic blood features of pernicious anæmia, if they ever occur as the result of ankylostomiasis, must be an extreme rarity. The eosinophilia which constantly occurs in ankylostomiasis is not a feature of the blood of pernicious anæmia. As to bothriocephalus anæmia, Ehrlich admits that in some cases the blood presents the typical megaloblastic features of pernicious anæmia, but he regards this as due to the direct stimulation of the marrow by a specific toxin produced by the parasite. Pregnancy is occasionally accompanied by a severe or even fatal anæmia, which, from its symptoms, closely simulates progressive pernicious anæmia. In cases of malignant disease it appears that the blood changes are, as a rule, totally different from those of true pernicious anæmia.

*Deutsche medicinische Wochenschrift, November* 5, 1903.

**Ophthalmia Neonatorum and the Gonococcus.**—Schanz says that the observations on the ophthalmias of infants made soon after Neisser's publication on the gonococcus and which have been accepted without a cavil ever since were made upon insufficient statistics. Several recent investigators have found that inflammations may occur in the eyes of infants which clinically are not to be distinguished from the true blennorrhœa and yet in which the gonococcus can never be found. On the other hand, there is a whole series of other microorganisms capable of producing the typical picture of the gonococcus inflammation. This state of affairs is exactly opposed to that in the urethra, in which gonorrhœa is produced solely through the one specific organism, and the explanation offered is that the urethral mucous membrane and the conjunctiva are differently susceptible to microbic infection. This explanation is not wholly satisfactory, however, and it is evident that the question is not as simple as it at first seemed and will require much further study. Probably the class of pseudo-gonococci which has lately been erected will have to be demolished and these more resistant organisms considered simply as variants of the true species.

**One Hundred Cases of Diabetes in Their Relation to Tuberculosis and Arteriosclerosis.**—Croner finds that the records of the Berlin University Polyclinic corroborate the observations of most authors that these three diseases have more than a casual interrelationship. Forty-seven out of his hundred cases were either themselves tubercular or had tubercular relatives. Diabetes mellitus seems to be increasing in frequency and the belief that a hereditary predisposition underlies most cases is gaining credence. Clinical and experimental evidence shows that the two diseases, when existing concurrently, do not necessarily influence each other for the worse, but it is not unlikely that similar factors form the predisposing moment for each. The facts that the increase in diabetes is being attended by a decrease of tuberculosis and that the former is commoner in the upper classes, who are better protected against tuberculosis, and the latter is more frequently seen among the proletariat, are of interest in this connection. That the etiology of arteriosclerosis is also involved in the question is shown by the frequency with which the vascular lesion is found associated with diabetes. In many cases the glycosuria is the least important feature of the case and diminishes or disappears when the cardiac asthma, angina pectoris, etc., yield to treatment. Whether the sclerotic state of the pancreatic vessels or the disturbed nutrition or irritation of the glycogenic regions of the cerebellum is most concerned is still undetermined.

**Syphilis and Renal Surgery.**—Margulies points out the necessity for considering this condition in diagnosticating renal tumors and describes a case of his own. The patient was a woman of twenty-six who complained of pain and burning in the left renal region. She was much emaciated, cachectic, and had a constant slight elevation of temperature. In the position of the left kidney was a large, nodular, painful mass. Segregation of the urines by ureteral catheterization showed that the functional efficiency of both kidneys was practically normal, that of the left being somewhat inferior to that of the right. There was also evidence of a moderate degree of nephritis of the left organ. The most obvious assumption was new growth, probably sarcoma, though the physical signs and urinalysis were somewhat at variance with each other. The chief point against the diagnosis of new growth was the absence of blood in the urine. Other factors in the past history (miscarriages, pustular eruption, etc.) led to a diagnosis of renal syphilis, and a vigorous course of mixed treatment was begun. The patient's condition became steadily worse, however, and the temperature began to rise higher, so that an exploratory incision was made. The perinephritic tissues were found infiltrated with gelatinous material and the entire mass densely adherent to its capsule. A piece of tissue was removed for microscopical examination and its appearance pointed strongly toward syphilis, so that the mixed treatment was persisted in. Improvement soon began and in two months the tumor had entirely disappeared, only the faintest traces of albumen were present in the urine and the patient's general condition returned to normal.

*Berliner klinische Wochenschrift, October* 26, 1903.

**Vocal Fremitus in the Abdomen.**—Alexander has endeavored to confirm the reports of de Brun and Webber, who independently described vocal fremitus of the abdominal walls as a sign of certain conditions. De Brun observed it in cases of beginning ascites in which the fluid was just commencing to appear, and Webber in a perforated gastric ulcer with air in the peritoneal cavity. The author tested many similar cases of both sorts with negative results, and made experiments on animals also without once eliciting the phenomenon. He calls attention to the fact that the conditions which the above-mentioned writers say favor the transmission of vocal vibrations in the abdomen, *i. e.* the presence of fluid and of air respectively, are precisely those which in the chest cut them off completely, and neither observer has offered any explanation of this discrepancy with physical laws.

**A Contribution to the Study of Splenic Anæmia.**—Zypkin describes a case of splenic anæmia which presented a complex of appearances, putting it in the middle ground between pernicious anæmia and pseudoleukæmia. The red cells were 2,900,000 and the hæmoglobin 23 per cent. There was marked poikilocytosis, microcytes, megalocytes, and nucleated red cells were present. The leucocytes were normal in number, but their differential count showed polynuclear neutrophiles 54 per cent., eosinophiles 2½ per cent., large lymphocytes 27 per cent., small lymphocytes 12 per cent., mononuclear cells with non-granular protoplasm 6½ per cent. There was no lymphatic enlargement, but the characteristic splenic tumor was present. At the autopsy a high grade of fatty degeneration and infiltration of the liver cells was found, together with atrophy of the gastric and colonic mucosa. From this case, which stands somewhat closer to pernicious anæmia than to pseudoleukæmia, the author concludes that the sharp cut lines drawn between the severer blood diseases do not exist in fact, and that pernicious anæmia, splenic anæmia, and pseudoleukæmia form a chain leading up to either lymphatic or myelogenous leukæmia, according as lymphocytes or myelocytes predominate in the stage of pseudoleukæmia.

*Münchener medicinische Wochenschrift, Nov.* 3, 1903.

**A Contribution to Immunization with Ovary.**—Skrobansky has endeavored to arrive at the physiological significance of the ovary and corpus luteum by immunizing animals with these tissues. The reagent used was was the spermatic fluid of the same race as the ovary. Rabbits and guinea-pigs were immunized with the ovaries of white mice and of rabbits, and with ovarian tissue of the cows triturated in the liquor folliculi of the graafian follicles and with corpus luteum in physiological salt solution. It was found that the sera obtained in this way all stimulated the activity of the spermatozoa of the kindred animals to a marked degree. Rabbit serum immunized with beef ovary contained agglutinins for beef spermatozoa, but after the introduction of corpus luteum these did not appear.

**A Contribution to the Etiology of Pancreas and Fat Necrosis.**—Hess says that in many cases of fat necrosis of the pancreas, the course of events is as follows: Some, frequently unrecognizable, primary lesion of the pancreas causes pancreatic secretion to leave the cells and enter the intra and parapancreatic fatty tissue. The neutral fat is decomposed by the steatolytic ferment if the juice and soluble soda soaps are formed. By combination with calcium salts from the blood insoluble lime soaps are produced and may be recognized in the dead cells. The necrotic process now attacks also the neighboring pancreatic tissue. Any injury of the organ causing diffusion of pancreatic juice may result in more or less serious fatty and pancreatic necrosis. Extensive necroses are fatal; if less severe, a chronic indurative pancreatitis follows. In order to arrive at the nature of the primary lesion in such cases as the rapidly fatal so-called "pancreatic apoplexy," the author experimented on dogs with a view to finding what bodies entering the ducts from the stomach could produce such a condition. By injecting sterile olive oil into the pancreatic ducts he was able in every instance to produce results comparable to those observed in man. Large doses were followed in a short time by the picture of pancreatic apoplexy, smaller amounts caused an interstitial sclerosis of the gland. Oleic acid and soda soap gave fatal results, while glycerin and starch paste appeared to be harmless and paraffin produced only a mechanical lesion.

**The Treatment of Fresh Perineal Tears.**—Hegar believes that the customary view that all postpartum tears should be repaired immediately is open to considerable argument. The conditions for healing *per primam* are rarely good, the tissues are contused and their power of resistance to infection invalidated by the prolonged pressure, the patient is exhausted and anæmic, a state unfavorable to wound repair; in private practice, owing to the surroundings, lack of assistance, light, etc., aseptic operating is next to impossible, and the after-treatment is usually inadequate. A large proportion of puerperal infections immediately subside as soon as the perineal wound is opened up and allowed to drain, while statistics of even well-known clinics show a large percentage of failures to secure primary healing. In addition a goodly share of perineal tears do not damage the pelvic floor sufficiently to threaten its future integrity, and the author has collected a series of cases in which primary union and good functional result followed unsutured lacerations. Tears into the sphincter almost never turn out well after primary suture in private practice, and the scar tissue formed renders the secondary operation much more difficult. Episiotomy is to be condemned as useless and apt to produce serious subsequent deformity, but in delivering cases after a previous perineorrhaphy a section through the midline produces a wound in which the conditions for primary union are the most favorable. All cases must therefore be carefully studied before deciding in favor of primary suture.

*French and Italian Journals.*

**Goiter, Partial Thyroidectomy.**—Th. Jonnesco reports the case of a woman who for thirty-two years had suffered from a slowly developing goiter, which had recently been causing respiratory troubles, a sense of oppression, nervous tremors, palpitation, and cutaneous hyperæsthesia. A slight degree of exophthalmos was found, and the diagnosis was made of simple goiter with secondary symptoms of Basedow's disease. The goiter was voluminous and bilobed. Thyroidectomy was performed, a small portion of each lobe being left in place. The first effects were serious—intense cyanosis, frequent feeble pulse, asphyxia, temperature 100.4° F.; but these ceased on about the third day after operation. The Basedow symptoms disappeared more slowly, but completely, so that a year and a half after intervention there is no exophthalmos, no palpitation, no tremors, and the pulse is normal. There are some vague symptoms, especially muscular weakness, due probably to absence of the thyroid gland, and to be treated by the administration of thyroidine.—*Bulletin et Mémoires de la Société de Chirurgie de Bucarest*, May-June, 1903.

**Cardiorenal Cachexia.**—Louis Renon describes the symptoms of this condition which is the natural termination of interstitial nephritis, and of cardiosclerosis. It may be distinguished from cardiac cachexia by the fact that there is no œdematous infiltration of the limbs, no anasarca or ascites, no puffy and cyanosed face. The pallor may cause it to be mistaken for the cachexia of anæmia, but the cardiac and renal symptoms, the high arteral tension, and uræmic sweatings will determine the diagnosis. This once established, we should ascertain whether there is retention of chlorides, and if so, place the patient on the saltless treatment of Widal. Should this prove useless, the prognosis will be grave. Yet the author has obtained a delay of fatal symptoms for several weeks, by suppressing the milk treatment, and substituting water, for two or three days, gradually replacing it by rice water, barley water, vegetable bouillons without meat, and returning to a scanty milk diet. Powdered renal extract may be administered and small doses of trinitrin. Should severe symptoms set in again, the water diet may again be tried. These measures, however, are merely palliative, as a fatal result is sure to follow.—*Archives Générales de Médicine*, November 3, 1903.

**Lecithin.**—Henri Labbé writes of the therapeutic uses of lecithin extracted from the brain, or from eggs. He gives the physiological properties of the substance, its action on growth or metabolism, weight, appetite, urinary chemism, osteogenesis and hæmotapoietic processes, nerve elements and blood. In rachitis it has given excellent results, when taken in the place of phosphates. It can also be substituted for phosphates in phosphaturia. In neurasthenia and anæmia it is of great value, increasing the appetite, restoring physical strength, and causing an improvement of the general condition. Lancereaux and Paulesco have found it beneficial in diabetes, although it has no specific action on the production of sugar. In cachexias and in convalescence it has a field in restoring strength. In children it does not seem to produce especially good effects, except in lymphatism, while in the aged it is very useful in overcoming adynamia, improving the general condition, and strengthening the intellectual powers. In some cases it acts on the heart when digitalis produces no effect, and it increases the flow of urine. It should be tried in tuberculosis, for Claude and A. Zaky report that it causes marked general improvement.—*Revue de Thérapeutique*, November 1, 1903.

**Gastrotomy for the Extraction of Twenty-five Foreign Bodies.**—L. Monnier reports the case of a young man of twenty-two years, who seemed about fifteen, and who after being maltreated by an unnatural mother, in an epileptiform attack, attempted to commit suicide by swallowing a spoon, and then a number of other objects. Each ingestion was accompanied by sharp pain, the vomiting of bile and sometimes of blood. Nervous crises occurred finally, and after examination, an operation was decided on. Gastrotomy was performed, and there were removed from the stomach eight teaspoons, the end of a fork with three prongs, the handle of the fork, another fork handle, the fourth prong of the fork, nails, a needle, knife-handle, knife-blades, fork handle, shell hairpin, some small pieces of iron—in all twenty-five separate objects. The results of the operation were excellent. About three weeks later, the patient was able to take a sitting posture without pain, a thing which had for months been impossible. The author describes in full the operation and the after-treatment.—*Gazette des Hôpitaux*, November 3, 1903

# Book Reviews.

CHEMISTRY, INORGANIC AND ORGANIC, WITH EXPERIMENTS. By CHARLES LOUDON BLOXAM. Ninth edition rewritten and revised by JOHN MILLAR THOMSON, LL.D., F.R.S., Professor of Chemistry, King's College, London, and ARTHUR G. BLOXAM, F.I.C., Consulting Chemist and Chartered Patent Agent. Philadelphia: P. Blakiston's Son & Co., 1903.

THE progress of chemistry is so rapid that it is constantly more and more difficult to compress even the more important facts into one volume. Bloxam's Chemistry is, however, one of those which has successfully managed to do so. Many of the illustrations in former editions which have become obsolete have been weeded out of this one, and some new ones have been introduced. The position of carbon has been changed to follow immediately upon the elements hydrogen, nitrogen, and oxygen. On the whole, the standard of this edition seems to come fully up to that of its predecessors, as regards progress in both fact and theory. If one were inclined to criticise, it might be said that radium has allotted to it hardly its rightful amount of space, and from the editorial standpoint one or two minor points might be made. At any rate it is certainly an anomaly that the reference numbers in the table of contents should refer to paragraphs; while those in the index refer to pages But altogether the work is so well done that criticism touches only the smaller points.

TEXTBOOK OF DISEASES OF THE EYE. For Students and Practitioners of Medicine. By HOWARD F. HANSELL, A.M., M.D., Clinical Professor of Ophthalmology, Jefferson Medical College; Professor of Diseases of the Eye, Philadelphia Polyclinic; Ophthalmologist, Philadelphia Hospital; Consulting Ophthalmologist, Chester County Hospital, etc., and WILLIAM M. SWEET, M.D., Demonstrator of Ophthalmology, Jefferson Medical College Hospital; Assistant Ophthalmologist, Philadelphia Hospital; Associate in Ophthalmology, Philadelphia Polyclinic; Consulting Ophthalmologist, Phœnixville Hospital, etc. With chapters by CHRISTIAN R HOLMES, M.D., CASEY A. WOOD, M.D., D.C.L., and WENDELL REBER, M.D. With 256 Illustrations, including Colored Plates. Philadelphia: P. Blakiston's Son & Co., 1903.

THE volume is one of 532 pages. It is well printed on heavy paper, and is beautifully illustrated. Many of the illustrations are original. Almost all appear in the text, but there are a few colored plates representing the principal microorganisms found in diseased conditions of the eye. The illustrations of the fundus of the eye are few in number and are in black and white.

A chapter of forty-five pages is devoted to a description of the examination of the eye. It is followed by chapters on general optical principles and on the refraction of the eye. Separate chapters in logical order are devoted to the consideration of diseases of the various parts of the eye. Separate chapters in logical order are devoted to the consideration of diseases of the various parts of the eye, one to ocular symptoms in general diseases, and an appendix of twenty pages to a discussion of the color sense, methods of locating foreign bodies in the orbit and eyeball by the Röntgen rays, the economic value of vision, and a discussion of the instruments used in testing the muscles of the eyes. But little space is given to the discussion of theories, or to topics or measures the value of which is at all doubtful. There is no bibliography.

Some faulty statements are found, as, for instance, the one on page 27, in which it is said: "Should the candle-flame, upon which the eye is fixed, appear less brilliant, or be seen with greater difficulty than the second light, disease limited to the macular region or to the papillomacular bundle of fibers of the optic nerve may be presumed." While true in some respects, it does not cover the whole case, as diminution in the ability to perceive light in the line of fixation may be occasioned by an opacity of the nucleus of the lens from whatever cause, without in any way indicating disease at the posterior pole of the eye.

Another statement that should not be allowed to pass unchallenged is that on page 30: "Were the nasal field not restricted by the nose and the upper and lower fields by the roof and floor of the orbit, the entire circumference of the field would be equal to a hemisphere or even greater than a hemisphere" It is well known that the function of the temporal half of the retina is limited, and that the corresponding nasal half of the field does not in any case equal that of the temporal half of the field. The inaccuracies are not numerous and do not greatly detract from the value of the work.

Much space is given to the consideration of operative procedure, carrying the work into the domain of the experienced ophthalmologist—adding subject-matter for which the student has but little use.

The work will be valuable to all medical men who desire a brief statement of our present knowledge of ophthalmological subjects.

HYPNOTISM: ITS HISTORY, PRACTICE, AND THEORY. By J. MILNE BRAMWELL, M.B. Philadelphia: Lippincott & Company, 1903.

THE author of this volume on hypnotism is favorably known to the medical profession as a temperate but withal consistent advocate of hypnotism as a therapeutic measure. His contributions to the literature which have appeared heretofore chiefly in *Brain*, have been characterized by qualities that commend them to the careful consideration of neurologists and general practitioners.

Mr. Bramwell devotes the first two chapters to the history of hypnotism, giving the credit for its introduction and establishment of respectability to Elliotson and Esdaile, Braid and Liébault, all of whom were, he maintains, more or less martyrs to what they believed to be truth. The author's method of inducing hypnotism is practically that of the Nancy school. His experience has led him to the same conclusions as those of most writers on the subject of the susceptibility to hypnosis. The nervous, ill-balanced, and hysterical are the most difficult to influence, while healthy people who possess the power of concentrating their attention, he finds to be the easiest to hypnotize.

The author's conclusions regarding the value of hypnotism in comparison with other forms of treatment are temperate and sound. He maintains that hypnotism is not a universal remedy It is a branch of medicine, and those who practice it use it in conjunction with other forms of treatment. The author very properly points out that the diseases which frequently respond to hypnotic treatment are often those in which drugs are of little or no avail, and, as a matter of fact, it is in cases of this sort, in patients with obsessions, or fixed ideas, for instance, and in the functional nervous disorders associated with states of mental depression that hypnotism has its largest field as a therapeutic agent. One-third of the book is devoted to the theories of hypnotism, and here there is nothing new, merely recapitulation of the views of others, some of whom are not entitled to speak much less to be heard upon the subject. Mr. Bramwell thinks that although this subliminal consciousness theory does not satisfactorily explain all the problems of hypnosis, we are at all events indebted to it for a clearer conception, not only of the condition as a whole but also of many of its component parts. Taken altogether, the book is not an important contribution to the subject of hypnotism, save that it sets forth dispassionately some of the results obtained by the author in the treatment of disease by hypnotism. It lacks in criticalness, it lacks in true perception of pathological problems, and it lacks in conciseness. Nevertheless, it is a safe book to recommend to those who are desirous of obtaining a knowledge of the applicability of hypnotism from the point of view of a physician who believes in it and who still does not believe that it is the whole thing therapeutically.

THE NATURE OF MAN. Studies in Optimistic Philosophy. By ELIE METCHNIKOFF, Professor at the Pasteur Institute. Edited by P. CHALMERS MITCHELL, M.A., D. Sc. Oxon. New York and London: G. P. Putnam's Sons, 1903.

THE author takes the view that the nature of man is in itself the chief obstacle to his happiness, and that by virtue of his construction and social instincts he is at variance with his environment. He designates these qualities as "disharmonies," and attempts to prove from numerous scientific facts how they influence his physical comfort and ultimate welfare.

Starting with the bold assumption that man is a miscarriage from the anthropoid ape and is endowed with a superabundant amount of intelligence, he proceeds to prove that it will be necessary for him to go through many more evolutionary changes in anatomical structure before the proper goal of his existence can be reached. For instance, the "disharmonies" of the digestive apparatus, the uselessness and dangers of the appendix, the curbed functions of the reproductive organs, the perversion of the menstruation, the "disharmony" between the age of puberty and the age of nubility, and the decline of the family instinct, are quite exhaustively discussed. Science has done much to mitigate the misfits of conditions with the exactions of advancing civilization, but much more remains to be accomplished along similar lines.

In the contemplation of old age and death much is said of the philosophy of meeting it with becoming resignation as the final relief of all human suffering and the end of all trouble. The inability to reconcile advancing decrepitude with the natural ending of life and to view dissolution with becoming submission to the inevitable is one of the many problems this author attempts to solve.

The ideal conception is the abandonment of all fear, re-

sembling the state of mind of one who goes quietly to sleep after the work of the day. Such a condition would imply "the cultivation of the instinct of death" as a counterbalance to the "instinct of life." This condition of mind and body would obtain, according to the author, when the aged can secure a perfectly "natural death" by gradual and painless dissolution. There is much learning and argument expended in support of the theories of the distinguished professor, and to the student, lay or medical, who is given to philosophical reasoning, there is much food for thought in the ingenious and scholarly manner in which the general subject is discussed. An earnest follower of the doctrines of Darwin, Huxley, and Spencer, he makes the most of their teachings in the elucidation of his views.

A Textbook of Obstetrics. By Barton [Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania; Gynecologist to the Howard, the Orthopedic, and the Philadelphia Hospital, etc. Fourth Edition. Revised and Enlarged. Philadelphia, New York, London: W. B. Saunders & Company, 1903.

The profession is already so familiar with the well-known work that the announcement that it has reached a fourth edition so soon will hardly occasion surprise, except at the capacity for work of the author. He emphasizes in the preface his views that "the physician in general practice must be equally well informed in both branches of Gynecology." Hence he gives more attention than ever to the diseases of the pelvic organs following childbirth. Much new material has been introduced and many new illustrations. The criticism might be offered that this part of the book is practically a repetition (or rather anticipation) of the companion work on diseases of women, notably the sections on extrauterine pregnancy and injuries to the perineum and pelvic floor.

Part III, on normal labor, is full of valuable suggestions. The keynote is contained in the sentence: "The invalidism of women following childbirth could be enormously reduced, a reproach to medicine could be removed, if this plan (of thoroughly examining women after convalescence) were uniformly adopted."

That the revision is really a rewriting of the volume is evident from the foot-notes, which show that no important contribution to the literature of obstetrics has been overlooked, while the prominence given to surgery is in itself a proof of the enormous advance in this department during the past few years.

Introduction to the Study of Malarial Diseases. By Dr. Reinhold Ruge of the Imperial German Navy. Translated by P. Edgar, M.B., C.M. Edin., District Surgeon, Teluk Anson, F. M. S., and M. Eden Paul, M.D. Brux., M.R.C.S., L.R.C.S. London: Rebman, limited, 1903.

In this monograph all that is necessary for any but a specialist to know of the various forms of malaria, their complications and sequelæ, is accurately and carefully described. The book was intended, the author explains, for the use of the ship's surgeon and the colonial surgeon who might need advice but who did not want a tome of undue size. Dr Ruge has met this requirement well, and has covered the entire subject, including a full account of the parasites and of the malarial mosquito with a description of the methods of study of the same, within less than 140 pages. In controversial matters the author naturally takes the German side, and at times is not fair toward Marchiafava and other of the Italian observers, and in his therapeutic recommendation also he merely echoes Koch's suggestions. The illustrations, including plates of photographs of the malarial parasites and mosquitos, are good.

A Textbook of Diseases of Women. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania; Gynecologist to the Howard, Orthopedic, and the Philadelphia Hospitals. Philadelphia, New York, London: W. B. Saunders & Company, 1903.

As stated in the preface, this book is a companion volume to the author's textbook on obstetrics. We can only indicate the salient points in this latest addition to the literature of gynecology, since its merits can be appreciated only by a careful perusal. The arrangement of the subject matter is the usual one. The book is divided into twelve parts, an introductory chapter on examination being followed by sections on anomalies, diseases of the external genitals and vagina, the uterus, tubes, and ovaries, the pelvic connective tissue and peritoneum, and the urinary tract, concluding with a description of the technique of gynecic surgery. The chapter on examinations is clear and practical, the illustrations being original and beautifully executed.

Diseases and injuries of the external genitals and vagina are well handled in Parts III and IV, the descriptions and illustrations of operations on the perineum and pelvic floor being especially good.

Under diseases of the urinary tract considerable attention is paid to the ureters and also to nephropexy. With the author's conservative views on floating kidney, we are entirely in accord.

Nearly one hundred pages are devoted to technique, this chapter being in some respects superior to the descriptions in many textbooks. The unusually large number of illustrations renders the book most helpful to the student.

A Textbook of Obstetrics. By J. Clarence Webster, M.D. (Edin.), F.R.C.P.E., F.R.S.E. Professor of Obstetrics and Gynecology in Rush Medical College, in Affiliation with the University of Chicago; Obstetrician and Gynecologist to the Presbyterian Hospital; Obstetrician to the Chicago Lying-in Hospital and Dispensary; Consulting Obstetrician, Chicago Maternity. Philadelphia, New York, London: W. B. Saunders & Company, 1903.

In this work the anatomy and physiology of pregnancy have been brought thoroughly up to date, and the plates in the chapter referring to them are especially good. In speaking of the obstetric examination, the author lays special stress on the importance of obtaining information as far as possible by the external examination. In our opinion, this point cannot be too strongly emphasized, for the time has come when internal examination in labor is necessary only in comparatively few instances. The author is to be commended for the chapter on the conduct and management of labor. We cordially endorse his views, with reference especially to the duties of the obstetrician in the management of the first stage of labor. The author maintains correctly that "in the great majority of cases the only examination necessary is the abdominal," and that "nothing is more to be deprecated than the routine vaginal examination of parturient women," for "it is a frequent cause of infection." We do not agree with the author, however, when he recommends that the finger be introduced into the rectum to facilitate the birth of the head. The author's remarks on asepsis and antisepsis are admirable, the chapter on eclampsia is full of good material, and, taken as a whole, the book can be cordially recommended as a safe guide to the general practitioner.

Functional Diagnosis of Kidney Diseases; with Especial Reference to Kidney Surgery. By Dr. Leopold Casper, and Dr. Paul F. Richter. Translated by Dr. Robert C. Bryan and Dr. Henry L. Sanford. P. Blakiston's Son & Co., Philadelphia, 1903.

The title given to the English translation is without meaning. The German authors have styled their work "Functionellen Nieren-Diagnostik," which rendered into English would be, diagnosis of kidney function. Casper and Richter are pioneers in this line of research, and their book is devoted to a full discussion of the importance of determining the kidney function in diseased states of these organs, and to the method by which such knowledge is ascertained. The authors lay much stress upon the value of cryoscopic examinations of the separated urine, drawn at the same time by the ureteral catheters.

The work of Casper and Richter is excellent as far as it goes. But when nephrectomy is contemplated we desire to know of the opposite kidney, not only its health or disease, or its functional capacity while the diseased organ is still in place, but especially its capacity for functional compensation after the removal of the one organ. For a supposedly well-functionating kidney may lack the power of compensation; while a diseased organ may be fully able to compensate for its fellow after the latter's removal. This estimation of the functional *compensating* power of the one organ we have no means of obtaining.

The publishers and translators are to be congratulated for rendering into English the excellent work. The translators have done their work well, and the book should be read by all who enter the field of kidney surgery.

Lessons on the Eye. By Frank L. Henderson, M.D., Ophthalmic Surgeon to St. Mary's Infirmary and to the Christian Orphans' Home; Consulting Oculist to the St. Louis City Hospital. Philadelphia: P. Blakiston's Son & Co., 1903.

In this, the third edition of the author's manual for the express use of undergraduate students, the same general plan as heretofore has been adhered to. Each chapter is arranged as a lesson to be studied and memorized by the student.

There have been added new cuts and quite a little supplementary matter to bringing the book up to the present state of knowledge of the subject. The chapter on general therapeutics is especially thorough and all the latest remedies are fully referred to. As now presented to the profession, this attractive and comprehensive little book is of value not to the undergraduate alone, but also to the general practitioner for quick reference.

SECTION ON SURGERY.

*Stated Meeting, Held November 4, 1903.*

ROBERT T. MORRIS, M.D., CHAIRMAN.

**A Hand Grapple for Use with Bed-ridden Patients.**—Dr. FREDERIC GRIFFITH gave a blackboard demonstration of this piece of mechanism. He said that it was employed in the hospitals throughout Europe for the comfort of patients. It consisted of what might be called a hand-grapple suspended above each bed. It had excited his wonderment that such an appliance had not been introduced before into this country, because this contrivance added so greatly to the patient's comfort. The invention consisted of a wooden handle, from ten to twelve inches long, and one and one-eighth, or one and one-quarter inches, in diameter. It might be turned from an oak stick or improvised from a broom-handle. Spliced in the middle of the handle was a six-foot manila rope. Support from above was by means of a strong wrought hook-bracket set in the wall behind the bed. A piece of welded iron made up an arm which swung at a radius of at least three feet; or when the bed was at a proper distance from the wall the handle swung above and between the patient's elbows when he was in the natural supine position. By means of a shackle and block the handle would be placed within easy reach, about one foot above the reclining body. When to use only temporary a screw-hook might be driven into a joist in the ceiling above the patient instead of swinging a bracket, although this would necessitate a longer rope. He said it was wonderful the increase of comfort that was given these patients during the hours of night especially.

**Specimen of Stump Neuromata.**—Dr. MOSES KAKELS presented this specimen, which was pathological because it interfered with repair. One of the most important external factors in their causation he thought to be bacterial influences and inflammation. Stump neuromata he believed to be rare when aseptic principles of surgery were carried out successfully. The specimen was removed from a patient who had been injured by a circular saw and who had entered the City Hospital. The wound suppurated and would not heal primarily, and the patient left the hospital after several weeks' treatment. The painful stump made him resort to morphine for its relief. The stump was later incised and about two inches of the nerve removed. A sinus was left. The patient went to the country. Within two weeks a cellulitis developed. When last heard of he complained of pain and had again resorted to the use of morphine for its control.

Dr. H. D. COLLINS had never seen any statement that stump neuromata could result from traumatism as well as from bacterial infection. He believed that where an amputation had been deliberately performed and in selected cases, with primary union resulting, such a condition rarely followed. If the amputation was traumatic and healing occurred by primary union or without any extensive infection, then be believed that one might find stump neuromata.

**Fracture of the Neck of the Femur.**—Dr. SAMUEL LLOYD presented a man who had come under his observation last December. Seven months previous he had fallen from a car, striking on his hip. He could not get up. He was taken into the hospital and a diagnosis made of fracture of the neck of the femur. A plaster-of-Paris splint was at once applied, and in four days it had to be removed on account of the pain. The injured limb was then placed in a wooden splint and the patient was kept in the hospital for two months, when he was discharged. When Dr. Lloyd saw him in December he found there was a lack of union in the hip; he also found some telescoping showing that there was no impaction. The *x*-ray showed a fracture of the neck of the femur. As seven months had elapsed since the accident, the patient was given the choice of wearing an orthopedic apparatus or else submitting to operation. Nailing the fragments was decided upon, and the operation was performed on the 20th of December. An incision was made below the anterior superior spine of the ilium and the capsule exposed and the periosteum raised. A fracture of the femur was found at the junction of the neck and shaft and a second fracture through the neck was noted, making a triangular piece of bone. The neck was completely separated from the shaft. The fracture was both intracapsular and extracapsular. The triangular piece of bone was removed. The diaphysis and the head of the bone were properly chiseled and the two surfaces adjusted. A second incision was made over the trochanter and, the two fragments being held in proper position by an assistant, an old-fashioned wire nail, previously prepared, was driven through the fragments, so approximating them. Both fragments were proven to move well together. The dressings were applied and a spica bandage used from the head to the axilla. Dr. Lloyd said this case was particularly interesting because of the double fracture of the neck of the femur, one piece of the neck being loose. A second point of interest was to be found in the condition that supervened after the nailing of the fragments. Dr. Lloyd had operated upon seven cases of old fracture of the neck by this method of nailing and had succeeded in all but one, this patient dying of sepsis. He said that he had found great difficulty in all his cases in keeping the wound aseptic, because of the manipulation of the splint as the swelling went down. Soiling sometimes occurred from the urine and even the fæces. It was interesting to note the amount of motion in the hip and the amount of limitation. The nail had been left *in situ* six weeks. In three of his cases the fracture was well up toward the head of the bone, and only a small piece left of the head, and the capsule had fallen over the upper fragment that, to get to the acetabulum, he had to cut the capsule away.

Dr. H. M. SILVER asked if Dr. Lloyd would use this method in the aged who were not in good condition.

Dr. Lloyd answered that it is was doubtful if he should on account of the traumatism.

Dr. ROBERT T. MORRIS had two good results in old people. It seemed to him that there was one factor in particular that was not discussed in textbooks, the influence of the synovia upon the formation of callus. He believed one reason for failures in obtaining union of the neck of the femur was because the synovia was not drained; by so doing one gave the callus an opportunity to become organized.

Dr. ELSBERG asked why Dr. Lloyd found difficulty in keeping the parts aseptic. He had done a great many bone operations and had not experienced any such difficulty. He left on the dressings fully two weeks; if the wound was then aseptic it would remain aseptic, granulation tissue would form and prevent absorption, etc.

Dr. Lloyd said he desired to get primary union and not touch the dressings for a long time, but the class of patients found in hospitals could not have impressed upon them the importance of cleanliness and, therefore, it seemed almost impossible to keep the wounds aseptic in this class of patients.

**Iliac Adenitis.**—Dr. RAMÓN GUITÉRAS read this paper reporting four such cases as follows:

CASE I.—The patient was an Italian, twenty-six years old, who, five years ago, had malaria, the spleen becoming enlarged. Since then he had never been ill. Three months ago he had a swelling in the right iliac region and right groin, which was quite painful. An examination in the hospital showed a mass, two and a half by one and a half inches exactly under the inguinal canal. The external genitals were normal. The urine was normal. The epitrochlear and cervical glands were normal. The temperature ranged from 99° to 102°, the pulse from 76 to 98. The patient was admitted to the hospital with a diagnosis of appendicitis, but no tumor was found. An incision re-

vealed a mass of enlarged glands in the inguinal region and these were excised. The inguinal canal was opened, but no tumor or any lesion found. Below the canal was found an indurated mass. The pathologist reported the specimen as being one of simple adenitis.

Case 2.—The patient was a laborer, forty-two years old, who entered the hospital with a dull pain in the left iliac region. The tumor became more painful and larger. The physician made a diagnosis of fecal impaction. His previous history was negative. He had no wounds or ulcerations of the lower extremities. A tumor was found, three inches by three, in the left iliac region over Poupart's ligament. The glands in the inguinal region were slightly enlarged. His temperature was 99.4°, and his pulse 90. The pain subsided when poultices were applied. The inguinal glands were removed and there was no indication of suppuration. Syrup of the iodide of iron was administered and counter-irritants applied externally and the mass subsided.

Case 3.—The patient was a man, twenty-seven years old, who had a mass in the right iliac region, which had grown steadily during the past three weeks. Examination revealed a hard mass parallel to Poupart's ligament; it was flat on percussion. It grew inward toward the median line and extended to the internal inguinal ring. His temperature was 102° and pulse 100. Poultices were applied for one week and the temperature then was from 99° to 101° and pulse from 72 to 100. The leucocyte count ran from 72,000 to 94,000, and yet the patient did not complain of feeling sick. An incision was made over the mass on the inner side of Poupart's ligament, the inguinal canal was opened and the cord drawn to one side. Pus escaped from the wound and the fingers passed into a large abscess cavity well outlined. After the operation the leucocyte count fell, and two weeks later the temperature and pulse became normal.

Case 4.—This patient was a man, forty years old, who had a swelling in the lower half of the left side of the abdomen which had been growing for three weeks. History was negative. Examination revealed a tumor situated above Poupart's ligament in the left iliac fossa, resembling a variety of inflamed appendices. There was no fluctuation. The temperature ranged from 99° to 100° and the pulse from 88 to 94. An incison was made over the tumor and an abscess cavity found. This was drained and treated in the usual way and healed within two or three weeks. Then there was a recurrence of the pain and temperature. A fragment of gland supposed to be tubercular was dissected away. The patient left the hospital with a sinus remaining.

Dr. Guitéras said that iliac adenitis was a rare condition, and that there was some relation between it and bubo. Two of the cases had buboes and at the same time there was no history to which buboes and the swollen inguinal glands could be attributed. In a large experience with such cases of bubo associated with venereal disease he said he had never seen cases in which iliac adenitis followed the bubo which was associated with venereal trouble. There seemed to be some relation between iliac adenitis and the pelvic organs through the internal group of iliac lymphatics. In one case of sarcoma he had discovered a direct extension from a sarcomatous prostate along the entire iliac glands to the external iliac glands, which resulted in œdema of the lower extremity. In many cases he believed the iliac glands broke down and discharged below Poupart's ligament, the condition being diagnosed as psoas abscess. In many cases there were no signs discovered in the spinal column to indicate disease there. Where these abscesses heal fairly rapidly he thought that, in all probability, there were instances of iliac adenitis. In two cases the enlargement of the iliac glands disappeared after the inguinal glands were removed. In the other two cases the iliac glands broke down and suppurated, while there was no involvement of the inguinal glands. With regard to the question of treatment, he believed that the results in the four cases reported showed that the treatment by poultices and excision of the inguinal glands were to be preferred and had been proven to be of value. One might think that, as the glands were situated extraperitoneally one might do an extraperitoneal operation and remove the glands; this he said would necessitate a much more extensive operation and, if the glands were found to be suppurating, a long time might be required to heal by drainage and packing; it would also be found a difficult space to pack.

Dr. John Rogers, Jr., thought that iliac adenitis was a comparatively rare affair and rarely diagnosed in the hospitals. He took exception to what Dr. Guitéras stated that he seldom saw a bubo follow iliac adenitis. A study of the anatomy of this region showed there were a number of glands here that was not iliac. The bubo glands drained the lumbar region, and infection of the iliac region may come from the inguinal or sacral region.

Dr. Torek said that when suppuration occurred, and the pus raised the peritoneum, an incision close to Poupart's ligament would carry one easily behind the peritoneum. But where there were no suppurating glands by a large incision, one could dissect the peritoneum off and follow the glands to a considerable height. In one instance he had to make a secondary incision in the lumbar region to obtain more perfect drainage.

Dr. H. D. Collins said that opening the lumbar region for the purpose of draining the iliac glands was a difficult procedure, because they lay below the level of the sacroiliac synchondrosis, making lumbar drainage almost as difficult, from a physical standpoint, as through an opening over Poupart's ligament. No difficulty would be encountered if one made an incision high up on the surface of the abdomen, one and a half inches above the level of Poupart's ligament; then go in and do an intermuscular separation as in appendicitis. By so doing one could get a generous incision.

Dr. Torek said that he spoke of a posterior lumbar incision *not* for purposes of extirpating the inguinal glands, but for purposes of drainage.

Dr. Guitéras closed the discussion and said that the inguinal glands consisted of two groups, superficial and deep, and they were quite freely connected. If one operated upon a case of bubo due to venereal trouble, the deep group may frequently be involved. The deep group extended along Poupart's ligament, and continuous with these glands were the iliac glands. The iliac group emptied into the lumbar glands and, for that reason, he spoke of the rarity of the complication of iliac adenitis with inguinal adenitis. In his paper he said he intended to state that if he went through the abdominal wall and then found the anterior and posterior parietal layers of the peritoneum were adherent, he would, of course, go into the abscess cavity; but, if the peritoneum was not adherent, he would not try to empty the cavity by that route, but he would close the incision and then dissect around the peritoneum, making an incision opposite Poupart's ligament.

**The Treatment and Management of Postoperative Tuberculous Cases.**—Dr. S. A. Knopf read this paper. It seemed to him that any patient who was operated upon for tuberculous disease would require the individual after-treatment in the same sense that it was necessary to individualize in the treatment of diseased lung or larynx in different persons. He then considered what could be done in a general way for the patient, operated upon for some tuberculous lesion, from the moment of leaving the table. Placing the patient in a well-equipped tent was most commendable. He advocated a change of bed morning and night. So soon as the condition of the wound permitted an afebrile patient should be allowed to leave the bed and rest in a reclining chair; as convalescence progressed the patient should be placed in a half-tent for the rest cure in the open air.

He advocated respiratory exercises if they could be performed without causing local pain, or general discomfort, or disturbing the wound or dressings. They should never be taken if the patient was tired and never to the extent of tiring the patient. They should never be taken after a hearty meal, nor in any overheated room, nor dusty or vitiated atmosphere. Deep breathing after capital operations lessened the dangers of hypostatic pneumonia. The speaker then demonstrated on himself the four or six breathing exercises which he taught as a means of prevention and cure for tuberculosis. Solar therapy could best be carried out by exposing the patient's body to the direct rays of the sun, keeping the head in the shade. Headache, or feelings of discomfort, were signals to stop the sun baths. If elevation of temperature followed, then the sun baths should be stopped. He said the hydrotherapy should be individualized to every tuberculous patient. In the majority of cases sponging the body with tepid or cold water may be permissible To get the skin and nervous system accustomed to the use of cold water for continued use, he begun with a friction of pure alcohol for a few days, then took half alcohol, and half water for the same number of days, and finally resorted to the use of cold water. Absolute bodily and mental rest in pure fresh air was an important part in the treatment of feverish tuberculous patients. A temperature of 100° or more was an indication for rest in bed; from a fraction above normal to a littleless than 100° rest in the reclining chair. Except in cases of intestinal tuberculosis, he did not advocate any ironclad dietary list for any tuberculous patient with a good digestion. Zomotherapy, or the administration of raw beef or its juices, was of great value in all types of tuberculosis. The occasional appearance of a tapeworm should not prohibit its use. Cod-liver oil he considered to be indispensible, especially among the poor where good cream and butter were not plentiful. Massage he recommended in all cases of malnutrition, poor circulation, and if thoracic muscles are atrophied. Cough should be controlled as far as possible by discipline, urging the patient always to suppress the dry cough; sips of cold water or milk were often helpful in this endeavor. Patients should be enjoined to hold their handkerchiefs before the mouth during the so-called dry cough, sneezing, etc., and he considered this precaution particularly important while the wound was exposed for re-dressing. A very essential factor in the psychical treatment was to keep the patient occupied and with something which had his cure for its ultimate purpose. Do not allow him to become despondent or to brood over his disease. He advocated very strongly seaside sanatoria. Germany, France, Italy, Holland, and the Scandinavian countries have a large number, with schools attached, for tuberculous and scrofulous children, and they reported from 50 to 75 per cent. cures. For patients recovering from operation for tuberculous arthritis, osteitis, and even peritonitis, a prolonged sojourn at the seacoast, with the judicious use of cold and warm salt-water applications, seemed to act marvelously. He believed there was a large field for practical philanthropy, and he asked that their influence be felt to induce statesmen and philanthropists to create a number of permanent sanatoria for the treatment of this class of patients.

Dr. TOREK emphasized the fact that we should not consider these tuberculous patients ready to leave our care after the operation; the after-treatment was sometimes far more important than the operation. In surgical work we remove only a certain focus of the disease, and, in fact, the operation was really only the beginning in the cure.

Prof. T. STORIE DIXON, Sidney University, Australia, said that originally there were no cases of tuberculosis in Australia. Sir Arthur Renwick told him that thirty years ago there was not a case of tuberculosis in Australia. To-day one death out of every fifteen occurred from tuberculosis. This showed the extreme infectious nature of the disease. He believed that much could be done to help these patients if the respiratory exercises and proper massage were more often employed.

Dr. Knopf made the announcement that Mr. John Seeley Ward, Jr., member of the Board of Managers of the New York Association for Improving the Condition of the Poor, had just returned from Europe, where he had visited several sanatoria for the treatment of tuberculous and scrofulous children. This association contemplated estabishing seaside sanatoria, in all probability near the coast of Long Island.

## NEW YORK NEUROLOGICAL SOCIETY.

*Stated Meeting, Held October 6, 1903.*

PEARCE BAILEY, M.D., PRESIDENT.

**Partial Paralysis of the Platysma Myoides Following Typhoid Fever.**—Dr. EDWIN G. ZABRISKIE presented a girl of seventeen, a cigarette-maker. Following an attack of typhoid fever five years ago a sinus formed in connection with the lower jaw on the left side. On coming under observation recently it was found that there was paralysis of the left platysma myoides, and that this muscle failed to respond to electrical stimulation.

**Extirpation of Gasserian Ganglion for Neuralgia.**—Dr. WILLIAM HIRSCH presented a woman who had been operated upon one year ago for the relief of trigeminal neuralgia by the removal of the Gasserian ganglion. Microscopical examination showed that the ganglion had been completely extirpated. The neuralgia had been completely relieved. There was no analgesia anywhere. Remak claimed that one result of paralysis of the trigeminal nerve was a pushing of the lower jaw over toward the affected side, associated with partial subluxation. This patient showed only a slight deviation. In this woman the perception of a sweet taste was somewhat uncertain, that for sour was lost, and the taste for bitter was perverted. The electrical reaction of the muscles on the affected side was perfectly normal, but the effect of the current as regards taste had not been noted.

**Congenital Multiple Angiomata.**—Dr. M. ABRAHAMSON presented a boy of fifteen years, born in Russia, after a very prolonged labor. He was cyanotic at birth, and was resuscitated with difficulty. When two months old the mother first noticed a small mass behind the left ear; another appeared on the left side of the neck when two years old after a fall. Since then new ones had appeared. Epistaxis had been frequent, but there had been no hemorrhages from the other mucous membranes. There were a number of these swellings, or angiomata, notably in the tongue and lip. There was an angioma in the retina of the right eye. There were apparently no angiomata in the liver and spleen. This boy showed both of Virchow's types—cavernous and fissural. The course of the disease in this case was not in accordance with any of the theories that had been advanced to explain such cases.

Dr. WILLIAM M. LESZYNSKY presented a boy of eleven years who had been born at full term by forceps without suspended animation. He had never had convulsions. He seemed perfectly well up to nine months ago, when he began to bend forward when walking. When first seen, on March 9, 1903, his general health was found to be good. The knee-jerks were unobtainable, and the limbs became rigid in various positions. No evidence of organic nervous disease was discovered, and a few days later the knee-jerks were elicited. He was discharged after sixteen days, walking perfectly well, but he was readmitted to hospital in July in a condition similar to the original one. The speaker believed at first that the attitude was imitated, and that subsequently it became a habit. Although the boy walked in a doubled-

up position with the head almost touching the floor, he could hang upon a horizontal bar without special difficulty. When in bed he lay like other children. There were no objective sensory disturbances of hysteria. For want of a better name he would call it a case of hysteria. This habit had persisted, and remained even when he was not observed. There was, of course, exaggeration and a certain element of simulation.

**The Movements of Superior Intercostal Muscles in Hemiplegia, and the New Hemiplegic Symptom.**—Dr. L. PIERCE CLARK presented this paper. He said that Gowers expressed the generally accepted opinion regarding the respiratory movements in hemiplegics when he said that in ordinary respiration the two sides of the thorax moved equally, but that in extraordinary respiration there was often less expansion on the paralyzed side. In 1895 Hughlings Jackson stated that in hemiplegics the superior intercostal movements were greater on the paralyzed side during ordinary or automatic respiration, whereas in forced respiration the movement was greater on the sound side. The speaker said that he had examined 161 cases of hemiplegia with regard to this point, with the result that this sign was found to be uniformly present. In destructive lesions of the internal capsule causing hemiplegia, the cortical inhibitory control over the medullary respiratory center of the paralyzed side was largely destroyed, and, accordingly, the inhibited medullary center acts excessively in automatic respiration. The experiments of W. G. Spencer demonstrated the presence of an inhibitory center situated just outside of the olfactory tract, anterior to its junction with the temperosphenoidal lobe, and of an acceleration center apparently located in the posterior portion of the sensory motor area of the cortex. The location of the inhibitory center would lead one to expect it to be damaged in vascular lesions, especially of the middle cerebral, affecting the integrity of the capsular fibers. The fact that the superior intercostals of the paralyzed side were innervated through cerebral fibers ending on spinal centers in the anterior horns of the cord, and the more or less marked damage of the same would account for the general motor loss of volitional acts on the hemiplegic side. The respiratory center could be demonstrated in all muscles bilaterally susceptible of both automatic and volitional movements.

**The Advisability of Supplementing the Words Degeneration and Degenerate by Deviation and Deviate.**—Dr. G. L. WALTON of Boston presented a paper with this title. The definitions given by a number of well-known writers were cited to show that a degenerate was one exhibiting certain deviations from the normal type. The words "deviation" and "deviate," therefore, seemed to him to be more accurate, and less objectionable, because independent of all theories. Referring to the hereditary aspects of the question, attention was called to the tendency of similar parents to produce inferior degenerates and of dissimilar parents to produce beings superior to their immediate ancestors. The term "degenerate" he would limit, so far as possible, to the lowest grades of constitutional defect, and avoid altogether the anomalous term "superior degenerate."

Dr. HIRSCH said that about ten years ago he had himself pointed out the apparent misuse of the term degenerate. The definition which he had given at the time of degeneration was, "a mild development of the psychical organ." The term, superior degenerate, was not originally applied in the way in which it was referred to in the paper, *i.e.* a degeneration of a lesser degree, but rather that the higher faculties of certain individuals were degenerated. The word "deviation," unfortunately, was not one which could be used internationally, and this, in itself, constituted a serious objection to its adoption, although there could be no doubt about the term being superior to degeneration.

Dr. C. L. DANA said that he was very much in sympathy with the purpose of this paper, and that his own views regarding degeneration did not differ very much from those of the author. He understood that Dr. Walton wished to continue the use of the term degeneration in connection with somatic changes. About eight years ago, in an address before the Academy of Medicine, the speaker said he had defined a degenerate as "one who differed from the average standard of the family from which he sprung," and suggested that there were two classes of degenerates to whom the term could be applied without any implied opprobrium. One of these was the class spoken of in the paper as the "superior degenerate." He thought the term "variation" could be very properly applied. He was of the opinion that in superior degenerates and inferior degenerates, in imbeciles, and even in the higher types there was a degenerative tendency in the germoplasm, and that the family was very apt to die out.

Dr. B. SACHS thought that if degeneration was too severe a term, deviation was too mild a term, for it could not be looked upon as representing anything morbid. After all, the only objection to the term, degeneration, was in its application to the so-called superior degenerate, and the vast majority of the persons to whom the term degenerate had been applied showed a distinctly downward tendency.

Dr. JOSEPH COLLINS said that the substitution of terms suggested by the author of the paper did not seem to him a wise move, but an effort to incorporate those terms into medical literature to express certain conditions often included under the terms degeneration and degenerate should be encouraged. Because some of the indecent newspapers saw fit to use the term, degeneracy, merely as a synonym for moral profligacy, and particularly sexual perversion, was no reason for the scientific world to feel called upon to change this term. Even in scientific circles it seemed to him that the term, degenerate, was used altogether too frequently. He believed that the usual tendency in both superior and inferior degenerates was downward from the normal moral standard, and that this notion was rightly reflected in the definitions quoted.

Dr. EDWARD D. FISHER said that his understanding of the term, degenerate, carried with it the idea of a departure from the moral standard, although there were possibly other forms of degeneracy in which the moral aspect did not enter. The term deviation seemed to him entirely inadequate.

Dr. Walton, in closing, emphasized the fact that it was intended, not to displace degeneration, but to furnish a synonym which might prove useful He saw no harm in the milder word sometimes being used to include the more severe, just as delinquent was meant to include criminal. He agreed with Dr. Sachs that deviate was too mild a word to supplant degenerate, and this was not his intention. If no objection were made to substituting deviate for superior degenerate, the ground would be practically covered. He agreed with Dr. Collins in deploring the elaboration in literature of the individual moral deviations, but this tendency could not be prevented. If we could limit our use of these terms to scientific circles, the word, degenerate, as understood in those circles, would satisfy all requirements, but the subject had now become a matter of general interest.

**A Case of Cerebral Diplegia or So-called Muscular Pseudohypertrophy.**—Dr. NATHAN reported this case. The patient was a large, well-developed boy of ten years. On standing, there was decided lordosis. When lying down, he was apparently unable to raise himself. There was good power in the hands, and the thighs could be flexed without difficulty. He walked with the typical spastic gait. The knee reflexes and the electrical reactions to both currents were exaggerated. The mental development was nil, largely owing to neglect. The case differed from those of pseudohypertrophy in infantile paralysis previously reported in several respects. This

was the only case on record, so far as known, in which pseudohypertrophy occurred in a case of so-called spastic spinal paralysis, all previously reported cases were hemiplegic. There were no athetoid movements in this case. The measurements showed that besides the pseudohypertrophy there was enlargement of the left thigh and arm.

Dr. L. P. CLARK said that the condition had not been first described by him, as stated in the paper, but by Bernhard about twenty years ago. Gowers had reported a number of cases about one year later. The case reported here was evidently quite rare. Athetoid movements were noted in only about one-half of the cases, and neither this nor spasticity was sufficient to account for the cases, because this was also frequently absent.

Dr. C. L. DANA said that he did not think the diagnosis could be made solely upon the large calves, because this was frequently present in diplegics.

Dr. B. SACHS said that he quite agreed with the last speaker regarding the enlargement of the calves, and suggested that the only positive way of making the diagnosis would be by excising a piece of muscle and demonstrating the characteristic changes.

Dr. J. COLLINS said that if the contention were that pseudohypertrophic paralysis with spasticity had not been recognized, he would say that during the summer there had been in his clinic a case of typical pseudohypertrophic paralysis in which the spasticity was apparently as great as in the case just reported. Although there was profound spasticity, particularly of the adductors, there was no exaggeration of the knee-jerk, and no Babinsky—in other words, there were no indications of disease of the pyramidal tracts. The case had been looked upon as a peculiar form of obesity before coming to the clinic.

Dr. NATHAN said that it had not occurred to him that there was any doubt about the diagnosis. The history was typical of cerebral paralysis. The child was born asphyxiated, and had convulsions repeatedly up to the seventh year. It began to walk when three years old, and had always walked with difficulty. The only symptom of pseudohypertrophic paralysis was the enlargement of the calves. It was interesting to note that the left side was larger than the right.

---

*Stated Meeting, Held November 3, 1903.*

PEARCE BAILEY, M.D., PRESIDENT.

**A Case of Muscular Dystrophy.**—Dr. J. RAMSAY HUNT presented a woman, forty-one years of age, suffering from muscular dystrophy. The first symptoms began about six months ago with a certain heaviness in the legs, and at the end of a year she experienced difficulty in going up and down stairs. She came under observation about two years and a half ago, at which time there was paralysis of the adductor groups of muscles on both sides, and also of the iliopsoas groups. The arm muscles were normal, except that the elevators were slightly weak. The family history was negative. She had borne four healthy children. There were no evidences of involvement of the pyramidal tract. The electrical reactions were normal. The special interest of the case centered in the localization of the affection in the adductor and iliopsoas groups of muscles.

Dr. JOSEPH FRAENKEL referred to a case that he had seen, in which the condition had apparently developed rather suddenly following a pregnancy. This peculiar localization in the adductor and iliopsoas muscles made the diagnosis at first rather difficult. He had found, in the literature, mention of a case which was looked upon as a progressive muscular atrophy, and not a dystrophy, but the other features did not support that view.

**Studies on the Periosteal Perception of Vibrations.**—Dr. EDWIN G. ZABRISKIE read a paper with this title. He said that the best method of testing this sense was by means of a tuning fork set in vibration, and then placed firmly over the bony prominences where there was the least amount of tissue between the bone and the skin. The fork selected for this purpose was that devised by Dr. Dench, giving sixty-four vibrations per second, because of the power of such a fork to send the vibrations through a considerable layer of tissue. The results were controlled by means of a fork having 512 vibrations. In making the observations the intelligence of the patient must be well considered; even intelligent people were apt to confuse the pressure of the fork with the vibrations. It was well to first place the fork where the vibrations would be plainly felt, as over the cranium, thus impressing upon the patient the kind of sensation to be noted. The lesions studied were divided into three groups, viz.: (1) Those of central origin, (2) those of the nerves themselves, and (3) those of the bones and joints. The first group contained by far the greatest number of cases studied, and the most interesting ones were tabes dorsalis, cerebrospinal syphilis, the lesions producing Brown Sequard's symptoms, and hemiplegia. When there were profound disturbances of the integument there might be slight or no change in the periosteal perception. Most commonly there was a wider distribution, or a more profound disturbance of the periosteal perception, than that of the integument. Sometimes there were only certain areas of one bone over which the periosteal perception was lost. There were only three cases with the Brown Sequard symptoms that were studied, and, hence, no definite conclusions could be drawn. As yet he had been unable to establish a definite relation between the periosteal perception of vibrations and the position sense. Some cases of sciatica presented an interesting condition. In several of these there was no loss of periosteal perception of vibrations or of the position sense, although there were definite disturbances of cutaneous sensation. In about one-half of the cases there was a diminution of the periosteal perception on the affected side. In the cases of alcoholic neuritis, with slight involvement of the cutaneous sensibility, none showed any change in the periosteal perception. In the case of beginning acromegaly there was no disturbance of the position sense. In the joint cases when there was evidence of definite absorption of the bone, there was loss of vibration confined to the affected bone area. In a case of chronic arthritis of the hip joint the perception of periosteal vibrations on the affected side of the pelvis were decidedly diminished. In the cases of arthritis deformans only one showed any disturbance of the position sense, and that case also exhibited marked cutaneous disturbances over the left arm and right leg, and over these areas the vibrations were less plainly perceived. In a case of cerebellar tumor the position sense was profoundly disturbed. There were no cutaneous disturbances or changes in the periosteal perception of vibrations. The speaker said that he had examined seven or eight well-defined tubercular joint lesions, yet none of these showed any change in the periosteal perception of vibrations. He had himself been unable as yet to come to any conclusions.

**Mental Defect and Shock.**—Dr. PEARCE BAILEY reported the following case: The patient was a victim of the tunnel disaster in New York city on January 8, 1902. Prior to the accident he had been an active man without hereditary taint, and with no history of syphillis or alcoholism. He was fifty-eight years of age, and had built up a large and lucrative business. The lower part of both his legs were crushed, and after about one hour he was taken away in an ambulance. At this time he lost consciousness, and did not regain it until after he had reached the hospital. The patient gave an accurate and vivid account of the accident, which showed very well the terrible mental strain he had undergone. At the hospital it was found that the only injuries he had received were compound fractures of both bones of both legs. The next afternoon he became stuporous. He had been first seen by the speaker on January 15 while in a private hospital. There was no paralysis of any cranial nerves, or of the hands. Sometimes he would make inarticulate answers to questions; sometimes he would not answer at

ill. A few days later he appreciated the fact that his mind was cloudy. He improved slowly. On February 8, however, he became delirious from the onset of erysipelas. When seen again, on June 13, he had left the hospital. He was still sleeping but little; his appetite was good, but he was entirely unable to endure physical or mental effort. Many simple words he did not understand, and many others he could not read correctly. His writing was very tremulous and imperfect. He made mistakes in counting and in simple arithmetical problems. His memory of the time preceding the accident was perfect, and also that immediately after the event, but from shortly after his admission to the hospital memory was very defective. When seen again on February 11, 1903, his condition was much the same. His speech was somewhat thick, and there was distinct interference with the intellectual mechanism of speech. Much that he read he did not understand. The last examination was made on October 15, 1903, and it showed improvement in many ways, but no material change in the fundamental condition. He had returned to business, but was unable to take any active part in it. There had been no fixed delusions. Exaggeration, the speaker said, he was sure played no part in the case, and he had taken but little interest in his suit for damages, which had been settled without coming to trial. His mental state was entirely distinct from the delusional one of hysteria; the condition resembled neurasthenia somewhat, but was distinct therefrom. His condition resembled more the pathological mental states occurring directly as a sequence of infectious diseases, surgical operations, and exhaustion generally.

Dr. JOSEPH COLLINS congratulated the author on his brilliant presentation of this topic, but he did not quite understand Dr. Bailey's reason for speaking of the case as one of mental shock. If there ever was a case of profound physical shock, this case seemed to him to be an example of it. The occurrence of compound fracture of both legs, associated with so much agony, would seem to bear out this view. That mental shock was an accompaniment went without saying. This patient had gone into a collapse delirium for a few days, and had then reëntered that state after his removal to another hospital. It was safe to assume that his physical system experienced disturbances of metabolism; in other words, that an autointoxication had been engendered which, acting upon his deplorably weakened mental condition, had resulted in a state which, as the author had well said, was observed after surgical operations. The mental disorganization was manifest more especially in the higher intellectual spheres, such as was commonly seen after collapse delirium. He would be interested to know what prognosis had been given in this case; also whether any examination had been made to determine whether his associative faculties had been equally disturbed.

Dr. HENRY RAPEL asked what was the patient's physical condition at the present time.

Dr. ADOLPH MYER said that this report reminded him of a patient whose history he had already reported in a paper, in which were reported thirty-one cases of traumatic insanity. His patient had been greatly shocked as a witness of the subway explosion in Boston. He had not been physically injured by the explosion. The patient had been under observation in hospital for about one year after the accident, and had been discharged practically well. The symptoms presented were those of neurasthenic incapacity. He was a roofer by occupation, but after the accident could not continue this work for fear of falling. One day, subsequently, a fire in the neighborhood put his mental equilibrium to a test, and after this he drifted into a sort of hysterical state, in which memory became very imperfect. Despite this, he enlisted in the army, and was only released from active duty on the request of the physicians. On first coming under the speaker's observation, it was thought that he had general paralysis, but, on further examination, it was evident that he was neurasthenic. He gradually recovered his mental and physical health. In the thirty-one cases referred to, the question of mental shock or fright had been frequently met with. These cases were most apt to be associated with hysteroid phases, and were found not infrequently with a history of dementia præcox. Since fright was a condition which could not be easily produced experimentally, one was forced to depend altogether upon casuistic reports, and for this reason the report under discussion was especially valuable.

Dr. EDWARD D. FISHER said that the extent of the injury was not by any means an indication of the resulting mental symptoms. There was something more than the pain which was the active cause of the resulting neurasthenia or dementia. It was a daily experience that persons suffered severe injuries without any resulting abnormal mental state. A case was mentioned in which a man of about sixty had been caught in a railroad accident, and although many had been injured he had entirely escaped. He had been in good health, and had not had nephritis or diabetes. About six months or more after the accident he passed into a state of neurasthenia, and the accident became a constant topic of conversation. His mental and physical power slowly decreased, and within a year he died. This case could only be explained, to Dr. Fisher's satisfaction, by the shock: he would not be satisfied to explain it by any theory of autointoxication. He understood from Dr. Myer that autopsies on such cases yielded very meagre results.

Dr. J. FRAENKEL said that it was a well-known clinical fact that epileptics, in spite of the injuries they frequently received, practically never developed traumatic psychoses. He recalled a case, seen a few years ago, with Dr. Collins. When first seen by the speaker, the man was in an acute mumbling delirium, in which he was talking about falling from a scaffold. The question at once arose as to whether the patient was in full possession of his senses before the accident. Further inquiry showed that the patient lost consciousness at the moment that he was on the scaffold. The case was finally proved to be one of postepileptic delirium. His personal belief was that physical shock alone was not sufficient to produce psychoses of the functional variety, and that it was necessary for the production of a post-traumatic psychosis to have the patient in the full possession of his faculties at the time of the accident. This was a particularly important point in connection with medicolegal inquiries. In the foregoing statement he included all purely physical injuries, even injuries to the head.

Dr. J. ARTHUR BOOTH said that the case reported by Dr. Bailey was especially interesting because he understood that the effect of litigation could be eliminated. The fact that the condition had persisted for two years pointed to organic changes. He would like to know whether there had been vomiting shortly after the accident.

Dr. COLLINS said that he had had several cases bearing very closely upon the statement made with regard to the patient's mental condition at the time of the injury. He did not wish to be understood as saying that in Dr. Bailey's case the mental symptoms were the result of metabolism of any sort. He would like to know what were the physical signs at the present time.

Dr. Bailey closed the discussion. He said he could not agree with Dr. Fraenkel fully with regard to fright being an essential element of traumatic hysteria. He recalled very distinctly a case in which it was stated that the hysteria did not occur before the accident, and that the patient was asleep at the time of the accident, and, hence, consciousness was in abeyance. It was, of course, very difficult to separate physical and mental shock. In the State of New York the Court of Appeals had decided that for a claim for damages there must be shown to be physical injury as well as mental shock. It was his opinion that his patient suffered chiefly from the mental anguish, the physical suffering being insignificant in comparison with

the mental shock. The man's appearance was that of one suffering more from mental shock. Dr. Bailey thought the prognosis at the present time was bad. The man was distinctly neurasthenic, and although he could for a time associate and recognize, he very quickly became fatigued, and certainly presented absolute loss of mental faculties. His physical condition was, on the whole, good. His face flushed and paled as was common in neuræsthenics. There had never been any vomiting.

## Books Received.

*While the* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

GYNECOLOGICAL NURSING. By NETTA STEWART. 12mo 174 pages. Illustrated. Oliver & Boyd. Edinburgh Price, 2s. 6d.

DAS TRACHOM ALS VOLKS- UND HERRESKRANKHEIT. By D. J. BOLDT. 8vo, 240 pages. August Hirschwald, Berlin.

INTRODUCTION OF THE STUDY OF MALARIAL DISEASES. By DR. REINHOLD RUGE, P. EDGAR, M.B., and M. EDEN PAUL, M.D. 8vo, 138 pages. Illustrated. Rebman, Ltd., London, England.

MODERN METHODS IN THE SURGERY OF PARALYSES. By A. H. TUBBY, M.S., and ROBERT JONES, F.R.C.S.E. 8vo, 311 pages. Illustrated. Macmillan & Co., London.

MANUAL OF PRACTICAL ANATOMY. By D. J. CUNNINGHAM. 8vo. Third edition in two volumes. J. B. Lippincott Co., Philadelphia.

THE MEDICAL DIRECTORY OF NEW YORK, NEW JERSEY, AND CONNECTICUT. Volume V. 12mo, 1850 pages.

TRANSACTIONS OF THE AMERICAN OTOLOGICAL SOCIETY, sixty-sixth annual meeting, Washington, D. C. Volume VIII, Part II. 8vo, 341 pages. Illustrated. Published by the Society, New Bedford, Mass.

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY. 8vo, 256 pages. Ira C. Evans Co., Printers, Concord, N. H.

ANNUAL REPORT OF THE SUPERVISING SURGEON-GENERAL OF THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE OF THE UNITED STATES FOR 1900 AND 1901. Two Volumes. 8vo, 736 and 652 pages. Illustrated.

THE PRACTICE OF MEDICINE. By JAMES TYSON, M.D. Third edition. Square 8vo, 1242 pages. Illustrated. P. Blakiston's Son & Co., Philadelphia, Pa.

THE MEDICAL ANNALS OF MARYLAND. By E. F. CORDELL, M.D. 8vo, 887 pages. Illustrated. 1799-1899.

STATE OF NEW YORK STATE, COMMISSION IN LUNACY, FOURTEENTH ANNUAL REPORT. 8vo, 1091 pages. The Argus Company, Albany.

A TEXTBOOK OF THE PRACTICE OF MEDICINE. By JAMES M. FRENCH, M.D. 8vo, 780 pages. Illustrated. William Wood & Company, New York. Price, extra muslin, $4.00; leather, $4.75 net.

GENERAL PATHOLOGY, OR THE SCIENCE OF THE CAUSES, NATURE, AND COURSE OF THE PROCESSES OF DISEASE. By Dr. ERNST ZIEGLER. Edited by ALFRED S. WARTHIN, M.D. 8vo, 760 pages. Illustrated. William Wood & Co. Price, muslin, $5.00; leather, $5.75.

PRACTICAL GYNECOLOGY. By E. E. MONTGOMERY, M.D. Second revised edition. 8vo, 900 pages. Illustrated. P. Blakiston's Son & Co., Philadelphia. Price, $5.00 net.

TEXTBOOK OF THE DISEASES OF THE EYE. By DRS. H. F. HANSELL and WM. M. SWEET. 8vo, 532 pages. Illustrated. P. Blakiston's Son & Co. Philadelphia, Pa. Price, $4.00 net.

AN ATLAS OF HUMAN ANATOMY. By CARL TOLDT, M.D. First section. Square 4to, 160 pages. Illustrated. Rebman Co., New York

TRANSACTIONS OF THE AMERICAN OPHTHALMOLOGICAL SOCIETY, VOL. X. Part I. 8vo, 196 pages. Illustrated. Published by the Society.

LESSONS ON THE EYE, FOR THE USE OF UNDER-GRADUATE STUDENTS. By Frank L. Henderson, M.D. Third edition. 12mo, 205 pages. Illustrated. P. Blakiston's Son & Co, Philadelphia.

A TREATISE ON ORTHOPEDIC SURGERY. By ROYAL WHITMAN, M.D. Second edition, 8vo, 848 pages. Illustrated. Lea Brothers & Co.

## Medical Items.

**Contagious Diseases—Weekly Statement.**—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending November 21, 1903.:

| | Cases. | Deaths. |
|---|---|---|
| Measles | 307 | 17 |
| Diphtheria and croup | 284 | 44 |
| Scarlet fever | 171 | 8 |
| Smallpox | 4 | ... |
| Varicella | 82 | ... |
| Tuberculosis | 399 | 134 |
| Typhoid fever | 68 | 13 |
| Cerebrospinal meningitis | ... | 4 |

**Health Report.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended November 21, 1903:

SMALLPOX—UNITED STATES.

| | | | CASES | DEATHS |
|---|---|---|---|---|
| California, Los Angeles | Nov. | 1–7 | 1 | .. |
| Louisiana, Baton Rouge | Oct. | 24–Nov 7 | 2 | .. |
| Massachusetts, Lawrence | Nov. | 8–14 | 1 | .. |
| Mississippi, Natchez | Oct. | 25–Nov. 7 | 3 | .. |
| Nebraska, Omaha | Aug. | 1–31 | 3 | .. |
| New Hampshire, Manchester | Nov. | 8–14 | 2 | .. |
| New Jersey, Camden | Nov. | 8–14 | 1 | .. |
| New York, Buffalo | Nov. | 2–9 | 1 | .. |
| Ohio, Cincinnati | Nov. | 6–13 | 9 | .. |
| Youngstown | Nov. | 8–14 | 12 | .. |
| Pennsylvania, Philadelphia | Nov. | 8–14 | 34 | 1 |

### LESIONS OF THE EYE WHICH OCCUR IN THE COURSE OF DISEASES OF THE HEART, THE BLOOD-VESSELS AND THE KIDNEYS.*

BY CHARLES STEDMAN BULL, A.M., M.D.,
NEW YORK.

**Ocular Lesions Occurring in the Course of Diseases of the Heart and Blood-vessels.**—Under this heading we must consider certain abnormalities in the circulation of the blood current, as well as actual lesions of the walls of these vessels.

Under normal conditions, the intraocular pressure is to be regarded as one of the functions of the intravascular blood-pressure. Any abnormality of this blood-pressure may give rise to circulatory phenomena within the eye, which are visible with the ophthalmoscope.

In pronounced general anæmia we often find a very pale, almost white, optic papilla, with very narrow pink vessels. If there be distinct diminution of the intravascular tension, the slightest pressure with the finger on the eyeball will cause pulsation in the retinal arteries, and may cause entire disappearance of the veins. If these conditions last for any length of time, spontaneous retinal hemorrhages may appear, which are very prone to recur. On the other hand, retinal hemorrhages, associated with high arterial tension, are significant of widespread arterial degeneration. These retinal hemorrhages, after absorption, leave white patches behind them, and in such cases actual vascular disease must be assumed.

If the blood-pressure suddenly falls, as after great loss of blood, the intraocular pressure acts as an obstruction to the retinal circulation. The arteries pulsate and become narrower in caliber, the optic disk becomes pale, the field of vision becomes concentrically narrowed, everything grows dark before the patient, and then syncope ensues. The loss of sight is usually bilateral, though it may be confined to one eye, and may amount to complete blindness, which may be permanent, or the vision may improve, but, as a rule, complete restoration of vision does not occur. The ophthalmoscopic signs of this variety of amblyopia are often negative at the outset, though there may be a pale optic disk and very narrow vessels. If the vascular tonus is not restored, more or less extensive atrophy of the optic nerve results, occasionally preceded by neuritis and papillitis, with white patches in the retina and hemorrhages. All these symptoms may be found after profuse hemorrhage from whatever source. Amaurosis after hemorrhage is however rare, and is not apt to occur except in persons who are not otherwise healthy. The symptoms usually occur several days after the hemorrhage, and the resulting amaurosis is often due to a hemorrhage within the optic nerve. Under certain predisposing conditions a process of necrobiosis develops in the walls of the vessels during this defective circulation, which gives rise to the subsequent hemorrhages. If the hemorrhage is far back in the optic nerve, the ophthalmoscopic symptoms may be for some time negative and in these cases a central scotoma in the field is sometimes found. In actual organic disease of the heart and blood vessels the ocular symptoms are more constant and well-marked.

Venous hyperæmia of the retina accompanies cardiac affections in which the return of the blood toward the heart is obstructed, as in valvular lesions and in fatty heart.

In *aortic insufficiency* one of the very constant symptoms is an alternate reddening and pallor of the optic disk. There is almost invariably a pulsation of the retinal arteries synchronous with the radial pulse. As a result of the compensatory hypertrophy of the left ventricle, the blood-pressure is greatly increased during systole and diminished during diastole, on account of the reflux of blood through the insufficient valves. If, however, the aortic insufficiency is accompanied by a stenosis of the aorta, the retinal arterial pulse may be absent. In other words, in aortic regurgitation there is a sudden visible increase in the pulse wave in the retinal arteries, and spontaneous arterial pulsation is especially frequent, and is absent only when aortic constriction exists, or when the regurgitation is small. General venous congestion as the result of cardiac disease will be seen in the eye, usually in the retina, but sometimes also in the conjunctiva. In the last stages of *mitral disease* retinal pulsation is an almost constant phenomenon.

In *dilatation* of the *heart without valvular disease* marked hyperæmia of the retina and greatly enlarged and tortuous retinal veins have often been observed. In *fatty heart* we meet almost always with extensive disease of the retinal vessels and numerous hemorrhages in the retina.

As a general rule it may be stated that retinal hemorrhages, without signs of inflammation, are a sign either of increased blood-pressure, such as occurs in cardiac hypertrophy and in valvular lesions, or of disease of the retinal vessels, or of morbid conditions of the blood. They are very common in cases of insufficiency of the mitral and tricuspid valves. It is well known that disease of the heart or of the blood vessels may give rise to *thrombosis* and *embolism* in the eye. *Rheumatic endocarditis* is one of the most frequent causes of embolic processes in the eye, the emboli being generally benign, acting mechanically and exciting no inflammation. But in *ulcerative endocarditis* we have a variety of pyæmia, and the septic cocci may lead to hemorrhages or thromboses and abscess in various parts of the eye, especially the retina, chorioid and conjunctiva. Numerous capillary emboli and miliary abscesses have been found in the retina and optic nerve, and these are prone to recur.

*Emboli* of the *choroid* do not give rise to any marked symptoms, because of the comparatively large size of the chorioidal vessels, and the numerous anastomoses which prevent any great disturb-

*Read by invitation before the New York Academy of Medicine under the auspices of the Ophthalmological Section, November 5, 1903.

ance of the circulation. An embolus of a chorioidal vessel looks like a patch of chorioretinitis, forming a whitish prominent spot, over which the retinal vessels may pass. The field of vision shows a scotoma corresponding to the situation of the embolus. When the resulting retinal opacity has disappeared, a patch of atrophy is seen surrounded by irregular pigmentation. The ultimate vision is but little impaired, and may be entirely restored. Several of these embolic foci may be formed in the same eye.

*Embolism* of the *central retinal artery* or its branches runs a much more severe course, because the retinal artery is a terminal artery and has but few capillary anastomoses. An embolism of the main trunk of the central retinal artery may be the first indication of an insidious endocarditis, and thus the ophthalmoscope may afford the first evidence of cardiac disease. If the embolus lodges in the trunk of the central artery, sudden blindness will occur. The arteries appear empty, the veins narrow, with occasional interruption of the column of blood, and the optic disk is pale. Diffuse opacity of the retina soon comes on, most dense around the papilla, and allowing the region of the fovea to shine through as a cherry-red spot. Generally the blindness is permanent, though occasionally the retinal circulation is partially restored through anastomoses at the entrance of the optic nerve, and this may be assisted by gentle systematic massage of the eyeball. The optic disk becomes atrophic, and the retinal arteries are sometimes converted into connective tissue cords. In embolism of a branch of the central artery, the opacity of the retina is confined to a limited area, and the blindness is limited to a corresponding portion of the field. Numerous hemorrhages may appear in the retina, to be absorbed at a later date. The embolus itself may be visible with the ophthalmoscope. Patches of fatty degeneration in the retina are not infrequently met with later, as well as partial atrophy of the optic nerve.

It has been for years a well-recognized fact that ocular symptoms may be produced either directly in the eye, or indirectly from the brain, by extensive disease of the walls of the blood vessels, such as *atheroma*, *arteriosclerosis*, or *fatty degeneration*. These changes in the vessels are very frequently seen in the retina, but occur much more extensively in the chorioid and may be seen in both arteries and veins. The walls appear thickened or surrounded by a white border (periarteritis or periphlebitis). In places the thickening is so marked as to give a spindle shape to the vessel, and the lumen is correspondingly narrowed, sometimes to complete obliteration. As the disease progresses, the vessels become obliterated or changed into white cords, dilatations alternating with constrictions, so that the appearance resembles that of miliary aneurysms. As a result of this degenerative change hemorrhages into the retina are very common, occurring spontaneously or on very slight provocation. They are also met with in the chorioid, and are very common in the ocular conjunctiva, especially in persons beyond middle life. These hemorrhages are usually absorbed, but in the retina an extensive white discoloration is left. They frequently recur, and inasmuch as disease of the vessel-walls in the eye points to a similar condition of the vessels throughout the body, these hemorrhages are of great prognostic importance, and in elderly people at least are a warning signal of impending apoplexy.

*Arteriosclerosis* may be regarded as the cause of that variety of glaucoma called hemorrhagic, or to be more exact, this variety of glaucoma is developed in eyes in which the blood vessels are diseased.

By some authorities endarteritis of the internal carotid artery is regarded as a cause of cataract, and in many of these cases the diseased condition of the common carotid artery may be detected by careful palpation.

It is well known that this vascular degeneration is often caused by syphilis. It is frequently met with in renal disease, and in the absence of positive evidence of cardiac disease, it may excite a suspicion of diabetes, for retinal hemorrhages due to vascular degeneration are not infrequent in this disease. They may be said to be common occurrences in chronic diabetes, and are of unfavorable prognostic significance.

*Atrophy* of the *optic nerve* often results from arteriosclerosis of the internal carotid and ophthalmic arteries.

*Aneurysmal disease* of the *thoracic aorta*, *innominate* and *internal carotid* arteries, due to degeneration of the vascular walls, are sometimes accompanied by ocular symptoms.

In *aneurysm* of the *aorta* or *innominate* artery, vasomotor and oculopupillary symptoms are often found on the corresponding side. Later, these initial irritative symptoms give place to ptosis, myosis, and enophthalmos. Such aneurysms may also give rise to retinal pulsation. If the aneurysm involve the internal carotid artery, it may cause unilateral optic neuritis or papillitis, and if such an aneurysm grows toward the orbit, there may be developed the symptoms of pulsating exophthalmos. Such an aneurysm has also been known to cause total paralysis of all the muscles of one eye, and, also anæsthesia of the lids, eyebrow, and conjunctiva from paralysis by pressure on the ophthalmic division of the fifth nerve.

The retinal arteries are occasionally the seat of aneurysmal dilatation, but these are rare, probably on account of the support afforded to the vessels by the vitreous humor. When they occur they are significant of similiar conditions in the small arteries of other organs. They may involve the primary branches of the central retinal artery, or they may be miliary aneurysms of the small capillaries. It is proper here to consider the eye symptoms in cerebral apoplexy and embolism arising from arteriosclerosis of the cerebral vessels or from endocarditis. In many cases of cerebral apoplexy, conjugate deviation of the eyes occurs as a transient symptom. If the hemorrhage is in one of the cerebral hemispheres, the accompanying paralysis is not alternate because the lesion is above the decussation of the oculomotor nerves, and therefore the eye muscles are paralyzed on the same side as the extremities. The deviation of the eyes is of diagnostic importance in locating the apoplexy. If the eyes turn toward the paralyzed side, the lesion is in the pons on the opposite side. If the deviation is toward the sound side, the lesion is above the pons on the same side as that toward which the eyes turn.

It cannot be positively stated from the presence of paralysis of the ocular muscles *alone* what the nature of the cerebral lesion is. But a sudden lesion, occurring immediately or within a few hours, and causing oculomotor paralysis, is always a vascular one, either a hemorrhage or an embolism. If there are no pupillary symptoms, the lesion is an embolism. If there is spastic myosis followed by mydriasis during a seizure, the lesion is apoplexy.

Reference to lesions of the carotid artery naturally leads to a consideration of the subject of *thrombosis* of the *cavernous sinus*. These throm-

boses are of two kinds: *infectious*, arising from caries of the petrous bone, and *non-infectious*. A consideration of the first variety has no place here. In the non-infectious, marantic thrombus of the cavernous sinus we meet with paralysis of the motor oculi nerves, dilated and immovable pupil, anæsthesia of the parts supplied by the trigeminus, pronounced venous stasis of the retinal veins, with numerous hemorrhages, and impairment of sight from pressure on the optic nerve. If, in addition, there is œdema of the lids and protrusion of the eyeball, the process is in the vicinity of the orbit.

**Ocular Lesions Occurring in the Course of Diseases of the Kidneys.**—All forms of organic disease of the kidneys may give rise to certain lesions of the eye and its adnexa, but they are much more frequent and significant in the general condition known as albuminuria.

*Œdema* of the *eyelids* is met with in acute nephritis and in the late stages of chronic nephritis, and œdema of the lower lids may present itself before the development of any other symptom. The same condition has been observed, though rarely, in the ocular conjunctiva, where it has received the name of chemosis. Hemorrhages into and beneath the conjunctiva have been occasionally observed in the course of a retinitis, and very rarely have been known to precede the deeper lesion.

*Iritis* has been reported as due to nephritis, in the absence of any other cause, and as the vessels of the iris are often extensively diseased in albuminuria, it is evident that a very slight exciting cause would give rise to iritis. Similar changes are known to coexist in the chorioidal vessels, but the lesions in the chorioid, which might be expected to be revealed by the ophthalmoscope, are generally masked by the pigment epithelium of the retina. Arteriosclerosis of the chorioidal vessels is very common in retinitis albuminurica, and occasionally we meet with chorioidal hemorrhages ending in circumscribed atrophy of the chorioid.

Hemorrhage into the vitreous occasionally occurs, always single and coming on without the patient's knowledge.

*Lesions* of the *ocular muscles*, due to disease of the kidneys, have been repeatedly denied by many writers, but they undoubtedly occur, and more frequently than is usually believed. Many years ago I made it a rule in my practice to examine carefully the urine in every case of suddenly occurring paralysis of the ocular muscles. The cause of such a paralysis is probably a hemorrhage in the region of the nerve roots or nuclei. These paralyses usually recover rapidly, but often relapse. They are among the terminal symptoms of the renal disease, and indicate changes in the cerebral vessels similar to those found in the retina.

The most frequent lesions of the eye associated with renal disease are intraocular, and are found in the retina and optic nerve. There may be a simple though well-marked *congestion* of the optic disk, and retina, or a *retinitis* with or without patches of *exudation*, or *optic neuritis* with or without *hemorrhages*, or an actual choked disk or *papillitis*, differing in no respect from papillitis due to other causes. These lesions of the optic nerve or retina often confirm the diagnosis previously made of nephritis in cases in which the other symptoms, such as slight headache, digestive disturbance, etc., have been vague. In many cases, in which the general constitutional symptoms have been so slight as to escape notice, the ophthalmoscopic examination gives the first intimation of the existence of disease of the kidney, which is already far advanced.

There are two forms of *retinitis albuminurica*. (1) Degenerative inflammation of the retina, occurring with contracted kidney and characterized by retinal hemorrhages and whitish patches in the retina. (2) Exudative inflammation in the form of neuroretinitis, occurring with parenchymatous nephritis.

The so-called characteristic retinitis or neuroretinitis albuminurica is distinguished by whitish or yellowish-white patches of exudation, arranged in a more or less stellate manner around the macula lutea, and usually, though not always, accompanied by retinal hemorrhages, and by more or less œdematous swelling of the optic disk. These patches of exudation are mainly in the inner layers of the retina. They appear first in the region of the macula or between it and the optic disk. They tend to increase in number and size, and are apt to coalesce, concealing the retinal vessels in places. The ophthalmoscopic appearance of these patches changes but slowly, and often remains the same for weeks and months at a time, but there is a constant tendency to increase, and complete absorption and disappearance is almost never observed. They are probably due indirectly to the coexisting high arterial tension. The retinal hemorrhages are due to a weakening of the walls of the small vessels and to the increased intravascular tension. In granular degeneration of the kidneys there is a notable diminution in the size of the retinal arteries, and in these cases the pulse usually shows marked incompressibility.

The retinal hemorrhages are not characteristic. They may be few or many, depending upon the extent of the degeneration in the walls of the vessels. They are more apt to be linear than flame-shaped, and toward the periphery of the fundus are more circular or in patches. They may be found all over the fundus and may be entirely absorbed, but are prone to recur.

The vascular walls are thickened and appear as white streaks, which however are often concealed by the patches of exudation and the hemorrhages. These changes are noted especially in the small arteries and capillaries. They are found not only in the retina, but also in the chorioid, iris, and conjunctiva.

There is generally extensive œdema of the retina, which sometimes gives rise to folds, which may end in detachment of the retina, thus complicating the defective vision already existing.

The white patches in the retina consist of more or less extensive fatty degeneration of the retinal elements, accumulations of fatty granular cells, and hemorrhages in process of absorption.

The ophthalmoscopic changes show that the disease in the eye is primarily essentially a disease of the blood vessels. All the other lesions, hemorrhages, œdema, fatty degeneration, folds and detachment of the retina are secondary. These secondary changes are more marked in the retina than in the other ocular structures, because the retinal arteries are terminal arteries, and disturbances in the circulation here are not compensated as readily as in the chorioid or iris.

The disease is almost always bilateral, though it does not always begin simultaneously in the two eyes, nor is it equally developed in the two eyes. Unilateral retinitis albuminurica, though rare, is not extremely so. Cases have been reported by Cheatham, Yvert, Bull, and others. The impairment of vision varies greatly, and is often greatly disproportionate to the ophthalmoscopic picture. It is greater when the optic nerve is involved, and here often ends in atrophy of the optic nerve. Vision will often vary without corresponding ophthal-

moscopic change, but complete blindness is very rare.

*Retinitis albuminurica* occurs in all forms of nephritis, including the acute nephritis of scarlatina. It is met with in waxy kidneys, but only when this form of degeneration occurs in contracted kidneys. It must be regarded as one of the terminal symptoms of nephritis, as life is rarely prolonged more than a year, or at the most two years, after the recognition of the retinal lesion. Of one hundred and three cases occurring in my own practice, 75 per cent. died within the first year, and of these cases 62 per cent. died within six months. The prognosis seems to be more favorable for women than for men. Belt has collected 419 cases of retinitis albuminurica, of whom 65 per cent. died within one year, and 6 per cent. lived longer than two years. The statistics furnished by Hähnle, Rogers, and Trousseau all show practically the same proportion of early deaths.

The proportion of cases of nephritis in which retinitis albuminurica occurs varies, according to different authorities, between seven and thirty-three per cent., the average being about one in three and a half cases. It is most frequent in the granular kidney.

The *prognosis* is therefore unfavorable both as to vision and to life. The vascular changes, which are the root of the trouble, are general throughout the body. Exudative retinitis with hemorrhages must be regarded as more unfavorable than retinitis without hemorrhages. Temporary improvement frequently occurs, but complete recovery is only possible in the acute nephritis of scarlatina and in pregnancy, when premature labor has been induced. The retinal lesion is either the result of extensive disease of the blood-vessels existing in the various organs of the body, or it is the result of long existing renal disease. Hypertrophy of the left ventricle of the heart will of course favor the occurrence of hemorrhages, but it cannot now be regarded as a necessary link between diseases of the kidney and the retina.

The *retinitis albuminurica* of *pregnancy* may exist without any extensive organic disease of the kidneys. It has been observed as early as the third month, but it is more frequent at the seventh or eighth month, and more often in primiparæ.

As impairment of vision does not always occur early in the disease, regular and frequent ophthalmoscopic examinations should be made in patients during pregnancy whenever albuminuria exists. The main question to decide in these cases is as to the advisability or necessity of inducing premature labor. This should always be done when the retinitis occurs in the early stages of pregnancy. but it is not always advisable when it occurs during the last few weeks of pregnancy. In all cases occurring before the sixth month of pregnancy, labor should be induced and the patient delivered of the fœtus. In the later stages, the condition of the retinal vessels should decide the question of interference. If the vessels are approximately normal, retinitis during pregnancy is not a very grave lesion. If the central retinal artery and its major branches present the appearance of white cords, then the capillaries are presumably entirely obstructed, and if the condition is not relieved, the retina and optic nerve will become atrophied.

*Uræmic amblyopia* or *amaurosis* is one of the symptoms of general uræmic poisoning, and is more frequently met with in the nephritis of scarlatina and pregnancy than in the ordinary form of chronic nephritis, in which the proportion is only in about one per cent. of the cases. The disturbance of vision is always bilateral, develops rapidly, and generally passes into total blindness. Usually all ophthalmoscopic signs are negative even in the height of the seizure. The symptoms quickly disappear when the blood state is relieved by purgation or diaphoresis. The amblyopia is usually associated with headache, vomiting, stupor, and convulsions. The pupillary reaction to light is generally preserved, and unless there exists a previous retinitis albuminurica, there are no ophthalmoscopic changes. The coexistence of retinitis albuminurica is comparatively rare, and when present it is of course the prior condition. During the attack, whether convulsions are present or not, the pupils are usually dilated. The uræmic amblyopia is of course the result of acute autointoxication, from defective excretion of the poisonous products of malassimilation. In the uræmic amblyopia of pregnancy the actual retinitis may not be developed until parturition begins.

In the retinitis albuminurica of pregnancy, in some cases the inflammation of the optic nerve predominates over the retinal changes, so that it may appear to be the only ocular lesion. It resembles that form of neuritis met with in connection with intracranial disease, but careful examination will show signs of slight retinal degeneration.

The transient amaurosis sometimes observed in albuminuria is due to the vascular tension common to this disease.

In those cases of so-called physiological or transitory albuminuria occurring in active, healthy young men who are working under forced pressure, ophthalmoscopic examinations for retinal hemorrhages should be made frequently. When retinal hemorrhages occur in young persons without albuminuria, the patients should be kept under observation, the urine should be frequently examined, and the quantity passed noted. When these conditions are found the patients should be warned of their condition, so that they may be able to coöperate intelligently with their physician.

## EYE LESIONS IN HEART AND KIDNEY DISEASE.*

By FRANCIS KINNICUTT, M.D.,
NEW YORK.

It is with much justifiable diffidence that I venture as a general clinician to discuss the paper which has been read, a paper of great interest, both in its technical completeness and in its practical clinical character. I shall limit myself to a reference to that portion of the paper which treats of the symptoms and lesions occurring in the course of diseases of the kidneys.

Inasmuch as certain ocular symptoms occurring in diseases of the kidney are the result of a toxæmia *per se*, it is of interest to recall that opinions differ in regard to the nature of the toxæmia. It is held on the one hand that the toxæmia is due simply to the retention of excrementitious products in the blood, products of a *normal* metabolism, only toxic because they are retained; on the other hand, that the poison or poisons are the result of an *abnormal* metabolism, one of the functions of the kidneys being to control the metabolism of the tissues of the body. Experimental evidence would *seem* to show that when the kidney substance is greatly diminished in amount, the blood not only contains a great excess of urea, but the tissues, and especially the muscles, also contain large amounts of urea and other nitrogenous bodies of the creatin class, an

*In discussion of a paper on "Eye Lesions Occurring in Diseases of the Heart, Blood-Vessels, and Kidneys," read by Dr. C. S. Bull at a meeting of the New York Academy of Medicine, November 5, 1903.

amount which cannot be explained on the hypothesis of simple retention, but which strongly suggests an increased *production* of these products.

*Uræmic Amaurosis.*—The result of a toxæmia *per se*, this symptom is usually associated with characteristic symptoms of the uræmic state—headache, vomiting, stupor, convulsions, in varying arrangement. It is important, however, to bear in mind that an amaurosis may occur in renal disease in the absence of any of these symptoms. I occasionally have seen it develop in the acute nephritis of scarlatina without other evidence of uræmia. In these cases there has been nothing more than a marked but rather rapid diminution in the urinary secretion, which contained albumin, red and white blood cells and casts. The point of selection by the poison was evidently the central or peripheral parts of the visual tract.

The onset of the symptom is sudden. In some cases which have come under my observation the vision failed rapidly, in others a period of several hours elapsed before it was wholly lost. Although rapid recovery of vision with the relief of the uræmic state is the rule in uræmic amaurosis, further information on the after history of these cases as regards vision would be of interest.

*Cyclic or So-called Functional Albuminuria.*—In view of the varied opinions entertained in regard to the true character of this disturbance and of the findings by several ophthalmologists of ocular lesions in cases diagnosticated as functional, I would urge the importance of careful ophthalmoscopic examinations in such instances whenever possible.

The retinal changes which have been reported by trustworthy observers suggest the probability that some of these cases at least are dependent upon structural changes in the kidneys.

*Albuminuric Retinitis and Neuroretinitis.*—Undoubted cases of retinitis and neuroretinitis have been observed in some of the acute forms of nephritis, but it generally will be admitted that it is essentially a lesion of the chronic forms and especially of interstitial nephritis (contracted granular kidney). It equally will be admitted, I believe, that the period of the disease at which retinal changes *develop* is not easily determined. Dr. Bull's statistics indicate that the characteristic lesions are usually associated with advanced structural changes in the kidney.

Dr. Bull strongly insists upon the all-important point that the disease of the ocular tissues in albuminuric retinitis and neuroretinitis is essentially and primarily a disease of the blood vessels, and that the œdema, hemorrhages, exudations, etc., are secondary lesions. It is a well-recognized clinical fact that similar secondary lesions occur in arteriosclerosis without evidence of organic disease of the kidney.

Again, in a certain number of cases diagnosed as albuminuric retinitis, the structural renal changes are relatively slight and probably have little influence in producing the vascular changes and consequent ocular lesions. In other words, the retinal changes in these cases cannot properly be termed albuminuric; they are the expression of a general arterial disease. A recognition of these facts is of importance in prognosis.

General arterial degeneration—arteriosclerosis—even of an advanced grade, although a condition to be deplored, is not inconsistent with prolonged life and even with fair health.

Unfortunately many of the symptoms of chronic nephritis and general arterial degeneration are similar, being produced by the same causes, narrowed vessels and high arterial tension; but careful and continued studies of the urine and vessels often permit of a differential diagnosis.

In well-marked retinitis, associated with a positive clinical history of chronic nephritis and with *general* arterial disease, my experience corresponds with Dr. Bull's. As a rule a fatal issue of the disease may be expected within the limit of two years. It should be borne in mind, however, that the statistics on which such opinions are based are largely drawn from hospitals and dispensary services in patients for whom favoring conditions for combating the disease are lacking. In retinitis, associated with chronic nephritis but with an *absence of signs of general arterial disease*, and also in retinitis, associated with general arterial disease but without a positive clinical history of chronic nephritis, my belief is that a much less unfavorable prognosis as regards duration of life may be given.

From the cases of retinitis, associated with renal disease and arterial degeneration, which have come under my observation in private practice in the past eighteen months, I have selected three as illustrative ones, and I shall beg your indulgence for a brief report of their clinical histories.

Case I.—Mr. A., forty-eight years. Referred by Dr. Clement Cleveland, February, 1902. Excellent family history and exceptional health until 1895, when, to quote the patient's interesting observations on his own case: "While bicycling, suddenly a partial loss of vision. On looking in a mirror with his left eye closed everything was edged with red. The next morning there was a dark spot on the field of vision of his right eye. There was no pain or discomfort and no conjunctival injection. The dark area gradually increased in size till it spread beyond the center."

Uranalysis showed the presence of a small amount of albumin, a few red cells and a few hyaline casts. The specific gravity was below normal. An ophthalmoscopic examination, both by Dr. Knapp and Dr. Weeks of this city, showed a unilateral retinitis—right—with retinal hemorrhage. Again to quote the patient:

"The spot gradually decreased and disappeared except for a small place to the left of the center, which showed itself only by distorting any line seen on that part of the retina."

There were no further symptoms and excellent health was enjoyed until February, 1902, *seven* years later, when suddenly the patient again noticed a dark spot in the right eye, which increased gradually in size. An ophthalmoscopic examination by Dr. Weeks revealed a unilateral retinitis—right—with minute points of exudation and hemorrhage, and thickened vessel walls.

Physical examination showed an absence of cardiac hypertrophy, no appreciable thickening of vessel walls—temporal and radial—and normal blood-pressure. The urine contained a trace of albumin, and a few hyaline and granular casts. Its specific gravity was slightly below normal, and the daily secretion was above normal limits.

There were no other symptoms and the patient's apparent health was excellent.

The case must be regarded as one of probable albuminuric retinitis, occurring in the interstitial form of nephritis, and *disassociated with general arterial degeneration.* Points of much interest in the case are the unilateral character of the retinitis, the absence of signs of *general* arterial degeneration as indicated by the condition of the peripheral arteries and the absence of cardiac hypertrophy, and the excellent health enjoyed during a period of

eight years from the appearance of the first ocular changes.

In striking contrast to this case is

CASE II.—Mr. K., fifty-nine years. Referred by Dr. Thigpen of Montgomery, Ala, April, 1903.

Good health until the autumn of 1902. Then occurrence of digestive disturbances of a persistent character. A little later paroxysmal dyspnœa, gradual loss of weight and strength, and in April, 1903, sudden partial loss of vision. Ophthalmoscopic examination by Dr. Thigpen revealed a bilateral retinitis, and the urine was found to contain albumin. A personal physical examination three weeks later showed marked cardiac hypertrophy without valvular disease, a marked thickening of the peripheral vessels and a pulse of great tension; the sphygmomanometer indicated a blood-pressure of 270 mm. (Hg.). (Normal in adult male, 130-150). The urine was of low specific gravity and contained albumin, 2½ per cent. (Esbach), hyaline and granular casts. Ophthalmoscopic examination by Dr. Stedman Bull showed a bilateral neuroretinitis with exudation and hemorrhage. Death occurred six weeks later from uræmic toxæmia.

The case is an excellent example of albuminuric retinitis—probably the interstitial form of nephritis, with exacerbation—and *general* arterial disease.

CASE III presents the interesting clinical picture of a retinitis associated with chronic diabetes mellitus, chronic nephritis, and general arterial disease.

Mrs. H., sixty-four years. Referred by Dr. Stedman Bull, April, 1903. Mother died of diabetes, Good health until five years ago, when she developed a carbuncle on left leg. Urine had not been examined previously, but glucose was discovered at that time. Exact amount not stated, but patient was told it was considerable; no mention was made of presence of albumin or of kidney disease. Within a few months a rather sudden failure of vision occurred. No ophthalmoscopic examination was made. Sight gradually improved. Consulted Dr. Bull in February, 1903, suffering from another attack of failure of vision, who found a bilateral exudative retinitis with hemorrhage punctate and striated, and general œdema of the retina. The media were clear. Physical examination showed hypertrophy of the left ventricle (apex impulse 3½ inches from midsternal line; normal in adult female of average size, 2¾ to 3 inches), diffused thickening of moderate degree to feel of radials and temporals, marked increase of arterial tension, the sphygmomanometer registering 215 mm. (Hg.), moderate accentuation of aortic second sound, slight secondary anæmia.

*Uranalysis.*—A number of specimens examined, at intervals of a few days, showed an average specific gravity of 1012, a trace of albumin, a varying amount of glucose up to 4 per cent., and hyaline and granular casts.

The patient's health, as regards subjective symptoms, fair, and has continued so to present date, five years from the first noticeable symptom. My impression of the case, from the clinical history, is that the first failure of vision may have been due to arterial degeneration associated with diabetes, that the present retinitis is certainly partially albuminuric in character, that arterial degeneration is advancing rapidly in association with a nephritis of the interstitial form.

The present prognosis, as regards duration of life, in view of the association of chronic nephritis and general arterial degeneration with retinitis, should be regarded as very grave.

In conclusion I would urge the importance of a careful study of all cases of retinitis, belonging to the category referred to, from the point of view both of the ophthalmologist and general clinician, and especially for the determination, in so far as possible, of the presence and degree of general arterial disease. In this way, it seems to me, valuable assistance may be gained in the matter of prognosis.

---

## A REPORT OF THREE YEARS OF OPERATIVE WORK PER VAGINAM AT ST. JOSEPH'S HOSPITAL, YONKERS, N. Y.*

BY HENRY MOFFAT, M.D.,
ATTENDING SURGEON, ST. JOSEPH'S HOSPITAL, YONKERS, N. Y.

AFTER three years of operative work by the vaginal route it has seemed fitting to present a brief review of our results. This I do in all modesty with the encouragement and assistance of my colleagues at St. Joseph's Hospital, who have kindly put their cases at my disposal. It is my purpose to present a perfectly candid and unadorned statement, recording failures as well as successes. It is not my object to enter into an historical sketch of the growth of this branch of surgical work. The subject has been threshed out in discussions and medical journals for many years. The advocates of both the abdominal and vaginal routes have said about all that could be said about the method of their choice, but when the advocates of one route admit the benefit, in many cases, of the other method of procedure, it would seem the part of a wise surgeon to perfect himself in the technique of both. That the technique of vaginal work is difficult I admit, but that with ordinary care, attention, and perseverance a certain degree of proficiency can be attained, I think the appended summary of cases more than proves. For not one of us at St. Joseph's Hospital claims to be a specialist in this line of surgery. This is distinctly the work of men in general practice and of a more or less limited experience in general surgery. Three years ago, after some disheartening results of abdominal sections for pyosalpinx, it was my pleasure to witness Dr. J. Riddle Goffe do two vaginal operations by his method, *i.e.* through the anterior fornix. My preconceived idea, which I find many still hold, that vaginal work is "work in the dark," was immediately changed. By this method I never had a better or clearer view of the pelvic viscera. Inspired by his enthusiasm and by the results which I saw him attain, with so little disturbance to his patient, I determined to try the same method at my first opportunity. This occurred very soon after, and with Dr. Goffe's kind assistance I performed the first vaginal section by the anterior route at St. Joseph's Hospital on March 31, 1900. I will report this case somewhat in detail, as it is a good example of what can be done by this method:

Mrs. E. H., aged thirty-six years, widow, school teacher, admitted to St. Joseph's Hospital March 31, 1900. She had been suffering from chronic endometritis with profuse leucorrhœa and metrorrhagia for ten or twelve years. When I first saw her she was a confirmed invalid, confined to her bed a great part of the time. Examination showed chronic endometritis with marked retroversion of the uterus, and two small fibroids on the anterior wall near the fundus. The uterus not fixed by adhesion.

Operation, March 31, ether anæsthesia. After careful sterilization of the vagina and a preparatory curettage of the uterus, a slightly curved horizontal incision, two inches in length, was made in front of the cervix at the vaginal fold—with the finger

*Read at a meeting of the Section on Obstetrics and Gynecology of the New York Academy of Medicine, October 22, 1903.

the bladder and cellular tissues were dissected backward and upward, beginning at the sides, the finger being swept gradually toward the median line till finally only the uterovesical ligament remained adherent. This was carefully cut through with a knife with the edge held toward the uterus, the bladder being pushed up and out of the way. The peritoneum was then punctured with the finger and, two fingers being inserted, was torn laterally to the extent of the outer incision. To enlarge this opening a longitudinal incision was made in the median line in the anterior wall of the vagina as far forward as the urethra. The two free ends were grasped by artery clamps and, these being used to steady the flaps, the bladder was dissected away by lateral dissection with the handle of a scalpel. This gave a triangular opening 2x2½x2½ inches, through which the fundus uteri was readily delivered into the vagina by grasping the tube and broad ligament very near the uterus with the thumb and forefinger of the left hand. The two small fibroids were readily excised, and the peritoneal covering was stitched with a continuous catgut suture with little or no hemorrhage. The round ligaments were shortened in the following manner: the ligament was grasped as far from the uterus as possible with a long artery clamp and pulled down till a U-shaped loop was formed. Then a short needle, threaded with twisted silk, was passed through both parts of the ligament at the base of the U and firmly tied. The summit of the loop was then stitched to the fundus of the uterus. This completed, the ligament of the other side was similarly treated, and the uterus was returned to its normal position. The longitudinal incision was closed by a continuous suture of chromicized catgut—a firm vaginal packing of iodoform gauze was placed in position, and the patient was sent to her bed. She made an uneventful recovery and was discharged cured on May 9. A retroversion pessary was inserted to lift the uterus and take the strain off the ligaments. This she was directed to wear for three months. I have reported this case in full, as I said above, to give the technique which my colleagues and I have followed in all of our cases of anterior section. There have been a few slight variations from this as the requirements of the case demanded, but in every essential detail this method has been followed. For instance, in some cases it has not been found necessary to make the longitudinal incision, the fundus uteri being easily delivered through the horizontal incision; but when the uterus is large, or a large and cystic ovary is present, time is saved by the more ready access to the parts permitted by the larger opening. Through this opening the uterus is frequently so completely delivered into the vagina that the fundus presents at the ostium. When it has been found difficult to deliver the uterus with the fingers, I have, at times, used a blunt obstetrical hook with no apparent injury to the tissues. This should be handled with the greatest care and the point of the hook turned toward the median line after it has been passed behind the tube, so that traction is made upon the fundus uteri and not upon the tube, which might readily be broken. When an ovary or tube has been removed, and drainage is deemed necessary, a posterior incision is made through Douglas's pouch and gauze is inserted. The only danger of any moment to be avoided in this operation is that of wounding the bladder. This is not uncommon, and was my lot in my second case, but by dissecting carefully first at the side and then dividing the uterovesical ligament upon the finger, this accident is more readily avoided. It was neglect of this precaution that lead to my mishap. There has not been a death in any of our anterior operations, and in only one a serious infection. In this case, which I saw with Dr. Duffy, a very successful anterior section was done, and the round ligaments were shortened in the manner described. On the evening of the third day Dr. Duffy asked Dr. Hermance and me to see the case with him, as it was doing very badly. We found the woman in collapse with every evidence of a profound septic peritonitis. We advised an immediate posterior section to drain the pelvis. The woman was immediately taken to the operating room and Dr. Duffy made a rapid section through Douglas's pouch. As he pushed his fingers up through the recent adhesions at the back of the uterus, a seropurulent fluid poured out over his hand. Without any irrigation, gauze for drainage was pushed well up into the pelvic cavity, and the patient was returned to her bed. Her temperature in a few hours came down to normal and she made an uninterrupted recovery. I have always considered this a most instructive case, showing how readily septic peritonitis may at times be approached and treated through the vagina.

Before leaving this subject of the anterior incisions, I must refer to the result in two cases of complete procidentia uteri: one in which I operated and one in which I had the pleasure of assisting my colleague, Dr. Hermance. In both the procidentia was complete with retroversion. In both cases we amputated the cervix and shortened the round ligaments, and in my case repaired the perineum. In Dr. Hermance's case reparative work on the perineum was deferred to a subsequent date. After a period of two years in mine and one year in Dr. Hermance's case, the results are perfect. In my case the patient became pregnant just eighteen months after the operation, and after a perfectly normal and comfortable pregnancy was delivered naturally on the 5th of this month. The baby was a large, fully developed child, weighing about nine pounds. There was no distocia, the patient being in labor in all not more than four hours, which was less than the average duration of her previous labors. I have to record one failure in a case of retroversion: I performed the operation last November, and considered it at that time very successful, but in the following March I examined the patient and found the uterus sagging backward again. The ligaments were shortened in this case fully two and a half inches on both sides, and the summits of the loops were stitched together; but in spite of this there is retroversion at the present writing. The only explanation for the failure is that probably the uterosacral ligaments had been so stretched that, though relieved of their tension, they failed to regain their tone. It is only fair to state that when this patient returned for examination at the time mentioned, she was wearing a retroversion pessary which had been inserted by her family physician, but unfortunately was upside down.

The technique followed in nearly all of the posterior sections has been very simple and is as follows: After a cleansing of the vagina and a preliminary curettage, a horizontal incision one and a half to two inches in length is made, in the posterior fold through the mucous membrane, and the cellular tissue directly behind the uterus is dissected up with the finger until the peritoneum in Douglas's pouch is reached. This is either caught with clamps and cut through or punctured with the finger and torn to the extent of

the external incision. Then, if no adhesions are present and exploration of the pelvis only is desired, a Peon retractor and Pryor's trowel are pushed up behind the uterus and held apart. If in addition the patient's hips are elevated in the Trendelenburg position, a very clear view of the pelvis and its contents is presented. The retractors are taken out and one tube and ovary after the other are brought down into the vagina for inspection, where either excision or resection can be done as is deemed necessary. Pus tubes, pelvic abscesses, pelvic hæmatoceles, and tubal pregnancies have all been most readily approached in this manner. It is astonishing how readily the strongest adhesions can be broken up when the dissection starts from below. The fifty-four cases reported show only two deaths, and when it is noted that many of these were profoundly septic cases—single or double pyosalpinx or puerperal sepsis—I think we are justified in concluding that this method of procedure has earned its right to live. It is only fair to say that the patient in one of the fatal cases, was uræmic and nearly moribund when operated upon: the operation being done only as a last resort. There were two cases in which success was not attained by the posterior section and a later hysterectomy was necessary. These patients recovered. Two puerperal patients so treated died, the deaths being recorded under hysterectomy. In some cases a second operation was necessary to break up later pus formations, but all of these recovered. In puerperal sepsis it has been our practice when intrauterine irrigation has failed, after completely emptying the body of the uterus of all retained products of conception, to make the posterior incision for purposes of draining the infected secretions before any formation of pus could be detected either in the tubes or adjacent cellular tissue, and to pack the pelvis thoroughly after the manner suggested by Pryor with iodoform gauze. In several cases so treated the temperature immediately came down to normal and all the urgent symptoms abated. The following case is a good example of this treatment:

Mrs. H., aged twenty-nine, primipara; admitted May 5, 1902. Four days after her confinement she became profoundly infected, and when admitted had a temperature of 105.8° and a pulse of 140. Intrauterine douching had been kept up for two days prior to her admission without any benefit. She was immediately curetted and a posterior incision was made. Two Mikulicz pads were placed well up behind the uterus and loose gauze was packed between. Her temperature in twenty-four hours came down to normal and remained so for ten days, when the left tube became infected. A second operation was done and the tube and ovary were removed. The woman made a slow but steady recovery, and was delivered last August, just fourteen months after her discharge from the hospital, of her second baby without any outward symptoms. I have given this case simply as a picture of several such puerperal cases, which, at times seemed utterly hopeless, but finally ended in recovery. In two cases particularly desperate we were rash enough to do a hysterectomy with a fatal result in both.

The technique employed in the hysterectomies necessarily varied somewhat as the nature of the cases required. In the main, however, that laid down in the ordinary textbooks was followed pretty closely, except that in all the cases, with one exception, the angiotribe of Tuffier was used instead of clamps or ligatures. In no case was any hemorrhage recorded. At times it was found best to hemisect the uterus, after clamping off the uterine arteries, and then, the half uterus being turned into the vagina, the angiotribe was more easily applied to the ovarian artery from above. In one case of a large submucous fibroid on the posterior wall, the size of a grape fruit, I hemisected the anterior wall of the uterus and removed the tumor by morcellation, and then did a hysterectomy with the angiotribe. This patient was sent to her room in splendid condition and remained so until the next afternoon, when she rapidly developed symptoms of iodoform intoxication, which proved fatal in four days, in spite of all that could be done for her.

One unfortunate condition has been recorded in two or three of the cases, viz., a fecal fistula. This has been caused either by nipping a piece of intestine with the blade of the angiotribe or by violence in tearing up strong adhesions. With one exception these have rapidly healed spontaneously—so perfect is the drainage. Usually, after this operation with the angiotribe, there is absolutely no pain or discomfort, but whenever pain has been a marked symptom, I have found that the bowel has been injured. The dressing after hysterectomy is very simple—a large bunch of iodoform gauze is pushed well up through the vaginal opening and is left in for four or five days, being gradually withdrawn after soaking with a weak boric acid solution. In my opinion it is a mistake to try to make the vaginal opening smaller by suturing the edges of the anterior and posterior vaginal incisions together at the sides and placing only a strip of gauze to drain. In one case in which I tried this method a collection of pus formed in a pocket behind the posterior wall of the vagina. I was fortunate enough to discover this soon, and, after liberating it, I put in a large wad of packing, which filled out the pelvis and prevented any further pocketing, and the patient made a rapid recovery.

Finally, in puerperal cases, our experience would certainly seem to teach us that a hysterectomy is attended with the gravest danger, and that better results can be obtained by a posterior section with removal of infected tubes and the opening up and draining of local pus collections as they may appear. A patient adherence to this line of treatment has, in several cases, seemingly desperate, given us most satisfactory cures.

In summing up the subject, the following conclusions are fairly indicated, not only from my own personal experience, but from what I believe a candid study of the table of cases would teach.

1. The anterior vaginal route is most useful to reach and operate upon the round ligaments in cases of retroversion of the uterus or procidentia; also for removal of small fibroids, either subperitoneal or pediculated, or for conservative work on the ovaries and tubes, or for removal of these organs.

2. The posterior incision is most useful for drainage in cases of pyosalpinx, salpingitis, pelvic abscess, some cases of tubal pregnancy with hæmatocele and puerperal sepsis, either with or without involvement of the tubes; for oophorosalpingectomy, when the ovary is held backward and downward by old adhesions, and even in some cases of acute general septic peritonitis.

The more I see of this work the more am I impressed with the important truth that no pus tube should be attacked by any other route than by the vagina.

The following are the summaries of the tabulated record of vaginal operations performed in St. Joseph's Hospital during these three years. The members of the staff of the hospital whose cases, in addition to my own, are included in this table are Drs. E. M. Hermance, N. A. Warren, E. F. Duffy, G. M. Mooney, M. N. Foy, and O. L. Austin.

*Anterior Sections.*—Shortening the round liga-

ments for retroversion, 11; exploratory with breaking up of adhesions, 2; myomectomy, 2; resection of ovary, 1; single oophorectomy, 3; double oopherectomy, 2; total, 21 operations, with no deaths.

*Posterior Sections.*—Single oophorosalpingectomy, 21; double oophorosalpingectomy, 8; drainage for (*a*) pelvic abscess, 10; (*b*) puerperal sepsis, 6; (*c*) pelvic hæmotocele, 5; (*d*) salpingitis, 2; exploratory operations, 2; total, 54 operations, with 2 deaths, giving a mortality of 3.75 per cent.

*Hysterectomies.*—Performed for complete procidentia uteri, 7; puerperal sepsis, 3; double pyosalpinx, 3; uterine fibroma, 2; double pyosalpinx and uterine fibroma, 1; carcinoma uteri, 3; total, 19 cases, with 6 deaths, giving a mortality of 31.6 per cent. In all but one of the operations the angiotribe was used, in the one case clamps. The deaths were in cases of puerperal sepsis, 2; uterine fibroma, 2; carcinoma uteri, 1; double pyosalpinx, 1.

80 Ashburton Avenue

## INFLAMMATION OF THE BLADDER.

By HENRY G. SPOONER, M.D.,
NEW YORK.

Every case of inflammation of the bladder is caused by microorganisms, but these germs do not cause a cystitis in a normal bladder.

Any deviations from the normal arising in the general circulation of the blood, or in the urine, or from the spread of any pathological process, from the urethra, ureters or any neighboring organs into the bladder, or from any pathological condition arising primarily in the bladder causing a congestion in the histological layers of the bladder, predispose more or less to an inflammation of the bladder by causing a lessened resistance to the spread and growth of microorganisms that have entered the bladder through the general circulation, from the urethra or ureters, or in any other way. The conditions deviating from the normal that can favor the growth of bacteria after they have entered the cavity of the bladder are so numerous that it is beyond the conception of the human mind to grasp them or to make an adequate classification.

It has long been recognized that a congestion of the blood vessels in the wall of the bladder is one of the most important predisposing causes.

The study of comparative anatomy has shown that man assumed the upright position late in his development. While the assumption of this position has given us the superiority over the rest of the animal kingdom, yet it has given us one of the weakest bodies among the mammals, as the vascular system has not been able to adapt itself fully to this change assumed so late in our development.

The veins of the arms and legs have valves to prevent the hydrostatic pressure of the columns of venous blood from increasing too much by the force of gravity.

The large veins of the trunk have no valves. Thus in the portal system we have a direct column of blood, extending from the liver to the anus and bladder, exerting its hydrostatic pressure in these organs. This condition predisposes the bladder to chronic passive congestion.

The forces acting upon the organism, or any of its component parts, must come within the so-called physiological limits. Any excess of these limits is a cause of disease. Thus the bladder may be perfectly capable of coping with its ordinary conditions in youth, but in proportion as the regenerative force slackens with advancing years, the bladder becomes predisposed to a condition of chronic passive congestion, as in old age the system that undergoes the greatest change is the vascular system.

Cystitis, according to the course it runs, may be divided into (1) cystitis acuta and (2) cystitis chronica.

It may be divided according to the histological structures it involves into (1) cystitis mucosa (mucous membrane), (2) cystitis interstitialis or parenchymatosa (connective tissue and muscular layers). (3) Pericystitis (subserosa and muscularis).

It may be divided according to the more advanced changes of the component parts into (1) cystitis catarrhalis, (2) cystitis suppurativa, (3) cystitis crouposa, (4) cystitis diphtheritica, (5) cystitis gangrænosa.

Guyon has made a classification as follows: Cystitis caused by (1) gonorrhœa, (2) tuberculosis, (3) stones, (4) strictures, (5) prostates, (6) tumors of the bladder, (7) chemical irritation, (8) bacterial, and (9) cystitis in the female.

How unsatisfactory this classification is can be seen at a glance. The cystitis in the female, for example, may be any one of the other varieties.

Cystitis can never be said to be idiopathic, it is always secondary to some disease of the genito-urinary tract or to specific inflammations like tuberculosis. When cystitis is spoken of, the symptomatic cystitis acuta suppurativa, the most common form, should be considered.

It is caused (1) by the spread or advance of a pathological process from neighboring organs; (2) by pathological conditions arising in the bladder; (3) by modifications of the urine; (4) infectious diseases; (5) parasites; (6) poisons; (7) the uric-acid diathesis.

Guyon lays great stress on the constitution of the individual. Hereditary factors should also be carefully considered.

From 1875 to 1895 a mass of literature appeared to ascertain every microorganism that could cause a cystitis, and to show that microorganisms alone could cause this disease. On this theory the treatment was very simple, as all that was necessary to cure the patient was to kill the bacteria.

In 1860 a new era began. Pasteur, as a result of his experiments that have become classical, considered that an organic ferment was the cause of cystitis.

In 1874 Petersen[1] found that when the urethra of animals was bound for twenty hours, that the urine did not loose its acid reaction, and that pus was not formed. However, after injecting bacteria or foul blood into the bladder and tying the urethra off for a time, cystitis was caused. Injection of putrid blood into the bladder caused only a cystitis catarrhalis levis, but when the urethra was ligatured a cystitis gravis developed.

Dubelt,[2] in 1876, found that the injection of putrid blood into a normal bladder caused only a cystitis levis, but in the case of an injured bladder a cystitis gravis.

Droysen,[3] in 1883, found that stoppage of urine in a healthy bladder did not cause a cystitis.

In 1890 Krogius[4], by injecting his urobacillus liquefaciens septicus into the bladder, could only cause a cystitis when the urethra was tied for varying periods of time.

In 1892 Schnitzler,[5] from his experiments with injections of the proteus vulgaris Hauser and other bacteria collected from infected bladders, came to the conclusion that infection of the bladder did not always occur after a mechanical injury, or after a stoppage of urination, but under certain conditions quickness of increase in the bladder and the collection of toxic products could cause a cystitis, without any hindrance to urination.

Thus we see that the spread of bacteria into a healthy bladder exerts no lasting influence. That any injury to the bladder wall, or hindrance to urination, render a more favorable soil for the growth of bacteria in the bladder.

With the interest taken in the study of bacteriology in recent years, much attention has been given to find out the microorganisms found in infected bladders.

In 1886 Bumm,[6] in eight cases of puerperal cystitis, caused by catheterization, isolated a diplococcus which by its form and frequent grouping in the pus cells resembled the gonococcus. He injected cultures of these germs into the healthy bladders of dogs without producing any effects, but when the mucous membrane was first submitted to a chemical irritation, or when the urethra was tied, he produced a purulent cystitis. Bumm demonstrated the presence of this same diplococcus in the lochial discharges, and supposed that a sound had introduced it into the bladder.

Michaelis[7] confirmed the experiences of Bumm, in similar cases of cystitis, by finding the same microorganism. While these authors found diplococci in the cases of puerperal cystitis, the following investigations show that bacilli are found in the great majority of the other cases of cystitis:

In 1887 Clado[8] described a septic bacterium of the bladder.

In the same year Hallé[9] found a bacillus in pure culture in the blood and kidneys of a patient that died of cystitis.

In 1888 Albarran and Hallé,[10] in forty-seven out of fifty cases of purulent cystitis, found the same bacillus, always in enormous numbers; in fifteen cases it was found in pure culture. In the other cases it was associated with different species of cocci. They called it "bactérie pyogène." It is the same bacterium that Hallé and Clado have described. It is found nearly always in purulent urines with an acid reaction. These germs, when injected into the bladders of animals and the urethra tied, produced the same cystitis suppurativa.

Albarran,[11] in 1889, considered this bacillus as the most frequent cause of infection of the genitourinary tract, as it is always found, and often in large numbers. It was found by him in twenty-three out of twenty-five cases. Fifteen times in pure culture. In the eight other cases it was associated with other varieties of bacteria.

Tuffier and Albarran[12] found the same bacillus in four cases, three times in pure culture.

In all these works the "bactérie pyogène" were found to be the principal cause of the different local suppurating processes found in the different parts of the genitourinary tract. Albarran and Tuffier deserve the credit of being the first to describe and isolate these bacilli.

In 1891 Morelle[13] identified these bacilli with a species already known in the intestines, the Bacterium lactis aërogenes of Escherich, found in the fæces of nursing children.

In 1892 Krogius[14] regarded this bacterium as being identical to the ordinary bacteria of the intestine, but not to the bacterium lactis aërogenes, but to the Bacterium coli commune (Escherich). The cultures and experiments on animals showed a perfect concordance.

As a result of these investigations it can be seen that cystitis, like other suppurating processes of the genitourinary tract, is generally caused by the common bacterium coli commune found in the intestines. That these bacilli can exert no influence in the normal bladder, but when congestion, or stoppage of urine, occurs, the resistance of the bladder to infection is diminished, providing a favorable soil for the growth of these microorganisms. One of the chief difficulties in grasping this subject has been that each author has given a separate name to these germs.

The causes that weaken the bladder's normal resistance may be divided into (1) predisposing causes: (*a*) inherited, and (*b*) contracted; and (2) chance causes.

It is an interesting fact that foreign bodies and new growths of the bladder exert very little influence as long as they are not accompanied by a hindrance of urination. However, as soon as urine is passed with difficulty, or can not be passed at all, these conditions are of the greatest importance in starting up an inflammation of the bladder. In other words, as long as the decomposition of the urine in the bladder is not accompanied by congestion or circulatory disturbances of the wall of the bladder, no inflammation of the bladder occurs. The entrance of microorganisms can only exert a lasting influence when other lesions of the bladder have previously existed.

We shall now consider the diseases that tend to prevent the passage of urine.

It has long been recognized what an influence enlargement of the prostate gland has in causing inflammation of the bladder.

Strictures of the urethra, particularly those of the bulbo-membranous junction, gradually hinder the passage of urine. The residual urine increases, causing a congestion of the bladder, and then becomes alkaline and irritating from the ammonia set free from the decomposition of urea. The residual urine increases, exerting pressure on the pelves of the kidneys, causing pathological processes that are dangerous in the extreme.

Diseases of the central nervous system are very often accompanied with difficulty of urination, as Charcot has demonstrated. He has had occasion to follow some cases from the moment of strangury to the post-mortem examination. Acute and chronic gonorrhœal urethritis cause a swelling of the folds of mucous membrane of the urethra, that hinder the free passage of urine. They exert a direct or reflex irritation on the prostatic urethra, causing a more frequent desire to urinate, this, in turn, causing a frequent congestion in the blood-vessels of the bladder.

Laborers who work in laboratories where hydrochloric and other acids are manufactured are often afflicted in this way. The uric-acid diathesis works partly through changes in the kidneys, and partly through alterations in the other urinary organs.

How far chronic alcoholism exerts an effect we are not able to say. It probably acts by an irritating change of the urine, and through the process of fatty degeneration of the muscle layers of the bladder.

The toxic causes are chiefly cantharides and the terebinthinates.

*Prognosis.*—It can be readily understood how difficult it is to appreciate all the causes of the moment, from the clinical symptoms, physical examination, and even from an accurate bacteriological examination of the urine that should always be made. Therefore it becomes apparent how guarded the prognosis must be—the prognosis must be more unfavorable in proportion to the extent of the organic alterations that have taken place in the wall of the bladder, *e.g.* cystitis mucosa, cystitis interstitialis, and pericystitis. Even also on account of the more involved changes of the component parts, *e.g.* cystitis catarrhalis, suppurativa crouposa, diptheritica, and gangrænosa.

The general constitution must also be considered. The weaker the patient and the worse the diathesis so much more unfavorable is the prognosis.

We are only justified in prophesying a cure when we are in a position to quiet the predisposing causes.

*Pathology.*—Cases of acute or chronic cystitis are rarely seen at a post-mortem examination. We must, therefore, rely on our knowledge obtained from experiments performed on animals and from the cystoscopic study of the bladder on living subjects.

The cystoscopic study of the acute gonorrhœal form shows that the disease is not equally distributed, as it attacks the neck of the bladder and trigonum.

Fig. I.

The inflammatory area is intensely reddened.

The parallel branches of the blood vessels given off in the mucosa are dilated, making apparent all the finer branches that can not be seen in a state of health. The mucosa is swollen, the inflammatory area at the neck of the bladder can be seen shading off into the normal light orange pink mucous membrane of the bladder in figure 1.

The inflammatory area appears at the top, as the picture was taken with the No. 1 cystoscope of Nitze. In the case of cystoscopes, with the reflected light, the object is always reversed in the vertical diameter. In very acute cases extravasations of blood can be seen under the mucous membrane and exuding from it, adding to the congested appearance, as seen in figure 2.

Clumps of the degenerated epithelium that have been thrown off can occasionally be seen floating in the contents of the bladder.

When the inflammation subsides, the mucous membrane becomes paler, and the blood extravasations disappear one after the other, until we again get the appearance of the mucous membrane of the normal bladder, as shown in figure 3.

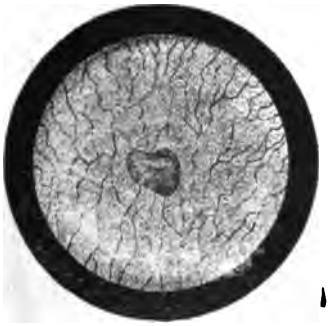

Fig. II.

The little round elevations seen in this picture are simply air bubbles that have been introduced by an imperfect syringe.

An experimental cystitis can be caused by cantharides. According to Guyon, three stages of the inflammation can be differentiated in animals so treated. (1) The blood vessels become congested and the epithelium is thickened. (2) The epithelium, having been invaded by pus corpuscles, is cast off. (3) The mucosa and muscularis are invaded by pus corpuscles and young round cells. A thickening of the mucosa and casting off of the epithelium, leads to the development of small abscesses that on emptying form surface ulcers, as seen in figure 4.

In a cystitis hæmorrhagica the bleeding occurs from the surface of a deeply congested and ecchymotic mucous membrane. Such hemorrhages must be differentiated from those that take their origin from a circumscribed area, due to trauma or tumors.

In catarrhus vesicæ the mucous membrane is hyperæmic, softened and swollen. The blood vessels are dilated, as shown in figure 5.

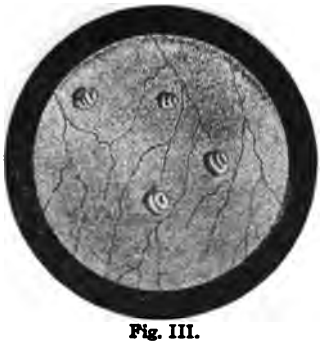

Fig. III.

The microscopical examination of the urine shows many red blood corpuscles, many pus corpuscles, clumps of epithelium, and numerous pus cocci and bacilli, according to the nature of the disease. The bacterium coli commune is nearly always found, often in pure culture.

In catarrhus vesicæ the mucosa shows only slight alterations. The congestion and casting off of the epithelium leave no important after-changes.

In cystitis suppurativa, of which the cystitis gonorrhoica, already described, is a type, the entire mucous membrane, or only a part of the same, is deeply reddened and thickened. In the intensely reddened areas, ecchymoses may be found. In cases that begin slowly and pursue a chronic course, we find the more important alterations on the base of the bladder. The epithelium is often thrown off, even to the deepest layers, and covered with strongly adherent pus.

When the inflammation has pursued a chronic course, the mucous membrane is decidedly hypertrophied in places. Small papillomata may be formed by the process of papillary proliferation. The small fibroma papillare (Virchow) so caused are the starting points of tumors of the bladder. Such conditions are seen often after the chronic gonorrhœal cystitis, often the muscular layers of the bladder hypertrophy, causing a trabeculated condition. In figure 6 is shown a trabeculated surface with a phosphatic concretion.

Fig. IV.

In cystitis parenchymatosa or interstitialis, we have an infiltration of pus into the submucosa and intermuscular connective tissue.

In pericystitis we have an infiltration of pus into

the subserous connective tissue. This may be the result of a spread of the cystitis parenchymatosa, or from the spread of an inflammation from neighboring organs. If an abscess is formed from a local accumulation of pus, it may empty into the bladder, rectum, vagina, or peritoneal cavity. Gravitating abscesses along the rectum are not uncommon.

Cystitis crouposa is a very rare disease, in which the wall of the bladder is covered over, with a more or less evenly measured fibrinous membrane, that can be removed without great substance losses.

Cystitis diphtheritica is caused most often from

Fig. V.

infection from open bladder wounds, or from the use of septic instruments, or from infection from the self-retaining catheter. Sometimes it occurs after severe infectious diseases, *e.g.* diphtheria, scarlet fever, and variola. It arises by contiguity from diphtheritis of the female genital organ. It has been seen in cases of paralysis of the bladder, or from infiltration of urine into a false passage made in the urethra. In all these cases the alkalinity of the urine favors a cystitis diphtheritica (Virchow). As a result of this inflammation, we have a large surface or several smaller areas of necrosis of the mucosa, leading to the formation of gangrenous grayish-black pseudomembranes, which are often encrusted with uric acid.

After these gangrenous eschars have been thrown off, either healing or a new advancing diphtheritic necrosis begins. This process may advance through ureters into the pelves of the kidneys. This process often leads to perforation of the bladder, with quick accompanying peritonitis, or to septic degeneration of the extraperitoneal connective tissue, when the point of discharge has not been at a place covered with peritoneum. In these cases we have an infiltration of the submucosa, forming abscesses in the wall of the bladder. When these interstitial

Fig. VI.

abscesses break into the bladder, pus is voided in large quantities from the urethra and healing begins.

Cystitis tuberculosa is of common occurrence, yet very little attention has been given to it in medical textbooks.

König considered that the half of all diseases whose chief symptom was the voiding of pus and mucus from the bladder was caused by tuberculosis. Rovsing considered that every cystitis with an acid urine was caused by tuberculosis. Melchior has, however, shown that the acid cystitis is only exceptionally tuberculosis.

Primary tuberculosis of the bladder is very rare. Most often tuberculosis of the bladder is noticed in connection with tuberculosis of the epididymis or of the prostate. In such cases it spreads very often into both kidneys. Tuberculosis of the bladder takes its origin very seldom from a descending course. Feleki has noticed cases of tuberculosis of the kidneys lasting for years without causing tuberculosis of the bladder. König, as proof of this fact, relates his experience that often after removal of a

Fig. VII.

tuberculous kidney which had caused vesical catarrh the latter quickly disappeared.

A secondary infection in the case of a tuberculous individual, through metastatic deposit of the tubercle bacilli is rare.

The disease advances by continuity. Cystitis gonorrhoica or other chance causes may make a more favorable soil for the tubercle bacilli that come from the kidneys. The pathological anatomy, as well as Rovsing's experiments on animals, vouch for the correctness of this statement. In these experiments tubercle bacilli were injected into the bladder, and the urethra tied off, but a tuberculous cystitis could not be caused in this way. However, when before these experiments the mucous membrane had been injured, or when a cystitis suppurativa had previously existed, cystitis tuberculosa could be caused in this way.

Tuberculosis of the bladder occurs more often in men than in women and children, and most often between the twentieth and fortieth years of life; still it is sometimes seen in young children and in old men. Birch-Herschfeld, out of 2,565 autopsies on women performed at the Dresden Hospital, found only four cases of tuberculosis of the bladder.

As the tuberculosis of the bladder, in most cases,

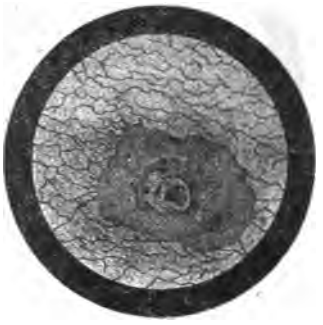

Fig. VIII.

is the result of a similar disease of the epididymis vas deferens, seminal vesicles, and prostate, as previously pointed out, spreading to the bladder, ureters, and kidneys, so it is easy to understand that the most important pathological changes in the overwhelming number of cases occur in the region of the ureteral openings and trigonum. This can be accurately seen in cases in which the cystoscope can be used.

We find numerous small, white-gray tubercles

which gradually increase in size, as shown in figure 7. These tubercles, through the process of cheesy degeneration, lead to ulcers. Surrounded by hyperæmic areas, as shown in figure 8. These ulcers increase in size, and as their walls coalesce, large tuberculous sores of the bladder arise that destroy a great part of the mucosa and submucosa. The symptoms are very much the same as in any other severe chronic inflammation of the bladder. In some cases the pain is very severe (cystitis dolorosa).

The prognosis is always unfavorable.

# OBSERVATIONS ON THE USE OF THE SAHLI TEST-MEAL.*

By EDWARD A. ARONSON, M.D.,
NEW YORK.

Early in 1902, Sahli[1] described a new method for the examination of the different functions of the stomach. In his opening remarks, he truly said that by means of the present methods of examination, we are unable to determine whether there is any disturbance, separately or together, of the motor secretory or absorptive functions of the stomach.

The quantity of a test-meal withdrawn after a stipulated time is not only dependent on the motility of the stomach, but also on the amount of secretion by the stomach; the percentage acidity is no direct indication of the secretion, but is also influenced by the motility.

The principle of the new Sahli method depended on the addition to a test-meal of some substance not absorbed by the stomach, which can be quantitatively calculated. After the withdrawal of the test-meal, it was possible to determine how much passed over into the intestine, how much remained in the stomach, and how much of the withdrawn meal consisted of gastric secretion. The important considerations, however, are that the entire test-meal should be homogeneous, that the substance which is to serve as the indicator should remain in complete admixture with the meal, and that, as v. Mering[2] has shown, the stomach absorbs no water. Fat was the substance selected by Sahli to serve as the indicator.

The idea of using fat for such a purpose did not originate with Sahli, but was first used by Matthieu;[3] v. Mering[2] also employed fat in the form of an egg-emulsion to determine the absorptive property of the stomach.

In order to undertsand the purposes of this paper, I will briefly describe the Sahli test-meal. Twenty-five grams of ordinary flour and fifteen grams of butter are placed into an iron or other suitable vessel over a flame and allowed to become a roast brown. To this are slowly added 350 c.c. of water, and the whole is constantly stirred; a little salt, sufficient for flavoring, is also added and the mixture allowed to boil for one or two minutes. After the stomach has been thoroughly washed, the patient is given 300 c.c. of this soup, and the reaining 50 c.c. are retained as a control.

After one hour the soup is withdrawn and the quantity noted. Three hundred c.c. of water are now introduced through the tube, and the stomach is gently massaged; within a few minutes, this diluted meal is then withdrawn and its quantity noted. The acidity of the soup first withdrawn and that of the diluted are determined and according to the formulæ of Matthieu,[4] which are as follows, we are enabled to calculate the amount which remained in the stomach:

a = the acidity of the undiluted soup.
b = the acidity of the diluted soup.
x = the quantity of soup remaining in the stomach:

Three hundred c.c. of water being used to dilute the soup remaining in the stomach after withdrawal of the first,

therefore $ax = b\,(x\ 300)$

$x(a-b) = 300b$

$$x = \frac{300b}{a-b}$$

The amount of fat in the control and in the first withdrawn soup is now determined. This was at first done by means of the Soxhlet method, but it was found to be too tedious and too inconvenient for clinical purposes. At the suggestion of Sahli, his assistant Seiler,[5] introduced the Gerber[6] butyrometric method, which is much more simple and rapid. Seiler made comparative estimates of both methods, and found the results to vary but very little.

Having found out the amount of fat in both the control and the withdrawn meal, Sahli uses this amount as an indicator and makes use of the foling terms and formulæ to reach results:

TO = amount of test soup withdrawn + the amount found to have remained in the stomach. The amount of fat in the soup which remained in the stomach, the "residue," gives an indication as to the amount of test soup retained—so that if in 300 c.c. test soup there is 4 per cent. fat—that is, 12 grams, and if, for example, we find that in TO there are 3 grams of fat, then we can conclude that $\frac{3}{12} \times 300$ c.c. = 75 c.c. remained behind of the amount of soup given to the patient. This remainder is designated by the term SU. Since TO includes soup + gastric secretion, then TO — SU = MA or gastric secretion. It must not be concluded that the amount MA includes all the gastric secretion, as some of the latter, together with some of the soup, certainly passed over into the duodenum.

*From the Internal Department of the Königin Augusta Hospital, Berlin, Germany. Prof. C. A. Ewald, Director.

To repeat, TO = amount withdrawn + residue
F = per cent. fat in the control or original soup.
f = per cent. fat in the soup withdrawn,

$$\frac{SU}{TO} = \frac{f}{F}$$

then

$$SU = \frac{f \cdot TO}{F}$$

therefore

The acidity of the pure gastric secretion is determined as follows:

a = acidity in per cent. of the withdrawn soup.
A = acidity in per cent. of the pure secretion.

$$\frac{a}{A} = \frac{Ma}{TO}$$

hence,

$$A = \frac{a \cdot TO}{Ma}$$

Seiler[5] found as standard figures in persons with normal digestion, the following which may be used for the sake of comparison:

| No. | Amt. introduced. | To | Su | Ma | Acidity of pure secretion. Per cent. HCl. |
|---|---|---|---|---|---|
| 1 | 300 | 124. | 72 | 52 | 3.5 |
| 2 | 300 | 158. | 83 | 75 | 4.4 |
| 3 | 300 | 57. | 30 | 27 | 3.5 |
| | Average | 113. | 62 | 51 | 3.6 |
| 4 | 250 | 113. | 44 | 69 | 3.2 |
| 5 | 250 | 108. | 56 | 52 | 4.2 |
| | Average | 110. | 50 | 60 | 3.7 |

From the above we notice that the amount of the HCl varies between 3.2 per cent. and 4.4 per cent. which figures lie intermediate between that found by Pawlow[7] in the normal gastric juice of dogs, to be 5 per cent. and by Schüle[8] and Troller[9] in the gastric juice of patients to be 1.8 per cent. — 3.6 per cent. If therefore in the application of the Sahli test-meal, the acidity per cent. of the pure secretion is found deviating one way or another from the above mentioned normal figures, we can diagnose a hyperacidity or a hypacidity.

The ratio between Ma and Su is taken as a secretion — quotient and normally is found to be 1; hence a material difference either to one side or the other leads to a diagnosis of hypersecretion or hyposecretion.

The motility quotient is found by using the formula, $\frac{300 - Su}{300}$; normally this quotient varies between $\frac{7}{8}$ and $\frac{9}{10}$ and anything above or below these figures determines a hypermotility or a hypomotility.

Acting on the suggestion given to me by Professor Ewald, I determined to apply the Sahli method to a series of cases taken from the rich material of the Polyclinic and some from the wards of the Königin Augusta Hospital, for the purpose of ascertaining its practical utility and whatever advantages it possessed.

Owing to the fact that the Gerber butyrometric method for the quantitative determination of fat requires a special centrifuge, which was not at my disposal, I employed another method, that of Schmid-Bondzynski,[10] for the same purpose. This is a much more delicate method than the Gerber but requires more time.

The following table as a result of my experience with this test is submitted with comparative diag-

| Series No. | Amt. Introduced. | Amt. Withdrawn. | "Residue." | To. | Su. | Ma. | Acidity of Pure Gastric Secretion | Diagnosis according to the Sahli Test-Meal. | | | Clinical Diagnosis. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | Per cent. | | | | |
| 1 | 300 | 110 | 87.09 | 197.09 | 99.445 | 97.645 | 29.5 | Hyperacidity | ..... | ..... | (Not mentioned.) |
| 2 | 300 | 35 | 150. | 185. | 163.78 | 22.22 | 9.5 | Hyperacidity | Hypersecretion | Hypomotility | (Not mentioned.) |
| 3 | 300 | 200 | 60. | 260. | 93.46 | 166.54 | 5.1 | Hyperacidity | Hyposecretion | Hypomotility | Ulcus ventriculi. Benign pyloric stenosis. Muscular hypertrophy. |
| 4 | 300 | 10 | 33.3 | 52.3 | 12.264 | 40.036 | 0.47 | Hypacidity | Hyposecretion | Hypermotility | Hypersecretion. Cholecystitis. Neurastheria. |
| 5 | 300 | 100 | 14.118 | 114.118 | 47.39 | 66.728 | 15.6 | Hyperacidity | Hyposecretion | ..... | Atonic ventriculi. Reu mobilis. |
| 6 | 300 | 90 | 66.6 | 156.6 | 68.31 | 88.29 | 14.2 | Hyperacidity | ..... | ..... | Chronic gastritis. Hypochlorhydria. Splanchnoptosis. |
| 7 | 300 | 65 | 150. | 215. | 105.23 | 109.77 | 2.1 | Hypacidity | ..... | Hypomotility | Splanchnoptosis. Hyperacidity. |
| 8 | 300 | 75 | 34.61 | 109.61 | 28.78 | 80.83 | 14.3 | Hyperacidity | Hyposecretion | ..... | Ulcus ventriculi. |
| 9 | 300 | 110 | 150. | 260. | 17.57 | 242.43 | 1.1 | Hypacidity | Hyposecretion | Hypermotility | Colitis. |
| 10 | 300 | 105 | 150. | 255. | 177.857 | 77.143 | 7.2 | Hyperacidity | Hypersecretion | Hypomotility | Carcinoma ventriculi. Lesser curvature (?) |
| 11 | 300 | 85 | 23.08 | 108.08 | 14.44 | 93.64 | 1.9 | Hypacidity | Hyposecretion | Hypermotility | Chronic gastritis. Splanchnoptosis. Pulmonary tuberculosis. |
| 12 | 300 | 16 | 100. | 116. | 13.84 | 102.16 | 0.8 | Hypacidity | Hyposecretion | Hypermotility | Cholecystitis. |
| 13 | 300 | 230 | 75. | 315. | 207.79 | 107.21 | 10.7 | Hyperacidity | Hypersecretion | Hypomotility | Hypersecretion. Hyperchlorhydria. Atonic ventriculi. |
| 14 | 300 | 160 | 93.75 | 253.75 | 46.48 | 207.27 | 7.1 | Hyperacidity | Hypersecretion | ..... | Albuminuria. Neurasthenia. |
| 15 | 300 | 105 | 150. | 255. | 168.21 | 86.79 | 3.2 | ..... | ..... | Hypomotility | Atrophic gastritis. |
| 16 | 300 | 285 | 23.07 | 308.07 | 252.41 | 55.66 | 3.7 | ..... | Hypersecretion | Hypomotility | Atonic ventriculi. |
| 17 | 300 | 135 | 50. | 185. | 54.95 | 130.05 | 7.3 | Hyperacidity | Hyposecretion | ..... | Atonic ventriculi. Achlorhydria. Cholecystitis. |
| 18 | 300 | 255 | 27.27 | 282.27 | 207.55 | 74.72 | 33.09 | Hyperacidity | Hypersecretion | Hypomotility | Catarrhal gastritis. |
| 19 | 300 | 90 | 150. | 240. | 130.60 | 109.34 | 2.4 | Hypacidity | ..... | Hypomotility | Catarrhal gastritis. Achlorhydria. |
| 20 | 300 | 220 | 58.53 | 278.53 | 194.44 | 83.09 | 47.7 | Hyperacidity | ..... | Hypomotility | Hypersecretion. |

noses, the one made according to the Sahli method, the other according to the clinical signs, together with the use of the Ewald-Boas test-meal.

In looking more closely over the table one is struck by the wide difference in many instances in the figures of the To and Acidity columns from the normal figures; again, in comparing the clinical diagnoses with those made according to the Sahli method, we notice the lack of agreement, especially in cases Nos. 4, 6, 17, and 19. All the patients were, of course, treated in accordance with the clinical diagnosis, and under such, improved or were entirely cured.

The very principle of the Sahli test-meal is open to criticism; it is not, as Sahli says, homogeneous for even on standing, within a very short time, there is a separation of the fat toward the surface and the thicker portion of the soup sinks to the bottom. Sahli also stated that this homogeniety was maintained by the constant churning through the peristaltic action of the stomach. This may also be objected to, for in every one of my cases, no patien was allowed to express the test-meal, but I aspirate. in each case, introducing the stomach tube at var-

ous levels and very often receiving the fluid at first, followed by the thicker portion, showing that the soup did not remain homogeneous within the stomach. This latter point was also observed by Koziczkowsky,[11] who says that the unequal distribution of fat within the stomach places the usefulness of the test in question. Bönniger,[14] in a criticism of the Sahli method, says that there is no equal distribution of the fat within the stomach, and on this ground alone depreciates the value of the test. Another cause for criticism is the fact that, owing to the presence in the stomach of a fat-splitting ferment, as was studied by Volhard,[15] the amount of fat remaining in the stomach after aspirating the test-meal is by the calculation entirely too small. Seiler,[5] however, in his work investigated this point, and states that the splitting up of the fat does not yet occur within the hour the test-meal remains in the stomach.

Owing to the fact that the soup as mentioned above, and as described by Sahli, was not homogeneous, I added mucilage of acacia in amounts of 30-50 c.c. to the soup, to make an emulsion and thus distribute the fat equally. I employed this emulsion in the second ten cases of my series. On aspirating, however, the homogenity was always disturbed in all cases in which mucus in any material amount was present. This corresponded with the findings of Zweig,[13] who says that the homogenity of the soup is disturbed in all cases of chronic gastritis with increased mucus and in cases of marked motor insufficiency.

Zweig made use of fifty-two cases, and found, as a rule, that the percentage acidity of free hydrochloric acid was considerably diminished as compared with Sahli's figures. In thirty-three cases he found varying combinations indicative of disturbances of the different functions of the stomach. No one case of nervous dyspepsia existed without showing a disturbance of function according to the Sahli test-meal. He further says that in cases of subacidity and possibly anacidity, the Sahli method is not commendable, as the irritation caused by the Ewald-Boas test-meal is more marked than when using the Sahli test-meal, and where free hydrochloric acid occurs with the former, it may be absent in the latter.

If we titrate the stomach contents in patients who have received an Ewald-Boas test-meal and also the Sahli meal, we will find that the figures resulting from each do not agree, but that the acidity after a Sahli meal is invariably less than after an Ewald-Boas meal. This is probably due to the fact, as above mentioned, that the roll of the Ewald-Boas meal stimulates the stomach glands to a greater degree than the bland soup of the Sahli meal and thus causes an increased secretion.

I made comparative examinations in many of my cases and found this always to hold true. I will mention only the few following cases:

| CASE NO. | EWALD-BOAS MEAL. | | SAHLI MEAL |
|---|---|---|---|
| 4 | Total acidity | 48 | 10 |
| | Free HCl | 28 | |
| 13 | Total acidity | 54 | 10 |
| | Free HCl | 34 | |
| 18 | Total acidity | 60 | 24 |
| | Free HCl | 42 | |
| 20 | Total Acidity | 82 | 49 |
| | Free HCl | 46 | |

Vannini[16] also made comparative examinations and was led to similar results.

Since its publication, the Sahli method has been criticised very freely by several observers, but no one, I believe, has called attention to the inconsistency in the determination of the acidity of the pure gastric juice. Sahli says that if on titrating the stomach contents we find a high percentage acidity then we should consider, in addition, the percentage acidity of free hydrochloric acid, as organic acids may be present in large amounts.

This test-meal serves well for the detection of lactic acid, as the soup contains none; in addition pepsin, rennet, starch digestion, etc., may be examined for in the same manner as when using other test-meals.

The application of the test-meal enables one to make a differential diagnosis between hyperacidity and hypersecretion which with the ordinary methods we are unable to do. Again, in the large number of different stomach conditions on a nervous basis which the internist sees, one can always find a disturbance of function when using the Sahli test-meal.

In the progress of clinical medicine we are continually looking for aids in order to perfect our diagnoses. Such aids, however, in order to be made use of by the general practitioner, must be practicable and not involve too much time in their employment. The Sahli test-meal certainly cannot be considered a practical aid, for no practitioner can allow himself the length of time necessary to carry out this test in the ordinary routine of practice, and therefore its use must remain limited to a hospital or sanatorium.

The Ewald-Boas test-meal has now been in use for many years, and has given satisfaction even to the specialist in gastric diseases, but this is no objection to the introduction of newer tests, which, in order to replace what we already have, must be simpler and give us at least as good results. A careful comparison of both tests fails to impress us with the results claimed by Sahli.

In summing up, I may mention:

1. When made up according to Sahli's description, the soup is not homogeneous.

2. The application of the test-meal to general practice is entirely impracticable.

3. The time consumed in determining results is incommensurable with the advantages derived from its use.

4. The lack of agreement in every case between the clinical diagnosis and the diagnosis according to the Sahli method.

5. The possible diagnosis by means of the test-meal, of function disturbance.

6. The diagnosis between the degree of acidity and amount of secretion.

Before concluding I wish to express my sincere thanks to Prof. C. A. Ewald and Dr. L. Kuttner for the material placed at my disposal and also for the great interest shown by them in carrying out the purposes of this paper.

## A TYPICAL CASE OF SPORADIC CRETINISM.

By FRANK P. NEWELL, M.D.,
BURLINGTON, WIS.

Reports of numerous cases of cretinism have been published in England, on the continent of Europe and in America (Osler collecting sixty cases in America up to 1897); but considering this case of special interest, I wish to report it to the medical profession.

The history of the case is as follows: L. R. is a boy of thirteen years, living in northern Wisconsin, and born of American parents. The family history is negative, with the exception that the

mother has a goiter. The father and three brothers are in good health and mentally bright. The symptoms first appeared at the age of nine months.

When I first saw the child, seven weeks ago, he was 36 inches high, and weighed 37 pounds. His head was large, 20½ inches in circumference; hair coarse and straight, but dark, and the forehead low. The eyes were small, half closed, with swollen lids, and far apart, the base of the nose being wide. The nose was pugged, the lips were thick, the mouth half open, and the tongue thick and protruding. The teeth numbered twenty, all very much decayed, and only two of his second teeth had appeared. The neck was short and thick, with small, fatty tumors in the supraclavicular region, just behind sternomastoid muscle. The abdomen was large, resembling that of rickets. There was a kyphosis of the spine. The hands and feet were short and stumpy. The whole body was covered with a scaly eczema. The perspiration was scanty. Temperature was 96° F., pulse 78. The appetite was poor and bowels constipated. The sexual organs were undeveloped. He was dull, taking no interest in his surroundings, seldom smiled, and never became excited. He could not talk and walked in a clumsy way.

The treatment was begun immediately, and consisted of the administration of the thyroid extract in 1 gr. doses twice daily for one week; then 1 gr. three times daily for a week; then 2 gr. twice daily, increasing to 2 gr. three times daily, which amount is the present dose.

The results have been marvelous. After six weeks of treatment the facial expression changed entirely; the thickness almost entirely disappeared from the lips, tongue, neck, feet, and hands. The large abdomen was very much reduced. The eczema disappeared. Temperature rose to normal, and perspiration was increased. The bowels moved regularly. He became more active, took more interest in things, and tried to walk. He grew one inch.

The interesting features of this case are: (1) That the patient could have reached his present age without his case receiving proper diagnosis and treatment; (2) that the patient was born in the United States of American parents, and (3) the prompt response to the treatment in view of the advanced age of the child.

---

**A Rational, Efficient, and Rapid Remedy for Gonorrhœa.**—W. H. Whitehead denies the truth of the theory that the gonococci invade the subepithelial spaces. It is rather the sulci and crypts in the urethral mucosa and their associated ducts that are the receptacle of the virus and that defy cleansing by any mere irrigation. He finds that the plugs blocking up these structures are best removed by a process of digestion. For this purpose he has devised a salve, the composition of which is as follows: Yellow oxide of mercury, gr. xx; oleic acid, ℥j; oxide of silver, ℥ij; powdered scale pepsin, powdered caroid, ää ℥iv; albolene, lanolin, water, ää ℥ij. He thus describes the treatment of a supposed case: A young man comes to the office with a plain case of gonorrhœa; was exposed five days ago; first noticed a little sticking of the mouth yesterday, drop of matter this morning; now has a drop, and signs on the clothing; has used no injection. Have the patient urinate, and instil one-half drachm of salve down the urethra two inches, put a bat of absorbent cotton over the penis to catch the salve that comes back, tie it on loosely, instruct the patient to keep the dressing on until he is compelled to urinate, and to come back twice daily for the insertion of the salve, morning and evening. Give internally this compound: sandal oil, ℥vj; powdered cubebs; benzoic acid, ää ℥j; powdered pepsin, ℥iv. M. ft. mass. Divide into 30 equal parts; put in cachets or cold wafers. Sig.: One before meals, and one at late bedtime. He finds that the salve is painless, the discharge is arrested by a two or three days' use of it, and radical cures are obtained by a dozen applications—six days' treatment. When all discharge has ceased for forty-eight hours and the first urine is clear, he suspends the local treatment, but continues the internal, or urine sterilizing treatment, for a week or ten days longer. If the discharge returns, he uses the salve again for one dozen instillations, by which time the discharge will have again disappeared entirely. He always continues the internal treatment during the entire course of the disease, does not irrigate, and does not let the patient use any injection.—*Therapeutic Gazette.*

## WOMEN IN MEDICINE.

To-day, in America and England, as in most of the other chief civilized countries of the world, there is no law prohibiting women from practising medicine and surgery. In the United States women as physicians and surgeons are making great headway, and there are undoubtedly more female doctors in this country than in any one country of Europe. It is somewhat curious, too, that Russia, which is the most backward of the nations in progressive movements, should contain a very large number of female medical practitioners, while Great Britain—which is generally regarded as the land in which the most enlightened views take their rise and flourish—does not take kindly to the woman doctor.

The *Nineteenth Century*, November, contains an article dealing with the medical woman question in Great Britain, written by a woman. The writer, after remarking that there can be but two opinions as to nursing being an appropriate calling for women, expresses surprise that when it comes to the profession of medicine, which is but a higher, more theoretical and learned development of the same science of medical nursing, she is still, in spite of plenty of testimony to her efficiency, looked upon dubiously, even as medical attendant by those of her own sex.

Women have practised medicine and surgery from time immemorial, and, according to history, as far back as the times of the early Greeks, met with opposition, but from men and not from women. To-day, in England, it is the women themselves who refuse to countenance their sisters as medical practitioners.

Concerning the origin and development of the woman doctor in Great Britain, it is related that the London School of Medicine for Women was opened in 1874; that three others have been inaugurated in the metropolis since then; that there are now six schools in England where they can study with men, and, though Oxford and Cambridge are closed to them, there are six universities in which they can obtain medical degrees and diplomas on equal terms with men.

It would seem that for a period of almost thirty years, women in Great Britain have had ample opportunity for study and hospital practice, and the results, in numbers taken from the last census, are that there were then 212 fully qualified medical women registered in the country—including Ireland and Scotland, 249. The New Hospital for Women, founded by a woman, has a staff entirely composed of females. The Royal Free Hospital has women house surgeons and physicians as well as men acting in the same rôles. Several poor-law infirmaries and county asylums employ medical women in their female wards. There is, however, but one female medical officer for vaccination and one lady bacteriologist.

Women, too have achieved their fair share of distinction in examinations in England, and have proved that at least they are by no means deficient in brain-power and in perseverance. Among those who have taken degrees from the University of London, seven have won the gold medals offered by that institution. In 1892 a lady took first class honors; the same lady, in 1893, qualified for gold medal in surgery, and in 1896 won the additional and unique honor of taking the degree 'M S." London.

The writer endeavors to explain why it is that there exists a prejudice in Great Britain against women as physicians and surgeons, a feeling which is especially strong among members of their own sex. It is pointed out in the article that the existence of this sentiment among women against the employment of lady doctors, is in many instances to their own disadvantage. "There are," continues the writer, "many thousands of women who would rather suffer for years than describe their symptoms to a man, who neglect their health because they have a repugnance to consulting a doctor, until their ailments, slight at first, through neglect have become incurable. Many long illnesses, painful operations, and supervening deaths might probably have been avoided in the past, if these women had either less modesty about consulting a medical man, or retaining that old-fashioned characteristic, enough confidence and faith in their own sex to consult a qualified woman in the capacity of a doctor."

Lastly, the suggestion is thrown out, that in every township of importance in Great Britain, a qualified medical woman should be appointed officer of health, by such means, it is thought, women in general would be induced to place more confidence in doctors of their own sex, and would make use of them, the result being that the nervous diseases of women so prevalent to-day, if treated by medical women, would greatly decrease.

Women in the United States practising as physicians or surgeons are in a far better position than their British sister practitioners. There is little or no prejudice against them, but, like other women workers, they must stand or fall upon their own merits. Some of them are prosperous members of the community. In the *New York Tribune*, November 22, is an article treating of the Woman's Medical College of Pennsylvania. In reference to the question of what becomes of its graduates, an inquiry was instituted, and an effort made to trace the careers of 244 of these. Seventy-six women stated the monetary value of their practice in a year. Twenty-four made $1,000 a year or more, but less than $2,000; twenty as much as $2,000, and less than $3,000; ten as much as $3,000 and less than $4,000; five as much as $4,000 and less than $5,000; three as much as $5,000 and less than $15,000; four reported sums varying from $15,000 to $20,000 a year. Ten reported less than $1,000 a year. The average income was found to be $2,907.30.

Perhaps, the main reason why medical women do not prosper in Great Britain as in other countries,

is the innate conservatism of the British people, and particularly of its women. Unlike the members of the female sex in the United States, they have not yet learned to be independent and to make their own way in the world, but still retain old-fashioned notions as to the duties which fall within the province of a woman. Undoubtedly, there is a large field everywhere for women of the medical profession, and it is just as certain that they are here to stay.

## SPOTTED FEVER OF THE ROCKY MOUNTAINS.

In the spring of 1902 Dr. A. F. Longeway, Secretary of the Montana State Board of Health, engaged the services of Drs. L. B. Wilson and W. M. Chowning of the University of Minnesota to investigate the "spotted fever" then prevailing in the Bitter Root Valley. Surgeon-General Wyman of the Marine Hospital Service detailed Surgeon J. O. Cobb to also investigate the disease, and his report was published in the Public Health Reports, Volume 17, No. 33, August 15, 1902. The report of Drs. Wilson and Chowning and that of Surgeon Cobb were commented upon editorially in the MEDICAL RECORD, October 4, 1902. On April 22, of this year, Dr. John F. Anderson of the Hygienic Laboratory, U. S. Public Health and Marine Hospital Service, according to instructions, proceeded to Montana to make further investigations, the results of which he has embodied in bulletin No. 14. In the first instance the writer suggests as the name for the disease now known as the "spotted fever" of the Rocky Mountains, that of "Tick Fever," as there are already two maladies sometimes called "spotted fever."

The disease has been known in the valley of the Bitter Root River in western Montana for about twenty years. It has also been known clinically in Idaho for many years, while it prevails in northern Nevada and is met with in Wyoming and Oregon. The affection is present only in the spring and early summer. The parasite which is presumably the cause of the disease was discovered by Drs. Wilson and Chowning, and was described by them as an ovoid intracorpuscular body showing amœboid movements. Dr. Anderson states that this parasite apparently lies between the parasite of malaria and that of Texas cattle fever, and from the constancy of these bodies in the blood of persons suffering with "spotted fever," from their persistence for some time in the blood of these persons after recovery, and from their absence from the blood of persons suffering with other diseases and of healthy persons, concludes that it is very probable they are the cause of the disease, and that one more has been added to the rapidly growing list of diseases of man due to animal parasites. The mode of infection of the disease is by the process of elimination, supposed to be by means of ticks. These are active when the disease prevails and are absent when the disease has died out. Mosquitos do not appear in the Bitter Root Valley until after the first cases of fever develop, and remain some time after the last cases appear. Bedbugs and other house insects, the writer thinks, are well excluded, by the fact that there has never been known an instance in which two cases have occurred the same year in the same house. Other contributory evidence pointing to the tick as the means of transmitting the disease is forthcoming. Like the mosquito in malaria and in yellow fever, the writer thinks that the tick plays the part of intermediary host in "spotted fever." Nevertheless, although all the known facts favor the belief that the tick conveys the disease, the question cannot be definitely decided until carefully controlled experiments have been made on non-immune persons. The incubation of spotted fever is from three to ten days, usually about seven. Little or no fever in the morning with a slight rise in the afternoon, until the chill comes on. Then the rise is abrupt, and henceforward the temperature gradually rises in the evening, with a slight morning remission. The maximum is usually reached on the eighth to the twelfth day; then, in a favorable case, gradually falls, becoming normal about the fourteenth day, generally going to subnormal for a few days. In fatal cases the fever remains high, from 104° to 105° or 106°, and the morning remissions are very slight or not present. The pulse runs very high—out of all proportion to the temperature—usually from 110 to 140—a pulse of 120 not being unusual with a temperature of 102°. The eruption appears, as a rule, on the third day, first on the wrist and ankles, then, on arms, legs, forehead, back, chest, and, last and least, on the abdomen. The spots when they appear are of a bright-red color, macular at all times, from a pin-point to a split pea in size. In severe cases they soon become darker and in some cases are almost purple. From about the sixth to the tenth day of the disease they are distinctly petechial in character. In favorable cases, on or about the fourteenth day they begin to lose their petechial character, and as the fever declines the eruption begins to fade. When convalescence is well advanced desquamation commences and extends over the entire body. Gangrene of the finger and toes, and still more frequently of the skin of the scrotum and penis may occur in very severe cases, while the skin is always jaundiced to a greater or less degree. The digestive system is greatly disordered, and constipation is present throughout the course of the attack. The nervous system does not appear to be severely affected, but there is a great deal of pain in the head, and back, and muscular soreness even in mild cases, lasting until recovery. Dr. Anderson was greatly struck by the close resemblance between spotted fever and typhus fever, but while typhus fever is intensely contagious spotted is exactly the reverse.

Quinine seems to act as a specific in the treatment of spotted fever and should always be used. Other remedies, however, are valuable as adjuvants. The drinking of water in large quantities is recommended in order to flush out the kidneys.

The writer thinks that the disease, considered from a public-health standpoint, is of far greater importance than it was formerly thought to be, for the reason that it is spread over a comparatively wide area. Of course if ticks are really the cause of the disease, their destruction will put an end to the malady. Dr. Anderson points out hat, owing to the size and nature of the region in which ticks abound, this would be an almost impossible task. He advises, when conditions will permit, burning the undergrowth and stubble as an effective method for the destruction of ticks.

## TREATMENT OF ACUTE NEPHRITIS.

No disease affecting the inhabitants of the civilized world, holds a more prominent place than nephritis in its different forms. The treatment, too, of this complaint taxes the physician's skill to the utmost. This is notoriously the case with acute nephritis, for the reason that here drugs are of little use.

Dr. Thomas J. Horder, writing in the *Practitioner*, November, describes the treatment of nephritis generally, and especially that of the acute stage. He points out that next to disorders of the digestive tract diseases of the kidneys are more than all others directly influenced by dietetic considerations, and is of the opinion that it is along the lines of metabolism that any advance in therapeutic knowledge can be expected. Dr. Horder is a follower of von Noorden, and believes with him that the best method to treat nephritis successfully is to study the elimination of the food principles themselves. Von Noorden, in his work "Disorders of Metabolism," advises the treatment of acute nephritis by paying strict attention to diet. The author classes the following amongst the substances excreted with difficulty by a person suffering from acute nephritis, urea, creatinin, pigments, hippuric acid, phosphates, inorganic sulphates. The substances well excreted are: uric acid, xanthin bases, aromatic substances, ammonia, amido-acids, chlorides, and carbonates. As regards water, the important observation is made that in the early stage of acute nephritis water is eliminated with difficulty; later on, this difficulty passes away. The dietary recommended in acute nephritis may be set out in the following scheme: (1) To be avoided (*a*) Because of creatinin produced: meat-extracts, meat-broths, eggs. (*b*) Because of pigments produced: foods containing hæmoglobin. (*c*) Because of hippuric acid produced: green vegetables. (2) To be given sparingly (*a*) Because of urea and sulphates produced: milk. (*b*) Because of irritant effect during excretion: water. (*c*) To be given with impunity in all but severe cases, because no injurious end products are produced: cream, butter, white vegetable soups, puddings made from oatmeal, flour or maize, white bread. To neutralize the bad effects of phosphates in milk, a little calcium carbonate is added; this enables the phosphates to be got rid of in the fæces. Von Noorden does not believe in an exclusive milk diet for all cases of acute nephritis, nor does he advise the procedure usually followed of giving an unlimited supply of fluids. For severe cases in which there is partial or complete suppression of urine, increasing œdema, and threatened uræmia the author allows only a pint of milk a day, and avoids other fluids. Thirst is relieved by ice or very small quantities of water, a little alcohol is allowed. Free diaphoresis is encouraged. After four or five days, or in cases less severe, such as are common during or after acute infectious diseases, milk up to two pints and a half is allowed with calcium phosphate added, and half to three-quarters of a pint of sweetened cream, previously sterilized. If more food is required no more milk is given but articles are added as in three above. Fluids are still restricted so long as there is oliguria and œdema, and diaphoresis is favored; but if the excretion of water is good throughout, or has returned after being deficient, fluids should be given freely. If the œdema is passing off, diaphoresis is unnecessary.

The convalescent stage demands more food and a more varied dietary. White bread, legumes, cream-cheese, a little egg or meat may be added, taking care to keep the total amount of proteid below 100 grams per diem. At this stage fluid will be well borne and does much good. If œdema reappears the skin must be stimulated or a dry climate chosen for the patient. In all stages diuretic drugs, whether acting upon the heart or directly upon the kidneys, are of no use.

Dr. Horder states that, according to his views, von Noorden is the most eminent authority upon kidney disorders now living, and he agrees, with the German writer in all that he says regarding the treatment of acute nephritis. Few will be found to dispute the assertion that drugs exert little or no beneficial influence on the course of acute nephritis, and the majority of physicians will confirm the statement that in this condition a suitable diet is the first consideration.

---

## GASTROPHILUS EPILEPSALIS LARVÆ IN THE SKIN OF AN INFANT.

The *St. Paul Medical Journal*, October, 1903, contains an account, by Dr. Burnside Foster, of the appearance of the above larvæ in the skin of an infant. The case was that of a female infant three weeks old, born prematurely and bottle-fed from birth. Its nurse was the first to notice a papular and pustular eruption of the neck beneath the jaw, consisting of not more than eight or ten lesions and one at the back of the neck. There was also noticed a pustule on the palm of the hand and one between the great and second toes of the right foot. Soon after attention had been called to this eruption, what appeared to be a small living worm, which had evidently come from the pustule, was found between the toes. Later a similar worm came from the palm of the hand and one from the pustule at the back of the neck.

The "worms," of which three specimens were obtained, were about one-fifth of an inch in length and evidently the larvæ of some species of fly. The specimens were sent to F. L. Washburn, State Entomologist, for identification, and by him forwarded to D. W. Coquillet, a specialist in diptera in the Department of Entomology at Washington, who identified them as Gastrophilus epilepsalis, a species somewhat closely allied to Gastrophilus equi, or bot-fly.

F. L. Washburn has also written an account, published in the *St. Paul Medical Journal*, of the little that is known of the history of the parasite, which is as follows:

"The genus belongs to the family of flies known as Œstridæ, types of which are found in the bot-fly of the horse, and in the so-called ox warble, which renders the backs of cattle sore and seriously impairs the value of the hides. Both of these flies lay their eggs on the hairs, which eggs later are licked off. In November, 1899, at the meeting of the Illinois Medical Association at Chester, Dr. H. C. Adderley reported a case under his charge of a boy ten years old, who had been subject to markedly characteristic epileptic spasms for four years, sometimes having twenty spasms in twenty-four hours. The general condition of the bowels was constipated. Upon the use of a cathartic, he noticed hundreds of maggots in the excreta. No one recognized these parasites, and French named them Gastrophilus epilepsalis.

He claims this case has all the appearance of being genuine epilepsy, the boy having globus hystericus with the spasms, and the other usual symptoms accompanied the attacks, including mental aberration."

Washburn thinks, from the language used by French, that the latter was of the opinion that the larvæ gave rise to other larvæ, and that when this occurred spasms would take place. Washburn, however, points out that with a few rare and well identified exceptions, reproduction in insects is confined to the adult or perfect form, hence the seeming absurdity of French's statement.

When the specimens of maggots were sent by Dr. Foster to F. L. Washburn they were at first thought to be Lucilia, but, as said before, D. W. Coquillet pronounced them Gastrophilus epilepsalis: "In other words, he says these subcutaneous maggots are the same as French's type, which was an intestinal parasite. Another specialist in diptera thinks that the parasites may be Lucilia after all.

Since the above was published in the *St. Paul Medical Journal*, Washburn has found an article, by Dr. Fred. Humbert, in Vol. V of the "Proceedings of the U. S. Natural History Museum, 1882," describing a case of maggots infesting man apparently similar to that of Dr. Foster. These maggots were identified by the late Dr. Riley, who was then U. S. Entomologist, as the larvæ of Lucilia macellaria. The larva of this fly being known as the screw-worm. Dr. Riley's identification tends to confirm Washburn in his views that the maggots sent him by Dr. Foster were Lucilia.

The case described in the *St. Paul Medical Journal* is interesting, both on account of its rarity, and owing to the difficulty in identifying the species of fly concerned. It would seem that Washburn is probably right when he suggests that the species is wrongly named, and that it has no connection whatever with epilepsy. At any rate, it is quite certain that there is much yet to learn with regard to its identification and life history.

### Insanitary Restaurant Kitchens.

Reference is made by the Medical Officer of Health for the City of London in his report for the past five weeks, published October 17, to the inspection of kitchens of restaurants. A portion of this report is contained in the *Sanitary Record* November 5, sixty-four of such kitchens were inspected for the first time, and many grave sanitary defects were discovered. Several of the kitchens were stated to be in a very dirty condition, the lighting and ventilation being bad, the floors defective, the cisterns uncleansed, and the sinks, ovens, and cooking utensils very much below the standard called for.

"As this inspection progresses," adds Dr. Collingridge, "I am led to more and more appreciate the great advantages accruing therefrom to the health of the customers using these restaurants, and still more to the workers who are compelled to spend their time underground in badly lighted, unventilated, and insanitary kitchens."

Full details are given in the report of the campaign directed against the sale of contaminated shell fish, and of ice-creams made on insanitary premises. With regard to ice-creams it is stated that: "In cases in which the manufacture of the article is carried on outside the city the Medical Officer of Health of the district in which the ice-cream is made is advised of the name and address of the manufacturer, and is asked for information as to the sanitary condition of the manufactory. In those instances in which unfavorable replies are received, steps are at once taken to prevent ice-creams manufactured at these places from being sold until the occupiers have complied with the requirements of the Medical Officer of Health of the district, and an intimation has been received to that effect."

There are doubtless insanitary kitchens in connection with many restaurants in New York, where these places of *public* entertainment are proportionately more common than in London. As to ice-cream, the manufacture and consumption of this delicacy is much larger than in the British capital. That food cooked in dirty kitchens is not conducive to good health, needs no emphasizing. Ice-cream manufactured under insanitary conditions cannot but be productive of a large number of cases of gastric disorder, and on occasion of serious sickness. The matter of both restaurant kitchens and of ice-cream manufacture is worthy of investigatin in New York.

### Tuberculosis among Indians.

The *New York Evening Post*, November 21, publishes a letter on this subject from D. A. Sanford, Bridgeport, Okla.

The writer had recently received a letter from the Rev. H. J. Kilemer, missicnary to the Cheyenne Indians, at Hammon, Okla., in which he said about tuberculosis: "I believe over 50 per cent. of the deaths occur from that cause. . . . An educated Cheyenne Indian told me: "In old days, the Cheyennes and Arapahoes were healthy and strong, with but few deaths. Many were killed in fights with white people, or with other Indians. They went barefooted over ice and snow, and through water. Now many have consumption. They catch the disease one from another." The Hon. W. J. McConnell, ex-governor of Idaho, wrote to the same effect and declared that Indian children were taken from their homes forcibly, and placed in poorly ventilated dormitories with tuberculosis patients. Mr. McConnell closed a four-year term as United States Indian inspector last July, and said he knew whereof he wrote.

Mr. Sanford enters a strong plea for just and humane treatment of the Indians, and asserts that if white persons were compelled to live under the conditions which are forced upon the Indian children, people would be aroused and demand a remedy. Races like Indians, who for generations have been accustomed to live a free healthy life in the open air, are peculiarly susceptible to tuberculosis when cooped up in a house. Contagious diseases of any kind will spread with amazing rapidity among such people, as it is virgin soil in which to take root. For this reason consumption —although contagious only to a slight extent— will quickly spread among Indians when they are brought into direct contact with those suffering from the disease. If the facts are as narrated by the correspondents of Mr. Sanford, steps should be promptly taken by the national authorities to safeguard the health of Indian children, and to permit them to live under proper sanitary conditions.

### Sanatoria for Consumption.

The opening of the King's Sanatorium for Consumptives, on November 5, has provided the opportunity to Dr. T. Glover Lyon to air his views with regard to sanatoria. His opinions, as expressed in a communication to the *London Times*, are so much to the point that they will, doubtless, meet with a ready response on this side. In the first instance the writer states that in England the cost per head, of the

more important public sanatoria is between £500 ($2,500) and £1,000 ($5,000). In Scotland satisfactory buildings have been erected for less than £50 ($250) a bed. The writer, commenting on this circumstance, remarks: "It may be well, perhaps, that some stately sanatoria should be erected, but it is important to remember that these should not be regarded as examples for general imitation. What is wanted is a large number of cheap sanatoria spread over the country as quickly as possible. One objection to the erection of imposing buildings is that suitability to the purpose in view is often sacrificed to architectural effect."

Dr. Lyon then discusses the question of the exaggerated ideas that now prevail with regard to the results that follow treatment in sanatoria. He says: "There is a general belief that if a man gets consumption, he has only to go to a sanatorium and he will come out restored to his former health. Unfortunately, this is not so; and it may be safely said that only a small percentage of patients undergoing treatment in London chest hospitals, even if they proceed to sanatoria, go back permanently to their work. Yet no public provision is made for the rest except the workhouse infirmary. A large number live on their benefit societies and friends, forming potent foci for the spread of the disease." The writer strongly advocates the establishment of colonies for consumptives, and proceeds to deal with the rational treatment of the disease. He concludes that the most important agent in preventing consumption, an abundant supply of fresh air, is neglected. At present the air of offices, private and public, is usually so foul as to render the unfortunate persons occupying them an easy prey to consumption. The same holds good for most theaters and other places of public resort.

Dr. Lyon's statements apply with as much force to America, with respect to the treatment of consumptives, as to Great Britain. Prevention must be the watchword in order to stamp out or even to check the spread of pulmonary tuberculosis. The conditions of life of the poor must be improved if progress is to be made in restraining consumption, and most assuredly public and private buildings of every description should be ventilated far more thoroughly than they are at present.

## Work and Worry.

Professor Osler, at the opening of the new medical buildings of the University of Toronto, delivered an eloquent address, a part of which he devoted to the discussion of the above subject. He told the students that the master-word, if they were ambitious of making good headway in their studies, and a name in after-life, was work. Carlyle defined genius "as an infinite capacity for taking pains," and although some may take exception to the definition as not entirely accurate, there is no doubt that steady work is essential to success. There are men of the most brilliant intellect who are cursed with a lack of perseverance, and so despite their distinguished ability either fail utterly in the battle of life, or disappointed and soured, merely exist. A slow, wilted person, endowed with capacity for hard work and who is the possessor of determined will-power, will nearly always win in the race. It is the case of the hare and tortoise over again.

Dr. Osler asked this question: "How can you take the greatest possible advantage of your capacities with the least possible strain" and answered it in this wise, "By cultivating system." He then went on to say: "Let each hour of the day have its allotted duty, and cultivate that power of concentration which grows with its exercise, so that the attention neither flags nor wavers, but settles with a bull-dog tenacity on the subject before you." In regard to the much-debated point as to breaking down in health from overstrain, the speaker had this to say: "I deny that work, legitimate work, has anything to do with this condition. It is that foul fiend, worry, who is responsible for a large majority of the cases. The more carefully one looks into the causes of nervous breakdown in students, the less important is work *per se* as a factor."

The opinions of Dr. Osler have been uttered times without number by great men. Work, unless carried to a degree incompatible with keeping the body in good physical condition, has hurt and will hurt no one. Students, however, must take a sufficient amount of outdoor exercise, and enjoy an abundancy of fresh air, in order to be able to effectually concentrate their thoughts and to attack their studies with zest. It goes without saying, that worry should be avoided as far as is possible, and to attain this object the ambitious student must forego many youthful pleasures which might give rise to causes for worry.

## The Insanity Question.

The *New York Evening Post*, November 21, publishes the views of Mr. Goodwin Brown on the reported increase of insanity. Mr. Brown holds opinions which are diametrically opposed to those of the great majority of authorities on the matter. Nevertheless, as for ten years he was a New York State commissioner in lunacy, his conclusions cannot but be respected and must carry a certain amount of weight. The writer states that during his experience and constant association with insane people, both he and his associates decided that the popular ideas as to the increase of insanity were wrong, and that, in fact, mental disorders were not increasing but decreasing. He puts down the erroneous views on the subject, which he thinks prevail, to misleading statistics, and points out that in the States outside New York figures relating to the number of the insane cannot be relied on, for the reason that patients are not all in State institutions, and there is no central authority, like the New York Commission in Lunacy, to compel private institutions to make a regular report of the number of their inmates. Consequently, proceeding on this line of argument, statistics concerning insanity—with the exception of regular institutions—are all guesswork, as many victims of insanity are cared for at home and are rarely reported as insane by their families. Therefore, the figures for the United States Census for 1899 must be eliminated. Mr. Brown does not contend that insanity has not increased, but does assert that there are no reliable figures to prove an increase. He also calls attention to the fact that our food has improved, our working hours are shorter, our hours for recreation have been lengthened, and these conditions, among others, tend to improve the public health, and as the public health grows better insanity decreases. Mr. Brown is also of the opinion that the nervous strain of city life is not apt to bring about a greater amount of insanity than the loneliness of existence in the country.

It is doubtless true that statistics concerning insanity in this country outside New York State are not to be depended upon, but how can the increase of insanity be explained in those countries in which fairly reliable figures are given? With remarkable unanimity medical men in charge of insane asylums in every country of the world declare that mental affections are increasing, and even allowing that statistics are somewhat falla-

cious, such testimony must count for something. While granting that the figures which go to show an increase of insanity may be exaggerated, and that the more careful mode of tabulating cases points to an apparent increase—which really does not exist to the extent imagined—yet it must be conceded when all has been taken into consideration, that there are proportionately more mad people than ever before.

Exception can likewise be taken to Mr. Brown's expressed opinion that the nervous strain of city life is not one of the most important factors in the production of insanity. It would seem but reasonable to suppose that city life under existing modern conditions cannot but exert a maleficent influence on the nervous system. The strain of work and worry is not all, but there must also be considered the ill-effects of vice and dissipation which are so prominent features of city life of the day. On the whole, when all the evidence has been sifted and carefully weighed, the judgment of those in a position to speak with authority would probably be that insanity has increased and is still making headway, although with less speed than is generally *believed* to be the case.

## News of the Week.

**Philadelphia County Medical Society.**—At a stated meeting, held November 25, Dr. Alfred Stengel read the report prepared by a committee "On the Control of Infectious Diseases by the Municipal Authorities." Among the recommendations made was the notification of cases of laryngeal and pulmonary tuberculosis, the notification by householders as well as physicians of the existence of communicable diseases, the establishment of a pay hospital for infectious diseases, the fixing of definite periods of quarantine for cases of scarlet fever, diphtheria, and smallpox, the discriminating placarding of houses in which there are cases of infectious disease, the proper disinfection of such houses after recovery, removal or death of the patients. The discussion was participated in by Drs. W. M. Welch, A. C. Abbott, Jay F. Schamberg, H. A. Hare, L. F. Flich, Edward Martin, A. A. Cairns, J. C. Cooper, H. C. Masland, Mordecai Price, A. B. Hirsh, James M. Anders, and others. It was pointed out that all of the necessary powers were conferred on the Bureau of Health by acts of the Assembly passed in 1818 and 1885.

**Philadelphia Neurological Society.**—At a stated meeting, held November 24, Dr. M. Allen Starr read by invitation a paper entitled "Is Epilepsy a Functional Disease, and Is It Ever Curable?" He has studied 2,000 cases of epilepsy, 1,750 in dispensary-practice, and 250 in private practice. He pointed out certain analogies between so-called Jacksonian or focal epilepsy and epilepsy of the ordinary or idiopathic type, and he showed that a close relationship exists between the symptomatology of the two types of disorder. In the one, as in the other, there is often an aura of fairly constant character and distribution, and the same is true in a measure of the motor disturbance. The differences appear to be in degree rather than in character. The similitude of the recurring attacks of ordinary epilepsy would seem to point a definite lesion in some part of the brain, and such an inference is supported by the not uncommon discovery of organic disease, though of varying character in different cases. The almost invariable presence of mental deterioration likewise is suggestive of such disease. Dr. Starr was, therefore, compelled to reach the conclusion that epilepsy, as a periodic and convulsive disorder of paroxysmal recurrence, is an organic disease, and, as such, is incurable by either medicinal or surgical measures. Relief may be afforded, both with respect to the frequency and the severity of the seizures, but actual cure, with assurance that there will never be a repetition of the attacks, cannot be anticipated; and this position is borne out by clinical experience, for there are on record few, if any, cases in which such recurrence has not taken place, perhaps even after an exceedingly long interval. Of course it was not implied that palliative measures should be neglected, and that every precaution should not be adopted and every therapeutic resource not employed to reduce the number and the severity of the attacks. Dr. Martin W. Barr, Medical Superintendent of the Pennsylvania Institution for Feeble-Minded Children, presented a communication in which independently he expressed views closely in accord with those that had been enunciated by Dr. Starr. His conclusions were based on a study of about eight hundred cases. In the discussion, which was participated in by Drs. Weir Mitchell, F. X. Dercum, Chas. K. Mills, W. G. Spiller, W. W. Keen, A. A. Eshner, J. M. Taylor, and F. S. Pearce, some dissent was expressed from the views put forth, although in reality the divergence of opinion was really less pronounced than it appeared to be. On the one hand it was contended that epilepsy is rather a disease of the entire individual, though with cerebral localization, and, on the other hand, that a good deal, if not actual cure, could be accomplished by intelligent treatment. Some of the lesions found after death, it was pointed out, might have been secondary.

**Typhoid Fever at Butler, Pa.**—A most severe epidemic of typhoid fever is reported raging at Butler, Pa., with a population variously estimated at from 12,000 to 18,000, the number of cases of typhoid is believed to be at least 1,000, four of the physicians of the place being among the sufferers. One physician broke down from the strain of trying to attend sixty-five patients all down with typhoid fever. There were fifteen deaths up to the beginning of this week. Dr. Benjamin Lee, secretary of the State Board of Health, who has been studying the situation at Butler, states that he found the epidemic to be due to a breaking down of the filter beds from which the town had been getting its water supply. After this all the drinking water was pumped from a creek which drained the town sewage. The whole town was obliged to use this water while the beds were being repaired. A relief committee has been organized and an appeal for physicians, nurses, and funds to fight the epidemic has been sent to Harrisburg and Philadelphia. It is stated that the citizens have not the means at hand of improvising temporary hospitals, and in many places four and five victims of the epidemic are crowded together in one room. Governor Pennypacker has instructed Dr. Lee to make a further examination into the condition of the epidemic and report, with a view to possible assistance by the State out of the fund of $50,000 created by the last Legislature for the suppression of epidemics.

**The Western Surgical and Gynecological Association.**—The thirteenth annual meeting of this association will be held at Denver on December 28 and 29, 1903, under the presidency of Dr. Alexander Hugh Ferguson of Chicago. An invitation is extended to the surgeons and gynecologists of the Great West to attend this meeting and take part in its deliberations. The meeting was appointed for the holiday week to enable those belonging to the teaching faculties of medical colleges to attend with-

out interfering with their college duties. There will be a symposium on "Prostatic Hypertrophy," and the preliminary program contains in addition the titles of twenty-five papers to be read at the meeting. The secretary of the association is Dr. George H. Simmons, 103 Dearborn Avenue, Chicago, and the chairman of the committee on arrangements, Dr. Leonard Freeman of Denver.

**Dr. Senn Suffering from Pyæmia.**—A despatch from Kansas City states that Dr. Nicholas Senn is ill at the Coats House in that city. He is suffering from an infection of the right hand, which resulted from a slight wound received during operation upon a pus case. We but voice the hopes of the entire profession that the trouble will be a slight one and that recovery will be prompt and perfect.

**An Isolation Hospital in Essex County, N. J.**—A site for an isolation hospital for contagious diseases has been chosen by a committee of the Essex County Board of Freeholders. It is to be for the use of all the cities and towns in Essex county. Many attempts have been made to establish a hospital of this sort in different places throughout the county, but every time there has been a vehement protest. The property selected is in Belleville, and there are forty-three acres in all. The price paid for the tract is $25,000. The hospital will cost in the neighborhood of $175,000.

**Dr. Edward F. Brush** was chosen mayor of Mount Vernon, N. Y., at the election recently held, having been the candidate on the victorious Republican ticket. He has appointed Dr. Archibald M. Cambbell president of the Board of Health.

**Reception at St. Vincent's Hospital.**—The medical staff of St. Vincent's Hospital gave a large reception on the afternoon of November 24, in the reception rooms of the hospital, from 4 until 6 o'clock, in honor of Archbishop Farley. Among the guests present were many clergymen and physicians, and persons of social prominence. A luncheon followed the reception. The committee of arrangements was made up of Drs. Frederick S. Dennis, chairman; Francis J. Quinlan, Constantine J. McGuire, J. M. Ferrer, Joseph D. Bryant, Charles Phelps, William R. Pryor, and George D. Stewart.

**Typhoid Fever at the University of Chicago.**—President Harper of the University of Chicago has warned the students against a typhoid fever epidemic at the university. Several cases of fever have developed in the last few days, and the authorities, fearing an epidemic, have made strenuous efforts to stamp out the disease before it gets a firmer hold among the students. At a special meeting of all the students, recently held Dr. Harper personally asked university men and women to do all in their power to help the authorities in their efforts to rid the university of the disease and prevent the classes having to be broken up and the students sent to their homes. The students were asked to leave boarding places where the water was not boiled and to take all other precautions.

**The German Emperor.**—There is a rumor current in Berlin that the throat trouble of the Kaiser is not progressing as favorably as it at first gave promise of doing. It is denied that there is any indication of malignancy, but the cord from which the growth was removed continues inflamed, and it is even thought a second operation may become necessary. The cable brings the scarcely credible report that Dr. Albert Robin of Paris has been called in consultation with the German physicians. Dr. Schmidt recently returned to Frankfort, Dr. Gustav Spies of the same city taking his place. Before leaving Potsdam Dr. Schmidt was elected an honorary member of the Berlin Laryngological Society.

**Illness of the Tsarina.**—The Empress of Russia is suffering from suppurative otitis media, and some alarm is expressed in St. Petersburg lest the inflammation spread to the mastoid cells.

**Southern Surgical and Gynecological Association.**—The sixteenth session of this assocation will be held at the new Piedmont Hotel, Atlanta, Ga., on Tuesday, Wednesday, and Thursday, December 15, 16, and 17, 1903, under the presidency of Dr. J. Wesley Bovee of Washington, D. C. Dr. Willis F. Westmoreland of Atlanta is chairman of the Committee of Arrangements. The preliminary program contains the titles of forty-six papers to be read at this meeting.

**The Senn Prize Essay for 1904.**—The committee on the Senn Medal begs leave to call attention to the following conditions governing the competition for this medal for 1904: A gold medal of suitable design is to be conferred on the member of the American Medical Association who shall present the best essay on some surgical subject. The award will be made under the following conditions: (*a*) The name of the author of each competing essay must be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the session at which the award is made, and the corresponding envelope is to be then and there opened and the name of the successful author announced. (*b*) All successful essays become the property of the association. (*c*) The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the association. (*d*) The competition is to be confined to those who, at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. (*e*) The competition for the medal will be closed on, and no essays received after, March 1, 1904. Communications may be addressed to any member of the committee, which consists of the following: Dr. James H. Dunn, Chairman, Minneapolis; Dr. M. L. Harris, 100 State street, Chicago; Dr. Floyd McRae, Atlanta, Ga.

**Mississippi Valley Medical Association.**—The thirtieth annual meeting of the Mississippi Valley Medical Association will be held at Cincinnati, Ohio, October 11, 12, and 13, 1904. Dr. B. Merrill Ricketts has been elected chairman of the Committee of Arrangements. The following are the officers of the association elected at Memphis: *President*, Dr. Edwin Walker of Evansville, Ind.; *President-Elect*, Dr. Hugh T. Patrick of Chicago, Ill.; *First Vice-President*, Dr. Bransford Lewis of St. Louis, Mo.; *Second Vice-President*, Dr. Geo. W. Cale, Jr., of Springfield, Mo.; *Secretary*, Dr. Henry Enos Tuley of Louisville, Ky.; *Assistant Secretary*, Dr. S. C. Stanton of Chicago, Ill.; *Treasurer*, Dr. Thos. Hunt Stucky of Louisville, Ky.

A resolution offered by Dr. S. P. Collings of Hot Springs, Ark., and adopted at the Memphis meeting was to the effect that "it is the sense of of the Mississippi Valley Medical Association that measures be taken by boards of health, boards of education and school authorities, and where possible, legislation secured, looking to the examination of the eyes of all school children, that disease in its incipiency may be discovered and corrected."

**Harvard Medical School Buildings.**—The Boston correspondent of the *Commercial Advertiser* says

that announcement has been made by the Harvard Corporation that the new Harvard Medical School buildings, in course of construction near the Fenway in Boston, will probably be ready for occupancy in the fall of 1905. The school will be located on a twenty-six acre plot, with a frontage of 945 feet on Longwood avenue. The granite bases of three of the six buildings have been put in place, and excavations for the others are well under way. Five of the six buildings, all of which will be constructed of white Vermont marble, are to be grouped about a court 520 feet long and 215 feet wide, while the sixth building will be used as a power house. The dental school building, included in the original plans, has been abandoned for the present. Three of the buildings are the gift of J. Pierpont Morgan, while provision has been made for the others from Mrs. Collis P. Huntington's contribution and part of the Rockefeller fund, together with $250,000 from a friend of the university. The school will have affiliated hospitals nearby, and several of the institutions to which the corporation has offered parts of the large plot belonging to the university have expressed a willingness to avail themselves of the offer. Among these are the Brigham, Children's, Samaritan, and Infants' hospital.

**Obituary Notes.**—Dr. CYRUS EDSON of this city died on December 2, at Roosevelt Hospital, of pneumonia. He had been ill only four days. He was born in Albany, N. Y., in 1857, and was graduated in Medicine from the College of Physicians and Surgeon in this city in 1881. While a student at Columbia College he was prominent in athletics and was a member of the Columbia crew that won the four-oar race at Henley in 1878. Soon after graduation he was appointed inspector in the Health Department, and served successively as chief of the bureau for the inspection of food products, chief of the bureau of contagious diseases, and sanitary superintendent. He was appointed by Mayor Gilroy Health Commissioner of New York City, and by Governor Flower Commissioner of Health of the State of New York. He was for three terms president of the Board of Pharmacy of the city and county of New York, and was for some time surgeon and lieutenant-colonel in the National Guard of the State of New York.

Dr. CHARLES SCHAFFER died of heart disease in Philadelphia on November 23, at the age of sixty-five years. He was graduated from the Medical Department of the University of Pennsylvania in the class of 1859, but owing to ill-health he was unable to devote himself exclusively to the practice of medicine, although he continued in active practice until five years ago. He was greatly interested in the natural sciences and their applications. He was particularly well known in the field of botany. He had a profound knowledge of the local species of plants and shrubs, and during many visits to British Columbia he made special studies of the mountain flora of that district.

Dr. WILLIAM SHAW STEWART died suddenly in Philadelphia on November 25 at the age of sixty-five years. He was graduated from Jefferson Medical College in the class of 1863, and shortly afterward was appointed an assistant surgeon in the Federal army, serving in that capacity throughout the war. He was one of the founders of the Medico-Chirurgical College, for a number of years professor of obstetrics and clinical gyecology, and for ten years dean. He was also one of the founders of the American Academy of Medicine. For nine years he was a director of the public schools and for many years a director of the Charity Hospital.

# Correspondence.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

HARBEN LECTURES—ANKYLOSTOMIASIS—RESEARCH PRIZES—MONUMENT TO ROYAL ARMY MEDICAL CORPS—GUY'S HOSPITAL—CHARING CROSS HEBREW WARD—ANOTHER HUXLEY LECTURE—LIVERPOOL UNIVERSITY—MISS HICKMAN'S DEATH—ROSS ON MALARIA—OBITUARY NOTES.

LONDON, November 13, 1903.

THE Harben Lectures before the Royal Institute of Public Health, delivered in October by Professor Hueppe of Prague, naturally attracted attention, both from the immense influence of the lecturer and the subject treated. The philosophical views of disease which he has taught for the last ten years have only gradually penetrated the conception of many actively engaged in practice, and even in research, and it is well he should have had an opportunity of laying them before us by means of examples. Close study of external causes might lead to exaggeration of their importance, as compared with constitutional causes. In both specific germs are found. Pasteur and Koch's work led many to hold the germ as the sole cause; Goodsir and Virchow looked to the diseased cell. Simon, Parkes, and others in England, and Pettenkofer in Germany, attributed a considerable part to "predisposition of place and time." Professor Hueppe recognizes the importance of all these three views. He said predisposition, denied by some, must be reckoned with. He did not regard it as something negative as opposed to immunity. Immunization proved the existence of predisposition. We know that predisposition may alter with age, and may be influenced by external conditions, such as cold, heat, hunger, or alcoholism. Also, perhaps, mixture of races, to judge by Kruse's observation on the location of cancer in Italy. Germs are not the entity of disease; they may be present in healthy persons; they may live outside the body as saprophytes; they do not affect different animals alike. Again, different germs may produce similar effects and different individuals behave differently toward infection. It cannot then be admitted that either the germs or the body cells are an entity in the process. The cellular pathologist may err by only considering the structure; the bacteriologist by concluding that his experiments with pure cultures are equivalent to what takes place in naturally acquired infections. In proof of the last point the guinea-pig, though highly susceptible to laboratory infection with the tubercle bacillus, practically never becomes infected naturally.

In his second lecture Professor Hueppe explained the views of Ehrlich, Bordet, Pfeiffer, and others as to the mode of action of bactericidal sera. He quoted his own statement in 1895 that "The property of specificity may not unreasonably be conceived as a quantitative variation, and as dependent upon the bringing into action of normal powers by appropriate stimuli." This conception has since been accepted by Ehrlich and others. Immunization, he looks upon as only the augmentation of faculties which are performed as disposition. Predisposition he held to be positive, but it cannot protect the body against infection.

In his concluding lecture Professor Hueppe considered tuberculosis. Here we have both the bacillus and predisposition to deal with. Laboratory experiments in which large numbers of bacilli are introduced at once are quite different from what takes place in ordinary infection. That tuberculosis is often cured necropsies prove. Virulent bacilli have been found in the air passages of healthy persons who have associated with patients. Tuberculosis is so general that everyone may be exposed to it, but the majority remain healthy. The lecturer opposes Koch as to the intercommunicability of bovine and human tubercle. Behring found bacilli which did not at first infect cattle, but did so after passing through the goat. Anthropoid apes have been infected with both bovine and human bacilli, and cattle have been rendered immune to bovine by treatment with human tubercle bacilli. The two bacilli must, therefore, be varieties of one species. Similar observations have been made as to other bacteria. On Koch's discovery it was thought that the bacilli in pulmonary phthisis entered only through the air passages, but Hueppe and others have shown that they may reach the lungs through the lymphatics, or the circulatory systems. Rabbits fed with tuberculous material develop intestinal disease in some and pulmonary in others. The *locus minoris resistentiæ* is the lungs of adults, the intestines of children. The fight against bacilli will not suffice alone. We must also increase the powers of resistance by hygiene. It is too early to estimate the value of immunizing experiments, such as those made by Macfadyen and Behring.

Yesterday a conference was held at the Home Office between representatives of coal owners and miners in

England and Wales, with reference to the outbreak of ankylostomiasis in British mines, for the purpose of determining the steps which ought to be taken to prevent the spread of the disease.

The conclusions reached were that the time has not arrived for promulgating special rules; that local conferences should be held in the various districts; that the Home Secretary should arrange for special examination of any mines seriously suspected of being infected, and that he should be asked to circulate information as to the diagnosis and treatment of the disease among medical practitioners in mining districts, and also, in a more popular form, among the persons engaged in the mining industry.

In regard to the last recommendation a good deal of information may be found in Dr. J. S. Haldane's report to the Home Secretary on ankylostomiasis in Westphalia, which was issued at the beginning of this week. The doctor was greatly impressed with the knowledge, and vigorous initiative displayed by the managers of the two chief colliery companies, and thinks the experience obtained will be most valuable in preventing the spread of the disease in England. The most important measures are (*a*) the exclusion of infected men from underground work, (*b*) sanitary underground improvements. He urges the necessity of further researches into the pathology of the disease, the mode of infection, development of the larvæ, diagnosis, disinfection, and the best forms of sanitary receptacles for underground use. Further, the organization of the means for examination of suspected cases should not be delayed.

The Craggs' Research Prize of the London School of Tropical Medicine, for the best piece of original work done during the current year by present or past students, has been awarded to Dr. Aldo Castellani for his researches on sleeping sickness. He lately returned from Africa, where, as I reported to you, he isolated a microbe and pointed out the association of the disease with trypanosomiasis. Dr. Travers has been awarded honorable mention for his paper on beriberi.

A monument to members of the Royal Army Medical Corps who lost their lives in the South-African campaign is to be erected at Aldershot. It will take the form of a granite obelisk, and on a marble plinth will be engraved the names of those who fell. The entire cost has been defrayed by subscriptions from past and present members of the corps.

Guy's Hospital is still in financial difficulty. At the annual Court of Governors the treasurer stated that with a cost for maintenance of £60,000 a year there was only an income of £35,000. In addition the King's and other funds had of late given £11,000, but, even so, there remains a deficit of £14,000. Of the £180,000 appealed for in 1901 only $103,000 has been received, and the hospital is in debt for the balance on temporary loans. The court resolved that "the treasurer be requested to obtain the widest currency possible for a short statement of the present circumstances of the charity, and further, to continue a vigorous appeal with a view of enlarging the basis of public support adequately to the increased needs of the establishment."

Yesterday the new Levy ward of Charing Cross Hospital was formally opened by the generous donor, Miss Matilda Levy. It is for female Jewish patients primarily, but not exclusively. A separate kitchen, larder, and pantry are provided.

The libel action against Stephen Coleridge by Dr. Bayliss, the assistant professor of physiology at University College, is now being heard in the King's Bench Division of the High Court before the Lord Chief Justice and a special jury. The libel alleged was in the speech at an antivivisection meeting where Mr. Coleridge accused Dr. Bayliss of a specific act of torture to a dog in a demonstration at the college.

The University of Birmingham is to have a Huxley lecture delivered annually, an anonymous friend of the late professor having provided the endowment. He is desirous that the first lecture should be given by some one who knew Huxley personally, and if possible who was associated with his work. It is proposed to invite Sir M. Foster to give the first lecture.

The new University of Liverpool was inaugurated with due ceremony on the 5th inst., when the Chancellor received from the Lord Mayor the charter of incorporation. It was a day of mutual congratulations between the medical school, the University College, and the citizens of Liverpool.

On the 10th inst. Major Ronald Ross lectured on "Malaria and the Duty of the State to Prevent It," at the Royal Colonial Institute. He holds that the State must protect its subjects in spite of themselves, for his experience convinces him that it is futile to trust to individuals exercising constantly proper precautions. Probably, he thinks, a majority of the white population in Africa do not yet apprehend the full import of the mosquito theory.

The coroner's inquiry into the death of Miss Hickman, the lady doctor whose disappearance from the Royal Free Hospital made such a sensation, was concluded yesterday. The verdict was that "she died from poisoning by morphine sulphate, self-administered at a time when she was temporarily insane."

Sir Charles Nicholson, Bart., died on Sunday at the great age of ninety-five years. He took his M.D. at Edinburgh in 1833 and the next year went to Australia, where he practised. In 1843 he was elected a member of the first Legislative Council of New South Wales, of which body he was elected speaker three times. He was knighted in 1852 and made a baronet in 1859. He was the first Chancellor of Sydney University (from 1854 to 1860), and to its museum he presented his splendid collection of Egyptian antiquities.

Surgeon-Major-General James Davis of the Army Medical Staff died suddenly at Southsea, on the 8th inst., aged sixty-eight years. He qualified in Dublin in 1855–6 and entered the army in 1858. He served in the New Zealand wars of 1861 and 1865, taking part in the repulse of the attack on the camp at Nukumaru and the affair of Kakaramea. He held the New Zealand medal, reached the rank of surgeon-major-general in May, 1894, having served as P.M.O. to the southern division from January. In the following April he went on the retired list.

Philip B. Mason, M.R.C.S., J.P., surgeon to the Burton Infirmary, died on the 6th inst. He was a man of great talents. As a student he carried off a great number of prizes at University College when Sir. J. Williams, Sir R. D. Powell, Sir W. R. Gowers, and others were fellow-students. The death of his father compelled him to leave in 1866 before taking the University degree. He had been demonstrator of anatomy, and but for the necessity of taking up his father's practice would probably have continued teaching at the college. All his life he was a collector of natural objects. His museum of entomological specimens is of great dimensions—probably excelled by none if any.

## THE PROFESSIONAL VS. THE TRAINED NURSE.

To the Editor of the Medical Record:

Sir: Some time ago the subject of the education of nurses was considered in the Medical Record in the hopes of bringing some kind of response from members of the medical profession, and opening up the question in a radical and fundamental manner. But no response came, though the question has been touched upon in more recent issues of the Medical Record. However, good material for opening up the subject may be found in an article in the Medical Record of September 26, which probably represents the conservative and general opinion of the medical profession. In this contribution it is said that, "thanks to the great advance made in nursing in our day, we physicians can usually have our directions and treatment of patients intelligently and faithfully carried out if we constantly have the courage to insist upon what is best for the well-being of our patients and our moral self-respect. I am not quite sure that the nurse's realization of the doctrine of self-sacrifice and devotion has continuously improved. I am also convinced that more than one subject nurses are taught at some length in the schools had better be let alone. This acquired smattering of anatomy, physiology, and therapeutics is often of practical detriment in the rôle of the nurse. They are tempted, with imperfect knowledge, to give counsel or direct at times when they should seek only to comfort and serve."

The name of the author of the above is purposely omitted in order to avoid every appearance of personal polemic in the advocacy of opposing opinions. For the same and other reasons, the writer assumes a nom-de-plume. Ideas are only of value as they prove true. The author is simply a vehicle, as his pen is, and amounts to nothing. The days of ambition for honors or notoriety have passed. The primary and fundamental question is the amount and character of the instruction given to nurses or asked for by them, and may well be introduced by requoting the following: "That more than one subject nurses are taught at some length in the schools had better be let alone. This acquired smattering of anatomy, physiology, and therapeutics is often of practical detriment to the nurse. They are often tempted, with imperfect knowledge, to give counsel or direct at times, when they should seek only to comfort and serve."

Admitting that the accusation is true in many cases, is it not equally true that the real trouble lies in the very "smattering of imperfect knowledge" on the part of the culprit? Is it not this "smattering" which con-

stitutes the dangerous thing or "little knowledge" complained of in the well-known and oft-quoted saying. Would not a more fundamental, and at the same time broader, education in scientfic fundamentals remove or nullify the very danger mentioned? Would not more knowledge with specific education in its professional application enable the intelligent nurse to better understand her place and keep her professional position, both in regard to the attending physician and patient? The trouble seems to be just where it has been placed, but with quite the contrary meaning—that is, in the "smattering of imperfect knowledge" now wofully given to nurse students in the so-called training schools. Not only does the trouble lie in the "smattering," but the manner of applying it to the needs of the nurse is still more culpable. It is neither the "fish, flesh, nor fowl" of education, and is practically indigestible for either medical student or student nurse. It is a sort of half-way nondescript unsuitable for any specific purpose. In a certain sense the lectures to nurses are mostly voluntary, and it has often happened that lectures are scheduled for certain hours, and no lecturer has appeared for a week, thus disappointing as well as demoralizing the nurse students. No serious study has yet been given to the proper adaptation of what may be termed medical education to the needs of the nurse, and, as previously intimated, the stuff they do get is not suitable to the medical student, and being a most indigestible digest of what is generally offered to medics is equally unsuitable to the nurse student. The education of nurses should be far more in the hands of especially gifted and educated nurses than at present. Even the physician or surgeon lecturer should know intimately the requirements of the nurses and have the power of special adaptation, and have time and enthusiasm to apply himself or he is unfit. The question of education in any line is fully as much in the specific adaptation of what is offered to the needs of the student as in the material itself. Too much education is to be likened to good food improperly cooked and totally unadapted to the digestive apparatus of the patient.

*Profession or Trade*—That is the question. Does not the issue before us find its counterpart in the medical profession? Is it not what all earnest thinking men have combated and are still combating? Should we not then uphold the endeavors of the most intelligent nurses for the better education of their class in our own self-interest? Certainly the intelligent public has no less interest and the unintelligent will be equally benefited. In medicine do we not have the educated professional, the physician, and have we not still with us the graduate of the medical hotbed, with his "smattering of imperfect knowledge," the trade-doctor? It is the trade-doctor the medical profession has been endeavoring to purge itself of as an undesirable parasite, and it is the trade-nurse, with her "smattering of imperfect knowledge" that must be purged out of the ranks ere we can have the more desirable and better-educated professional nurse. The question is, if the better class of nurses are ready and anxious to take the medicine, should not we physicians prepare and administer the dose? Cannot the nurses say to us "why stand ye idle here?" On all other questions of education we have come to the conviction that "a little knowledge is a dangerous thing," and that the most exact and fundamental education possible is the only remedy against social anarchy; but in regard to the education of nurses our most learned colleague would have even the "smattering of imperfect knowledge" removed "because the semi-educated nurse raises anarchy in the house by giving counsel and directing where the properly educated nurse would not. Is not the real remedy to be sought in following the adage to "take another bite of the dog that bit you": not only a "bite" but to consume the whole digestible part of the carcass? By education alone can the "trained (trade) nurse" be abolished and the professional nurse, in her way the equal of the professional physician, become a gloriously creditable member of society. It is the "trained nurse," with her "smattering of imperfect knowledge," that raises anarchy with the patient, as it is the trade-doctor who does the same thing. Both have that dangerous disease, *macro-cranialis giganticus*, the only remedy for which is more and better fundamental education. The trained nurse of to-day is simply a more or less perfectly drilled machine and not at all educated in the professional sense. Which is better for us physicians, to remove the "smattering" of knowledge the nurse may now possess and increase the trade-training, or augment the knowledge and thoroughly teach the nurse student how best to apply it to her own interest? Please do not jump on that ye altruistic emotionalist. Know ye not that he who serves himself intelligently (with all that word implies) will give the best possible service to others.

Who has not met a "trained nurse," a most highly approved graduate of some recognized training school, well drilled in all the tactics of her trade, absolutely without even a "smattering of knowledge" in anything but the trade sense, but unquestionably competent in that sense, whose looks and manners were that of an ill-bred person who murdered the King's English "to absolute distortion, who was without active intelligence and yet so well drilled as to automatically do her work? Is not the picture only too true? That is the kind of nurse our most distinguished colleague seems to advocate. Even such as that may have her place, in some wards in a hospital where refining influences are uncalled for? On the other hand, are we not straining every nerve in our endeavors to free ourselves from just that class of society? The educated and refined nurse in the hospital is a strong power in the elevation of such inmates. Again, the trade-nurse may be useful during an operation, or in the worst stages of a dangerous disease, when the patient is indifferent to surroundings; but of what value is such an ignoramus in the convalescence of a refined and educated patient? The thoroughly educated and refined professional nurse can do all the best of trade nurses can, and more still, and is to be depended on in emergencies where the drilled machine would stop short for want of intelligence and that education which makes a person active and reliable. The best trade nurse is to be compared to the old-time "able seamen" who knew all the details of his trade, but was absolutely useless to direct the work and generally completely demoralized without the guidance of the educated officer in case of disastrous emergency. As things are, too many nurses are of the trade-nurse type. Is not the medical profession ready for the truly professional nurse? The better educated and more refined portion of the public certainly demands them. They are equally necessary to the service of the less educated and cultured.

The writer has ever been an opponent of private, semi-public, or even endowed educational institutions for any branch of education having to do with fitting persons for the public service. If any branch of that service is especially public and should be controlled for and by the best representative public intelligence, it is the medical profession of which that of nursing is an inseparable part. As things now are, the hospital is the training school, but it can never become the school for the fundamental education of student nurses. The student nurses in hospital training schools are so driven with trade-work that it is impossible for them to find time for detailed study and critical thought over the conditions presented by patients. What knowledge they do get is too much of the "pick-up" type. It is a veritable "prostitution" of the name education. It is "drill, ye tarriers, drill," until all energy is fairly trained out of the unfortunate nurse candidates. The only recourse is, as stated in a previous article, for the public to establish preparatory or normal schools for the instruction of student nurses specifically and broadly in the scientific fundaments of their profession, by persons especially qualified by study and experience to adapt that knowledge to the needs of the professional nurse. This question of the specific fundamental education of the nurse will be treated in a future communication.

MEDICUS.

## AMERICAN AND INTERNATIONAL CONGRESSES ON TUBERCULOSIS AND TUBERCULOSIS EXHIBITS FOR THE YEARS 1904 AND 1905.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: During the past few months I have been the recipient of a large number of inquiries concerning the various tuberculosis congresses (American and International) which have been projected for the years 1904 and 1905. The multiplicity of these various congresses and the similarity of their names leads naturally to great confusion. It would be really too great a task to undertake to answer in full and individually all the letters with which I have been honored. I therefore ask you to grant me the space to give the desired information in your esteemed paper, so that all the readers of the MEDICAL RECORD who may be interested will have a clear idea of the various congresses, their officers, and time and place of meeting.

It is announced that a congress on tuberculosis is to be held in St. Louis on October 3, 4, and 5, 1904, under the name of "International Congress on Tuberculosis." Upon careful inquiry I have learned the following facts about this congress: Mr. Francis, the President of the St. Louis Exhibition, has been approached by the officers of the "American Congress on Tuberculosis," which was founded some years ago by Clark Bell, Esq., a lawyer of New York, to sanction the holding of an international congress on

tuberculosis in connection with the Louisiana Purchase Exposition. From a letter received from Dr. E. J Barrick of Toronto, Canada, the now president of this "American Congress," I learned that Mr. Francis has appointed the above mentioned Mr. Clark Bell chairman of the Committee on Organization. Mr. Clark Bell is also the treasurer and chairman of the Executive Committee of the "American Congress on Tuberculosis," season 1903-1904; Mr. Samuel Bell Thomas of 290 Broadway, New York, is the secretary of the latter. The officers of the International Congress are not yet elected. I was desirous to learn the names of other medical men interested in this congress, and Dr. Barrick very kindly wrote me on November 16 that he had asked Mr. Bell to furnish me the desired additional information, but nothing has thus far been received.

The other international tuberculosis congress announced is the one to meet in Washington, D. C., April 4, 5, and 6, 1905. It is to be held under the auspices of "The American Congress on Tuberculosis for the Prevention of Consumption." The following is a list of the officers of this latter organization: *Honorary President*, Dr. Henry D. Holton, Brattleboro, Vt.; *Member Executive Council*, Dr. Chas. O. Probst, Columbus, Ohio.; *President*, Dr. Daniel Lewis, New York; *Vice-Presidents*, Drs. E. A. Egan, Springfield, Ill.; Frank Paschal, San Antonio, Tex.; Irving A. Watson, Concord, N. H.; Chas. Wood Fassett, St. Joseph, Mo.; *Secretary*, Dr. George Brown, Atlanta, Ga.; *Treasurer*, Dr. P. H. Bryce, Toronto, Canada.

Before going any further I wish to call the attention of the readers to the difference in name of the two American congresses. The one is "American Congress on Tuberculosis," the other "The American Congress on Tuberculosis for the Prevention of Consumption."

The congress which was to meet under the name of "Congrès International de la Tuberculose" at Paris from September 26 to October 1, 1904, has been recently postponed to the year 1905. The president of this congress is Professor Brouardel, Hon. Dean of the Faculty of Medicine of Paris. The general secretary is Dr. M. Letulle, professor agrégé of the Faculty of Medicine, residing at 7 rue Magdebourg, Paris. This congress will be divided into two sections, the medical and the social: I. In the medical section the following subjects will be discussed: (1) New methods for the treatment of lupus; (2) New methods for the early diagnosis of tuberculosis; (3) Comparative studies on the different forms of tuberculosis.

II. In the social section: (1) Etiological factors in tuberculosis; (2) Value of different means for the treatment of tuberculosis; (3) The voluntary insurance and the mutual societies in the combat against tuberculosis.

The congress will furthermore form a technical section under the name of "Museum of the Congress."

There will be held during the coming year independently of the above-mentioned congresses two tuberculosis exhibitions, one in Baltimore, Md., and the other in St. Louis, Mo. The Baltimore Tuberculosis Exhibition will be held in January, 1904, under the combined auspices of the Tuberculosis Commission, the State Board of Health, and the Maryland Public Health Association. Details are in charge of Dr. W. S. Thayer, president of the commission Mr. John M. Glenn, secretary; Dr. John S. Fulton, secretary of the State Board of Health, and Dr. Marshall L. Price. Dr. Henry B. Jacobs has been elected chairman, and 250 prominent professional men and laymen have been asked to act as an advisory committee. A series of lectures will be given, the object of which will be to present the extent and effects of the disease in a striking manner. The pathological, hygienic, sanatorium, and sociological aspects of the tuberculosis problem will be practically demonstrated by specimens, charts, literature, instruments, photographs, and plans. All communications concerning the exhibition should be addressed to Dr. Marshall Langton Price, 10 South Street, Baltimore, Md.

The other tuberculosis exhibition will be held in St. Louis, in connection with the Exhibition of Social Economy and under the Sub-section of Hygiene, of which Dr. J. N. Hurty of Indianapolis is superintendent. To avoid multiplicity of exhibits, Dr. Hurty has put himself in communication with the General Secretary of the International Bureau for the Prevention of Consumption at Berlin, Professor Pannwitz, so that the exhibits which the European countries contemplate sending shall also come under his direction.

All indications point toward the success of both exhibits, and it is to be hoped that they will fulfil their high purpose and at the same time be a credit to American physicians and hygienists.

Considering the various congresses, I do not hesitate to express a feeling of deep anxiety. The first one mentioned, which, for reason of brevity, I will call "The Bell Congress," because it owes its inception to Mr. Clark Bell, has, to my knowledge, not the support of our best known men in the field of clinical medicine, hygiene, tuberculosis pathology, or tuberculotherapeutics.

The second congress, in point of time, which again, for sake of brevity and clearness, I may call "The Lewis-Brown Congress" (names of the president and secretary), while it has many distinguished men of various State and provincial boards of health among the members, has, like the Bell Congress, thus far not among them the men we are wont to look up to as leaders in movements of this kind. No such men as Biggs, Billings, Bowditch, Flick, Jacobi, Janeway, Klebs, Osler, Otis, Trudeau, Tyson, are connected with this congress.

What are our confrères across the water to think if they hear of two American congresses on tuberculosis and each having an international one under its auspices? The European authorities found it best, instead of having a triennial congress, to have one more year to intervene. This will make the congress in Washington and the one in Paris convene in the same year (1905).

I hope this letter, in which I would address the medical profession in America, may result in a satisfactory solution of this very complicated problem. If President Francis of the St. Louis Exposition desires that a tuberculosis congress shall be held in St. Louis, let him call to his aid some of the men whom I have mentioned as leaders in our profession. They will consult with him on the advisability of such a congress, and if it is decided that one should be held, Mr. Francis can be assured that the best element of Europe and America will come to St. Louis to contribute to its success.

The officers and members of the Lewis-Brown Congress must realize that they cannot expect that their international meeting in Washington will be successful, when, six months later, there will be an international congress in Paris. I hope that there will be enough patriotism and national pride for all interested to realize that two American congresses on tuberculosis is an anomaly, and that, if the St. Louis Congress is to be a success, it must be in the hands of medical men well and favorably known in this country and abroad.

As a solution of the problem I beg leave to suggest the following: During the Tuberculosis Exhibition in Baltimore next January, all interested should meet at a certain date on this neutral ground for the purpose of coming to an agreement about a single representative national or international tuberculosis congress to be held in America. There, too, should be formed a national committee on tuberculosis which will be in touch with the international tuberculosis congress which will convene in Paris in 1905.

S. A. KNOPF, M.D.

16 WEST NINETY-FIFTH STREET.
NEW YORK.

*The Boston Medical and Surgical Journal, Nov. 26, 1903.*

**Diseases of House Officers in Hospitals.** — William R. P. Emerson presents certain conclusions from a study of this subject. The records indicate that the danger to house officers of pneumonia, phthisis, or typhoid fever is very small. Nasopharyngeal and febricular affections occur in the ratio of 12 to 1. The danger of infection in the examination of moist cultures and sputum is very slight. In a six months' service the chance of diphtheritic infection is 1 in 2, of scarlet fever infection, 1 in 7. The influence of improved living quarters and facilities for proper exercise upon the health of the men is marked. The sense of fatigue occurs most often in the hospital as the result of nervous tension and indoor air rather than of muscular exhaustion, and is relieved by proper exercise and baths.

**A Case of Post-typhoidal Myositis of the Rectus Abdominis.**—David D. Scannell reports the case of a boy aged nine years, who, after beng discharged from the hospital after recovery from an attack of typhoid fever, was brought back again in a few days. He was suffering from pain in the abdomen, most marked in the umbilical and hypogastric regions. The diagnosis of acute perforative appendicitis was made and the abdomen was opened. Both appendix and peritoneum were normal. Exploration of the intraabdominal surface of the anterior belly wall showed an ovoidal, indurated, nonfluctuant, extraperitoneal thickening of the right rectus muscle in its lower third, extending from just below the umbilicus to just above the symphysis pubis. The appendix was removed. Twenty-four days after the operation the parietal induration had completely disappeared. Post-typhoidal myositis is extremely rare, and this case is one of much interest.

**The Treatment of Diffuse Peritonitis.**—B. F. Lund believes that whatever methods are adopted a large

mortality will always attend the surgeon's efforts in those cases of diffuse peritonitis which come to him late. The most important point of the treatment is to remove the infecting focus immediately. The writer is not an advocate of the "waiting" policy. A complete removal of all necrotic tissue is indicated whenever possible. After the infecting focus has been thoroughly removed, the peritoneal cavity should be carefully cleansed. The writer irrigates the peritoneal cavity with decinormal salt solution at a temperature of 110°. Several quarts or gallons of salt solution are introduced through a long glass nozzle of large caliber which is rushed into all the recesses of the cavity. The water rushes out of the wound, bringing fragments which would otherwise have caused long suppuration. A part of the salt solution is left behind. This is absorbed and increases the amount of fluid in the vascular system. Another part of the fluid is taken up by the drainage gauze and starts a current from the abdomen out into the dressings, and helps to remove any infectious material that remains behind after the irrigation. The writer advocates the use of gauze drainage. He elevates the head of the patient's bed, about one foot above the level, by placing under the head of the bed the blocks which are ordinarily used to elevate the foot of the bed in case of fractured femur. One or two pillows are placed beneath the shoulders. The fluid then flows from the flanks into the pelvis, and the position is not so exhausting as is the more complete upright position.

*Journal of the American Medical Association, Nov. 28, 1903.*

**Removal of the Faucial Tonsil.**—The paper of C. M. Robertson is an exploitation of the use of the scissors.—a special shape of which he has devised. It is hardly correct to say, as does the sub-title of his paper, that this is a "new method of operation." The paper is, however, a good exposition of the general subject of tonsillar development and the measures for removing diseased tonsils.

**Etiology of Yellow Fever.**—J. Carroll who has made bacteriological studies on the subject, offers the following conclusions: (1) The fusiform stage of the so-called *Myxococcidium stegomyiæ* of Parker, Beyer, and Pothier (1903) is not connected in any way with the transmission of yellow fever. (2) This organism appears to be not a protozoan parasite, but a yeast fungus. In its fusiform stage, the only form in which it was constantly present, it shows the characteristic budding, staining affinities and vacuolation or spore formation of a blastomycete, and it is found with considerable regularity in both male and female mosquitos that have purposely been fed on overripe banana to which a pure culture of a wild yeast had been added in the laboratory. (3) The organism has not hitherto been found in repeated examinations of mosquitos of the genus *Stegomyia* that have bitten yellow-fever patients in the early stages of the disease, when such insects had been fed only on blood, dry sugar, and water. This statement applies also to mosquitos that are known to have reproduced the disease in human beings.

**The Causes, Prevention, and Management of Myopia.**—The views of J. H. Claiborne are thus summarized: (1) Myopia is a condition in which there is an increase in the anteroposterior diameter of the eyeball. This condition is, except in very rare cases, acquired. It is a distinctly vicious process, and in the great majority of cases tends to increase. It should, therefore, be regarded as a disease. It usually begins in childhood. (2) Its causes may be divided into predisposing causes and a direct cause. (3) (*a*) The predisposing causes are, in general terms: Heredity, naturally lax conditions of the eye tunics in certain individuals; the injudicious use of the eyes after sickness, usually in children, after the exanthemata; bad illumination, improperly placed illumination, incorrect position in the act of reading; the existence of refractive errors, generally astigmatism, which is uncorrected or improperly corrected; corneal opacities; any systemic condition which tends to produce cerebral congestion—for example, constipation. (*b*) The direct cause is an elongation of the eye on its anteroposterior axis, at the posterior pole, except in the case of corneal astigmatism. (4) When myopia has once been acquired, its increase is directly caused by the pressure on the globe by the extrinsic muscles, due to the convergence of the visual lines toward the far point—the convergence theory. (5) The weight of evidence and reason is distinctly against the accommodative theory. (6) Theoretically, full correction of the myopia is indicated, whereby the far point is thrust to infinity. (7) Practically, this is not always possible. (8) The far point should be thrust as far as possible toward infinity, but, at the same time, it should be compatible with the best vision and the greatest comfort.

*Medical News, November 28, 1903.*

**A Discussion of Some Common Forms of Liver Disturbances.**—A. P. Stoner first considers hyperæmia of the liver. This condition is produced by the ingestion of an ordinary meal. Highly spiced foods and alcoholic beverages produce excessive hyperæmia. More or less congestion of the liver may accompany valvular heart disease. The writer believes that the two conditions, sudden suppression of the menses and hemorrhoidal bleeding, considered by many authorities to produce hyperæmia of the liver, probably have very little effect upon the organ. As to cirrhosis of the liver, while many factors seem to be responsible for cirrhosis, none will produce the changes met with except the cause be long continued. The liver tissue possesses a remarkable capacity for regeneration. There is reason to believe that all liver cirrhosis is the result, whether directly or indirectly, of infection. It is not essential that the propagation of bacteria take place within the liver, for this process may occur in other organs of the body, but their toxins are carried to the liver and cause the death of the liver cell. Fibrous and connective tissue fill up the gap caused by the broken down cell, and cirrhosis is the result. Alcohol is undoubtedly responsible for a large number of cases of cirrhosis in children. Abnormal fermentation in the bowels is responsible for a large percentage of cirrhosis in both children and adults.

**Diet and Drugs in Nephritis.**—William S. Gordon states that the health of the kidney depends, in a great measure, upon the normal metabolic and depurative work of the liver, upon the state of the genitourinary tract below the upper opening of the ureter, upon the cutaneous circulation and vasomotor influences, and upon the absence of pressure and traumatism. An exclusive milk diet may do harm by being abused and furnishing too much urea, by causing constipation and absorption of toxins, by failing to supply the blood with sufficient nourishment, or by setting up lactic or butyric fermentation. A routine diet for all cases is unscientific and should be avoided. There are a large number of cases in which a diet composed wholly or largely of milk is beneficial. Abstinence from alcohol, tea, coffee, and coca, and a partial or complete reduction of sweets and acids, with the use of alkaline waters, are means promptly beneficial in acute cases and in the first stages of the chronic cases. Fowl, game, fish, and eggs should not be indulged in to excess because butcher's meat has been prohibited. An efficient cholagogue given before the diuretic, or in conjunction with it, is a powerful auxiliary in the treatment. Diaphoretics are very useful. In cases of acute nephritis with high pulse tension and diminished flow of urine, nitroglyerin is invaluable. In chronic nephritis iron is most serviceable. Chloral hydrate, the bromides, and morphine are useful. Taken all in all, strychnine is the best remedy we have for weakness and exhaustion of the nervous system, while its combination with the hypophosphites will sometimes give results better than can be obtained from either drug alone

**The Best Method of Dealing with the Stump in Appendicectomy.**—Howard Lilienthal discusses two objections which have been made to the ligation and cauterization of the stump of the appendix. It has been stated that when the appendix is ligated, mucous surfaces are brought into contact, and as mucous membranes will not adhere to each other, the stump formed in this way is insecure. The ligature has been proved to be secure, and the mucosa has been shown to be cleanly cut by the constricting ligature. The submucous coat and the peritoneum in the specimens examined have been uncut and held firmly. The hardened sections confirm the conclusions drawn from the observation of the recent specimens. The second criticism is that adhesions are apt to form. The writer has examined into the postoperative conditions in a number of cases treated by ligation and cauterization. In three cases of fatal peritonitis, examined from three to six days after the operation, there were adhesions almost everywhere else, but not at the stump. This had been thrown off with its ligature and only a smooth cicatrix on the surface of the cæcum remained. In a number of other cases, examined months or years after the first operation, the former site of the appendix was marked by a minute smooth white cicatrix. No adhesion was ever found in this location. The writer believes that the formation of the stump by the method of ligation is the only way in which adhesions at this point may be certainly avoided. He prefers cauterization by strong carbolic acid. He takes up a minute drop of the 95-per-cent. solution on the tip of a closed artery clamp, and after protecting the surrounding tissues, he applies the acid thoroughly

two or three times to the mucous lining of the stump. In from fifteen to thirty seconds the stump is dropped back into the abdominal cavity.

*New York Medical Journal, November 28, 1903.*

**The Use of Weak Cocaine Solutions in Operations for the Removal of Tumors.**—F. Griffiths reports six cases of respectively fibrolipoma of neck, sebaceous cyst of scalp, tuberculous glands of neck, glandular swelling of neck, papillomatous growth of scalp and cervical cyst. He uses ½ to ¼ per cent. solutions in weak soda menstruum.

**Ocular Headache and Other Ocular Reflexes; a Statistical Study.**—The paper of M. W. Zimmerman, based on two thousand cases, must be consulted in the original, as it does not easily lend itself to abstracting. Concerning the results of treatment he notes that his tables contain seven hundred and ninety-four cases in which the result of treating headache by the correction of an optical error is recorded. He reports 86 per cent. of cures, using the word "cure" in the sense of such a profound modification of the symptoms that the patient is no longer suffering any annoyance which cannot be controlled by a little attention to ocular and personal hygiene.

*American Medicine, November 28, 1903.*

**The Effects of the Secondary Static Currents in Removing Albumin and Casts from the Urine, with Reports of Cases.**—Boardman Reed speaks of those cases of gastrointestinal disease, in which albumin and casts are found in the urine. These cases have rarely shown any other renal symptoms. About a year ago the writer began the use of static electricity in these cases. The results are most gratifying. The static induced current has a decidedly greater curative power in the kidney affection here described than either the static wave or the high tension faradic currents

**The So-Called Starvation Cure for Bright's Disease and Diabetes.**—Charles T. Beeson reports the case of a man aged forty-four years, who was suffering from headaches and insomnia. In his young manhood, his eyes had failed. A few years ago a trace of sugar was found in his urine, and since then, he has believed that he had kidney disease. He decided to try the starvation cure. This treatment continued for forty days. At the end of this time he was in a very precarious condition. The writer believes that if this man had had either Bright's disease or diabetes, he would be dead to-day. The cessation of the excretory functions in the latter half of the fast, produced an autointoxication which would damage a healthy organ, let alone a degenerated one. The writer believes that eyestrain was the foundation of the sufferings of the patient. If the symptoms from which he suffered were uræmic or diabetic, they grew rapidly worse until food was taken. After his ordinary diet was resumed he returned to a condition of good health.

**The Demonstration of Nucleated Red Blood Corpuscles in Animal Spleens.**—Edward T. Williams states that his personal experiments in this subject have thus far been confined to animal spleens, those of the hog and the ox. His technique is as follows: From a fresh spleen is cut a wedge-shaped piece, about two inches long. Its raw point is drawn across the middle of a clean glass slide, without pressing or squeezing. The object is to make a thin smear. From twelve to twenty smears are made and dried at room heat under cover. The best stain is hæmatoxylin eosin, and the best fixative a dilute, watery solution of sublimate salt. One minute's application of the fixative is sufficient for spleen smears. They are then stained half an hour in watery solution of alum hæmatoxylin, washed, and counterstained from two to three minutes in a three-per-cent. watery eosin. After the proper field is found, a drop of cedar oil is placed on the uncovered slide. It takes great care and patience to discover the erythroblasts. The writer has given two years to this study, and he declares that erythroblasts are a constant anatomic element in the spleens of cattle and swine. Newmann states that he has many times seen these corpuscles in the spleens of human adults.

*The Lancet, November 21, 1903.*

**The Anæmias of Infancy.**—C. Riviere states (1) That anæmia from any cause in infancy, if severe enough, gives rise to the peculiar symptoms grouped under the headings "anæmia splenica infantum" and "anæmia splenica pseudo-leukæmic" of von Jaksch. (2) That consequently these are not specific blood diseases, but owe their peculiarities merely to the "infancy factor" and that they represent merely different stages of the same condition. (3) That the common cause of severe anæmia in infants is gastrointestinal catarrh, leading to the absorption of toxins either from the growth of microorganisms or possibly from the formation of poisonous by-products of digestion. (4) That leukæmia of infants is not a separate disease, but merely a still more advanced stage of this anæmia—that is, that the difference between them is one of degree and not of kind. (5) That leukæmia of adults is a return to the condition of an infantile anæmia, and that, being rare, its causation is probably so narrowed down as to be practically specific.

**A Case of Linseed Poisoning.**—J. O. Hollick records the case of a robust male adult who applied a hot linseed poultice to an inflamed hemorrhoid. Four hours later he began to have unusual sensations in the throat and on the skin; a reddish-purple hue of the latter, deafness, impairment of vision, diarrhœa and vomiting. Two hours after the commencement of symptoms he was first seen by the author and was in a state of collapse with quick and feeble pulse, a feeling of nausea, and cyanosed face and extremities. His respiration was quiet and the diarrhœa had ceased, but he had a marked condition of cutis anserina. He lay curled up on his side in bed and was very prostrate; he at once told me that he had been poisoned by linseed as recognized from his previous experiences. He was given an ounce of brandy in hot water, and hot bottles were placed to his feet and body; he passed a good night and on the next day was in normal health again. According to the author, the symptoms were due to one of the elements of the oil of linseed, viz., glyceride of linoleic acid. The patient had been previously twice poisoned by eating a few linseeds.

**Unusual Case of Intestinal Obstruction.**—The patient of D. Macartney was a woman of forty-two years and subject to obstinate constipation. She was suddenly seized with abdominal colicky pains, worse near the umbilicus and the left side. Later fecal vomiting appeared with the usual condition of collapse. Examination of the abdomen externally and per rectum revealed no cause for the obstruction. Abdominal incision was made and a few inches above the ileo-cæcal valve there was found a cylindrical plug nearly three inches in length, the upper part being soft and the latter made up of hard irregular bodies. By manipulation the various masses were gradually moved on into the large bowel. The wound was closed in the usual way. An enema was given in due time, and in the excreta were found a dozen small chicken bones and a large number of raisin skins. These peculiar substances were injected, the patient acknowledged, on the second day before the attack, she and her husband having eaten a chicken, feet and all, and a currant-bun.

**Guaiacol Carbonate in the Treatment of Measles.**—This remedy is extolled by D. M. Paton, who finds the remedy a specific in bronchial catarrh with fever. The latter is reduced promptly. The remedy has no effect on the measles itself. Bismuth added to the remedy will relieve any tendency to vomit; the same holds true of Dover's powder with reference to diarrhœa. The treatment is begun when the diagnosis is made, and continued in full doses till the temperature has fallen to normal, a reduced quantity being given for two days longer to make sure of the result. The dose is calculated at one drachm per diem in powders of ten grains every three hours for adults, and children in proportion. The powder is readily taken by children, and all the more so if an equal amount of powdered sugar is added. No unfavorable symptoms have ever been seen during its administration which could in the slightest degree be attributed to the treatment; in no case has it failed to abort the bronchial catarrh, and there have been no deaths.

*British Medical Journal, November 21, 1903.*

**A Preliminary Report on the Treatment of Advanced Pulmonary Tuberculosis by Intravenous Injections of Iodoform.**—Thomas W. Dewar declares that all the patients treated had tubercle bacilli, cocci, and elastic tissue in the sputum, and in all both lungs were affected. In every case there has been a great and sometimes rapid improvement in the physical signs; temperatures have become normal, weight and vigor increased, and expectoration and organisms diminished. This has taken place in patients with cavity formation, whose cases have been considered hopeless. The ethereal solution of this drug is used. The solution is not quite saturated. It must be introduced very slowly. This method promises excellent results.

**Two Cases Illustrating the Fallacy of Certain Physical Signs in Diagnosing Acute Perforated Gastric Ulcer.**—W. Harland Peake reports these cases. In both cases there was pain of a paroxysmal character. There was early vomiting in the first case. The presence or absence of liver dulness is an uncertain sign. In the first case the liver dulness was present, in the second case it was absent. The second case seemed very like a perforated gastric ulcer with resulting peritonitis. The writer believes it to have been an example of dilated stomach, due probably to a

gastric ulcer causing reflex spasm of the pylorus, but not necessarily at or near that orifice. The presence of spots tender to deep pressure was suggestive of that condition, in spite of the fact that salt water caused no smarting. The acute pain was probably due to gastralgia.

**Case of Aortic Disease with Unusual Course.**—H. E. Bruce-Porter sums up the points in this case as follows: There was an acute aortitis which caused puckering of the orifice and a regurgitant murmur, the heart for two years compensated by enlargement of the left ventricle; under the strain of service in India the compensation failed somewhat rapidly, and dilatation set in; this caused leakage at the initial orifice and the usual back pressure began to tell. For over six months the patient lived in a state of comparative comfort, with the mitral lesion, while there was albumin in the urine. At one time, as much as 1½ gr. morphine was given in the twenty-four hours with no untoward results. Toward the end the quantity of this drug was reduced. During the last five months there were not more than three attacks of angina.

*Deutsche medicinische Wochenschrift, November* 12, 1903.

**Substitution of an Ivory Rod for the Entire Diaphysis of the Radius.**—Vogel performed a sequestrotomy of the entire radial diaphysis on a girl of eight years. In spite of all efforts at correction the hand kept inclining toward the unsupported radial side; a subluxation of the corpus taking place. In order to prevent this from progressing an ivory rod was placed in the defect, its pointed ends being stuck into the two epiphyses. The soft parts were sutured and healed promptly. After three weeks, active and passive movements were begun, and one year after operation function was still practically normal, and *x*-ray pictures showed that the ivory radius was undisturbed and that a new growth of bone was taking place from the epiphyses to keep pace with the lengthening of the ulna.

**The Etiology of Dysentery.**—Jürgens believes that the efforts to reduce the etiology of epidemic dysentery to a single bacterium, such as the Kruse bacillus, are not likely to be successful, and that different organisms will be found in different epidemics and in different parts of the world. In a garrison epidemic lately observed by him twenty-six cases of true dysentery occurred and a careful bacteriological study was made. In none of them was the Kruse bacillus or the entamœba found, but from the fæces of eighteen patients a bacillus could be cultivated which was similar to the Kruse bacillus, but different from it in its agglutinating properties, as well as in the fact that it forms acid on mannit-agar. This organism appears to be identical to Flexner's bacillus, or at least very closely related to it. Several days after the onset of the disease it gave agglutinations in dilutions of from one to one hundred to one to five hundred and even higher, while no agglutination whatever occurred with the Kruse bacillus. The author concludes that though dysentery may represent a clinical entity, it undoubtedly has numerous causative agents.

*Berliner klinische Wochenschrift, November* 9, 1903.

**Lime Dust Inhalation and Pulmonary Tuberculosis.**—Reckzeh says that the statistics in lime-producing districts show that pulmonary tuberculosis is rare, and that sometimes when present its course is favorably affected. Various authors ascribe this beneficial effect to different features attending the occupation of lime burning. Such are, an effect of the inhaled lime dust in facilitating calcification of suppurating foci, the dryness of the inhaled air, and the deeper respiration it makes necessary, the warmth of the inspired air which contains no tubercle bacilli and the more active metabolism it causes. In order to determine the effect of the lime dust suspended in the air the author caused eight tuberculous patients to inhale air charged with the dust by striking suspended bags filled with powdered lime. At first the inhalations were carried on for five minutes daily, but the time and frequency were gradually increased. The results were without encouragement, no improvement in the pulmonary condition was noted, while there were marked undesirable secondary effects, such as headache, loss of appetite, and nausea.

**A Case of Multiple Cranial Nerve Palsy with Involvement of the Eighth Nerve.**—Aronsohn was consulted by a man who, after exposure to cold, developed pain and swelling of the left side of the face. These symptoms subsided in a few days, but in the course of two weeks the left side of the face became drawn, speech grew difficult as well as mastication on the left side. Headache and vertigo set in, and later tinnitus and deafness in the left ear came on. The origin of this left-sided palsy, including the facial, trigeminal, and auditory nerves was at first assumed to be the result of a multiple neuritis due to the exposure, as brain tumor, etc., could be excluded. Iodide of potassium was given to correct the vertigo, but the promptness with which all the symptoms, except the deafness, subsided under its use made it probable that some syphilitic disease of the base of the brain was at the root of the trouble. The same injury therefore damages the eighth nerve to a greater degree than its fellows, and its function once lost the palsy remains permanent after even only a few weeks have elapsed.

*Münchener medicinische Wochenschrift, November* 10, 1903.

**A Case of Hyperidrosis Universalis.**—Müller reports the case of a hospital nurse of twenty who for nine months had been suffering from a general hyperidrosis which was not amenable to any form of treatment. The condition was so severe as to require a change of the patient's linen about twenty times a day and to occasion a severe eczema. She had lost about forty pounds in weight and had a constant subfebrile temperature; pulse, 108-120; respirations, 24. Menstruation had ceased since the sickness began, but on one occasion when there was a slight flow the sweating was much diminished while the period lasted. After six months, with several exacerbations and remissions, the patient died. The author says that the rapid pulse and respiration, together with the sweating, gave the picture of a person doing violent muscular work, and he regards the condition as one of overactive metabolism. The underlying cause he believes to have been neurasthenia due to overwork, though he admits the possibility of some cerebellar or medullar lesion having been present and causing stimulation of the sweat centers, such conditions having been present in some of the few reported cases.

**Incipient Tabes and Cerebrospinal Syphilis.**—Schittenhelm calls attention to the fact that while formerly the lost knee-jerk was considered the most useful symptom in the early diagnosis of tabes, at the present time authorities are giving more importance to the Argyll-Robertson pupil. Owing to the difficulty of securing autopsies in the early stages of the disease, pathological reports are still scanty, but two cases are on record in which the lost pupillary reflex was the only symptom of a tabes subsequently proven to have been present; himself contributes a third. The patient died of a rapidly progressive pulmonary tuberculosis, and typical degenerative changes were found in the posterior columns of the cord beginning in the upper dorsal segments. That the tuberculous lesion could have had any connection with the ascending degeneration is impossible, owing to the greater age of the latter process shown by the extensive connective tissue growth, and the author considers that loss of the light reflex may be the earliest and *only* symptom of tabes, conditions likely to complicate the diagnosis are progressive paralysis and cerebrospinal syphilis. He describes an instance of the latter affection in which incipient cervical tabes was simulated, but which later developed symptoms pointing toward progressive paralysis, and finally cleared up completely under mixed treatment, showing it to have been cerebrospinal syphilis.

**Remarkable Complications of Gastric Carcinoma.**—Kaufmann describes two cases of this disease accompanied by unusual complications. The first is that of a man of thirty-four years who had had a posterior gastroenterostomy done on account of an inoperable carcinomatous stenosis of the pylorus. The operation was followed by great improvement, but after a few weeks symptoms of aggravated motor insufficiency developed, together with evidence of a stenosis of the transverse colon. The tympanitic distention limited to the right side of the abdomen increased in severity and was accompanied by intense colicky pains. Constipation was succeeded by bloody diarrhœa, and death ensued with the picture of perforative peritonitis. The autopsy showed a massive growth about the pylorus with involvement of the gastrocolic omentum, causing it to contract and obstruct the lumen of the colon. Secondarily to the fecal stagnation in the distended gut, numerous ulcerations of the mucous membrane had developed and extended even into the lower part of the ileum. Two of the latter had perforated and given rise to the fatal peritonitis. In the other case a growth at the cardia extensive enough to cause almost complete stenosis was accompanied by great motor insufficiency. At operation it was discovered that glandular metastases were obstructing the pylorus mechanically. An anterior gastroenterostomy with gastrostomy was done, but death followed on the ninth day, owing to hemorrhage from the tumor.

*The American Journal of the Medical Sciences, Nov.*, 1903.

**Hypertrophic Tuberculosis of the Larynx.**—Clement F. Theisen concludes that: (1) Hypertrophic or hyperplastic tuberculosis of the larynx must be considered a distinct and unusual form of the disease. (2) As a rule,

there is no ulceration, but there may be some late in the course of the disease. (3) Ulceration may be present at the same time as the hyperplasia of the tissues in some part of the larynx, but the characteristic circumscribed hypertrophics and tumor formations do not break down. (4) It is practically always secondary to the pulmonary involvement, but there appears to be some evidence in support of the statement that particularly this form of tuberculosis may at times be primary.

**Tuberculosis of the Tonsils, and the Tonsils as a Portal of Tuberculous Infection.**—Henry Koplik states that the tonsil is the seat of primary tuberculous infection, though rarely, as compared to the pyogenic forms of infection. The tuberculous tissue is found in the form of giant cells and tuberculous nodules; cheesy degeneration in the tonsil is not common; if the tubercle bacilli are abundant it is exceptional; tuberculous tonsillar ulcers are rare; as a rule, the lymph nodes leading from the tonsil are affected. Some of these tonsillar affections have been preceded by a simple catarrhal or diphtheritic inflammation of the organ. Tonsillar tuberculosis may be the source of a general tuberculosis of the body. As far as the cervical lymph nodes are concerned, when found, the seat of isolated tuberculous infection, of a primary nature, it can be justly claimed that such infection has proceeded from the tonsil.

**The Etiology of Nasal Polypi, with Especial Reference to Their Association with Other Pathological Conditions.**—Francis R. Packard discusses the frequency of these growths. They also ocur very often after apparently complete extirpation. He believes that recurrence is most frequent when polypi are the result of caries or necrosis of the ethmoid bone, and they can only be finally extirpated by the removal of the diseased bony tissue. The writer then speaks of the last six cases of intranasal polypi which have come under his care in private practice. He was able to remove dead bone from the middle turbinate region in two of the cases. In all six cases he is convinced that the polypi were present as a result of the disease of the bone; that the recurrence in four was due to failure to recognize their etiology and remove the cause, and that they would have recurred again in all six cases had the necrosed bone not been found and removed. The writer believes that nasal polypi are symptoms of underlying conditions.

**Spondylitis Deformans.**—John Ruhrâh speaks of the symptom-complex of this disease in the early stage as being made up of four parts: (1) Pain; (2) limitation of motion; (3) muscular contractions; (4) referred pains due to pressure on the nerve roots. Later in the disease the spine is as if the vertebræ had been soldered together. This condition may be complete or limited. There is present a certain amount of deformity of the spine as well as the stiffness. The upper part of the backbone curves forward. Ankylosis of the shoulder and hip-joints is a second marked feature of the disease. The disease is undoubtedly more common than has been generally supposed. As to prognosis, Goldthwait believes that with an early diagnosis and proper treatment it is better than was formerly supposed. The danger to life itself is trifling. The general condition of the patient should receive attention. The tendency to constipation should be corrected. Good food, plenty of fresh air, and tonics should be advised. Local warmth is agreeable to these patients, and a thick layer of cotton may be applied next to the skin. Forced movements are not to be used.

**The Fermentation Theory of Infection and Immunity.**—J. W. McLaughlin holds that infection and fermentation are analogous processes or phases of the same process, and that both are due to the operation of the same physical and chemical laws. The active, obvious cause in both processes is a microorganism or an ensyme, which is selective in its activity, in that a definite relation in molecular structure must exist between the acting substance and the substance acted upon before infection or fermentation can take place. The resulting products of the process, whether they be infectious or fermentative, are antibodies which tend to inhibit or to arrest the process of which they are the products. The writer believes that the manifestation of specific energy by ferment and pathogenic cells, which varies with the species and variety of the microorganism, is a result of specific differences in molecular structure of the cells of the different classes. The specific energy of the living ferment or pathogenic cell is capable of converting substances into ferment or pathogenic products whose molecular structure does not deviate too far from the molecular structure of the cell. The forces involved in the fermentation theory of immunity are those operating in nature within and without the living organism. They are the forces which constitute motion in matter. It is seen that the fermentation theory, in many respects, runs parallel to the side-chain theory of immunity. The writer finally calls attention to what may be regarded as weak places in the fermentation theory.

*French and Italian Journals.*

**Hysterical Aphasia.**—M. Raymond reports the case of a young woman, who, after a severe mental shock, became paralyzed on the right side, and was unable to speak. She remained in bed for a month, recovered speech in a fortnight, and in a few months walked normally. Slight cerebral hemorrhage might have been supposed to be present, except that the face was unaffected, the shoulder showed no drooping, the reflexes were normal, and when rising and sitting up from a recumbent position, both legs were raised equally. Moreover there were other signs of hysteria.—*Journal des Praticiens*, November 11, 1903.

**Predisposing Causes of Surgical Tuberculosis in the Italian Army.**—Antonio Perassi considers the following conditions to be the expression of an unstable equilibrium of health, favorable to the invasion and dissemination of the Koch bacillus: (1) Organic weakness, connected with development. (2) Previous tuberculous infection, which has remained latent in the system. (3) A sort of acquired predisposition, depending on imperfect hygiene, or following violent lesions in which the non-success of treatment is in the early stages considered as a cause, and later as an effect of the tuberculous localization.—*Giornale Medico del Regio Esercito*, October 31, 1903.

**A New Method of Administering Oils.**—H. Boissel remarks that the facility with which castor oil can be given in frothing beer is well known to all practitioners. It is, however, not always easy nor advisable to give beer, therefore he has devised a frothing mixture which serves the same purpose. It is in the form of a powder, composed of gum arabic, liquorice, and lactose flavored with vanilla. A pinch of this powder, shaken with a little water, produces a very persistent froth, in which any oily substance as cod-liver oil, castor oil, iodized or phosphorated oil can be given, as well as medicines lighter than the mixture, such as the salicylate of methyl, essence of santal, etc., can be given, without the slightest unpleasant taste.—*Gazette Hebdomadaire des Sciences Médicales*, November 8, 1903.

**Chloride of Lime in Puerperal Infection.**—A. Ethier reports the successful use of this substance in a uterine douche in a case of puerperal infection. One hundred grams of the chloride of lime were dissolved in 1,200 grams of boiled water, and filtered. A glassful of the fluid was mixed in nine glassfuls of hot boiled water, and injected very slowly. He has also used it in cases of simple metritis with a viscid glairy discharge. It liquifies the viscosities, is non-irritating, causes no pain, and is not poisonous like bichloride. In cases of ulcerated and inoperable neoplasms of the vagina with fetid discharge, it causes rapid deodorization. It must not be used in a vagina which has recently been treated by the carbide of calcium without carefully removing all traces of this salt, otherwise the two substances will ignite and explode. Calcium chloride is also indicated in suppurating wounds with no tendency to heal, and in abscess of the breast.—*La Revue Médicale du Canada*, November 12, 1903.

**Seasickness.**—M. Pénaud holds that this affection is a true morbid entity with definite symptoms, the primordial cause being the motions of the ship, accompanied by numerous adjuvant causes. It is a disease of equilibrium, affected first in its orientation, and then accompanied by a complication of symptoms due to a veritable discharge from the centers of equilibrium toward other centers. General kinæsthesia vitiated in its muscular and tactile sensations, plays its part, the rôle of the displacement of the abdominal organs being a prominent one. The other paths of orientation (labryinthine, optical) may also serve as a starting point for the trouble. Faulty equilibration and naupathia are closely connected by their causes and symptoms. The centers of equilibration may in time become accustomed to the motions of the vessel. Treatment should be preventive and curative, etiologic and pathogenic. Etiologic forms of treatment are aëration, ventilation, superoxygenation, disinfection, deodorization, autosuggestion and suggestion medicines. Pathogenic treatment consists in the application of bandages, calagn or wedging of the patient with Auffret's apparatus, the wearing of smoked or red glasses, the fixation of an immovable point on the horizon, closing the eyes, the arranging of a special infirmary in the middle of the ship for seasick patients equipped with all the necessary things for resisting the affection.—*Journal du Mal de Mer*, May–July, 1903.

# Book Reviews.

THE MEDICAL RECORD VISITING LIST, or Physicians' Diary for 1904. New Revised Edition. New York: William Wood & Company, 1904.

THIS favorite pocket record of visits made and to be made, of consultations held, and of surgical and obstetric operations performed makes its usual timely appearance. In addition to the tables of doses of drugs, antidotes, modes of artificial respiration, and other memoranda liable to be needed in emergencies, we find some brief suggestions regarding the writing of wills and a conveniently arranged obstetric calendar for determining the probable date of the termination of pregnancy. The book is well made with tough paper which takes ink readily without spreading, while yet of a sufficiently rough surface for lead-pencil use, and excellently bound in flexible morocco covers.

THE PRACTICE OF OBSTETRICS. By J. CLIFTON EDGAR, M.D., Professor of Obstetrics in the Cornell University Medical College; Attending Physician to the New York Maternity Hospital. Philadelphia: P Blakiston's Son & Co., 1903.

AT first glance, this large and handsomely bound volume, of over 1,100 pages and 1,200 illustrations, suggests a medical dictionary, but despite its apparent voluminousness no space is wasted in theorizing; it is everywhere practical and helpful. The author's long experience as a teacher is evidenced by his painstaking attention to the little details which cause the novice so much trouble, and which are too often passed over in textbooks as unworthy of notice. For example, the toilet of the finger nails is described with the greatest minuteness, and pictures are inserted to show just how the orange stick and the edge of the towel should be used, and how the nails should be groomed.

The book is divided into ten parts, each of which is subdivided into sections, and a table of contents precedes each part and section. Pelvimetry and cephalometry are very properly placed under the head of the examination of pregnancy, and are here considered with all the fulness which their importance demands. The sections on deformities and monstrosities of the fœtus, and on antenatal pathology are very full, and the mechanism of labor is clearly described by a new method. Under obstetric surgery a description is given of a simple operation but rarely mentioned in textbooks, viz., cleidotomy, or division of both clavicles. It has proved very useful in cases of contracted pelvis, after perforation and extraction of the fetal head, in which the shoulders offer obstruction. The appendix contains an interesting description of methods of keeping obstetric histories both in private and institutional practice. Last, but not least, there is an index which cannot fail to evoke the gratitude of the student, for it is almost a book in itself.

INTERNATIONAL CLINICS: A QUARTERLY OF ILLUSTRATED CLINICAL LECTURES AND ESPECIALLY PREPARED ORIGINAL ARTICLES. Edited by A. O. J. KELLY, A.M., M.D. Vol. III. Thirteenth series. Philadelphia: J. B. Lippincott Co. 1903.

THE scientific menu for this term includes Diseases of the Gall-bladder and Gall-ducts, by John H. Musser; Diagnosis of Gallstones, by R. D. Rudolph; Cholelithiasis, by C. G. Stockton; Biliary Cirrhosis, by F. P. Weber; Surgical Intervention in Cholelithiasis, by F. Lejars; and Surgical and Postoperative Treatment of Chronic Gallstone Disease, by John B. Deaver. The therapeutic section contains many good short articles on both surgical and medical topics. The general tone and scope of the work is keeping well up to the standard. There is an excellent colored frontispiece illustrating different forms of malarial parasites as described in the article on malarial infections, by Charles F. Craig. There are papers of interest also on anæsthesia, leukæmia, etc.

AN ATLAS OF HUMAN ANATOMY FOR STUDENTS AND PHYSICIANS. By CARL TOLDT, M.D., Professor of Anatomy in the University of Vienna, assisted by ALOIS DELLA ROSA, M.D. Translated from the Third German Edition and Adapted to English and American and International Terminology, by M. EDEN PAUL, M.D., Brux, M.R.C.S., L.R.C.P. First Section: A, The Regions of the Human Body; B, Osteology. New York: Rebman Company, 1903.

THIS excellent atlas has been a favorite of the German profession and of a few anatomists and surgeons in this country for a number of years, but to the majority of American surgeons it is practically unknown. The latter are to be congratulated on having the work now placed within their reach. An atlas cannot, of course, take the place of a treatise on anatomy, such as Gray's or Cunningham's, for students' use, but as a work of reference it is often more convenient than a textbook, and to the student also it is of service as a means of reviewing and fixing in his memory the knowledge he has gained by practical dissection. For these purposes Toldt's Atlas is not surpassed, so far as we are aware, if, indeed, equalled by any work now published in any language.

The work is to be completed in six parts, of which this is the first. It is devoted chiefly to osteology and contains 377 figures illustrating fully the skeleton and all its component bones, together with the architecture of the osseous structures. The names of all the bones and their parts are given in English, or what passes for English in anatomical nomenclature, and Latin. A very satisfactory index completes the volume.

DISEASES OF THE URINARY ORGANS, INCLUDING DIABETES MELLITUS AND INSIPIDUS. By CLIFFORD MITCHELL, A.B., M.D., Professor of Renal Diseases in the Chicago Homœopathic Medical College, Urologist to the Chicago Laboratory for Clinical Diagnosis. Philadelphia: Boericke & Tafel, 1903.

THE author believes that the general practitioner of today must be a specialist in all branches, and, with this view, has prepared a special work which, when digested, will fit the digester for doing as well by his patients as a real specialist could. The surgical side of treating kidneys, bladder, prostate, etc., has been given prominence, and the strictly medical practitioner has no excuse for not knowing that in conditions usually considered strictly medical the knife may, at times, be applied to relieve painful conditions and even to save life.

LES ACTUALITÉS MÉDICALES; LES MÉDICATIONS RECONSTITUANTES, LA MÉDICATION PHOSPHORÉE, GLYCEROPHOSPHATES, LÉCITHINES, NUCLÉINES. PAR HENRI LABBÉ, Chef de Laboratoire a la Faculté de Médecine de Paris. Paris: J. B. Baillière et Fils, 1904.

THIS is a little bound volume of less than a hundred pages. That the proper manner of giving phosphorus under its various forms is a question of decided importance goes without saying. The chemical features of the existence of phosphorus in our tissues and the possibility of adding to and detracting from the same open up fields of inquiry of decided interest. Modern injection methods and the extended use of various glycerophosphates makes the work of interest to most practitioners.

DISEASES OF THE SKIN: AN OUTLINE OF THE PRINCIPLES AND PRACTICE OF DERMATOLOGY. By MALCOLM MORRIS, Consulting Surgeon to the Skin Department, St. Mary's Hospital, London; Corresponding Member of the K. K. Gesellschaft der Aertze in Wien; Honorary Member of the Wiener Dermatologische Gesellschaft and of the Société Française de Dermatologie. New Edition. Chicago: W. T. Keener & Co., 1903.

Dr. MORRIS' original work had many good features. It was small, concise, and to the point, written with the confidence of one who knows. The revised edition, out about five years ago, has been some time exhausted. In bringing out this new edition, the manual form has been preserved, and additions have been made without increasing much the size.

Though radiotherapy is touched upon here and there, we are surprised not to find more written upon it, knowing from his other publications how much attention the author has given to these newer methods.

Many of the illustrations are wholly inadequate and disproportionate to the worth of the text. In regard to the contagious nature of molluscum contagiosum, the author is strangely reserved, although this seems no longer to be an open question. He is mistaken in his claim that it never occurs upon the palms or soles, hence this cannot be used as an argument in favor of its being of sebaceous glandular origin. While the work is not perfect, it has many points in its favor.

CLINICAL PATHOLOGY OF THE BLOOD. A Treatise on the General Principles and Special Applications of Hematology. By JAMES EWING, A.M., M.D., Professor of Pathology in Cornell University Medical College, New York City. Second Edition. Revised and Enlarged. New York and Philadelphia: Lea Brothers & Co., 1903.

AN index of the amount of work that is being done in hematology is furnished by the statement of the author of this book, that he has added the titles of about four hundred journal articles and monographs which have appeared in the two years since the first edition of his work was published. He has incorporated what was new in these articles in the present edition, the additions and changes being chiefly on technics, the serum test for blood, cryoscopy, and the morphology of blood cells. Ehrlich's theory of immunity is also described briefly. High rank was accorded to Dr. Ewing's book immediately upon the appearance of the first edition, and the sustained excellence of the second edition shows that the favorable judgment of the early critics of the work was not at fault.

# Society Reports.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, Held November 5, 1903.*

ANDREW H. SMITH, M.D., PRESIDENT.

**Eye Lesions Occurring in Diseases of the Heart, Blood Vessels, and Kidneys.**—Dr. CHARLES STEDMAN BULL read this paper (see page 881).

Dr. FRANCIS P. KINNICUTT opened the discussion (see page 884).

Dr. WARD A. HOLDEN spoke of the pathology of albuminuric retinitis. He divided the alterations in the retina into: (1) The diffuse œdema of the retina and optic nerve; (2) larger hemorrhages and white patches situated a short distance from the disk in the superficial layers of the retina, and (3) small hemorrhages and white patches arranged in a radiating manner around the macula. When the œdema affected the optic nerve, there might be considerable constriction of the vessels. He did not think one could speak of an actual retinitis in many cases; it was usually simply an œdema. The hemorrhages and white patches which appeared at some distance from the disk lay in the superficial layers of the retina and spread out in the direction of the nerve fibers. These began almost invariably as hemorrhages by diapedesis, the red blood corpuscles being poured out by the larger veins. After a time these red corpuscles broke down and were taken up by fatty granular cells, thus producing some of the white patches. Capillary hemorrhages in the macular region were the rule, because here there were no large vessels. When the capillaries became altered small hemorrhages formed, usually in the outer reticular layer. These red spots became very quickly transformed into white ones. These pictures of hemorrhages were in no sense characteristic, because they occurred in a great variety of toxic conditions of the blood, and even might be present as a result of simple arteriosclerosis. In the kidney affections producing albuminuric retinitis there was a condition of anæmia associated with a degenerated condition of the blood vessels and an increased arterial tension.

Dr. EMIL GRUENING said that he had never seen an arterial hemorrhage in the eye; the hemorrhages observed in the eye were, in his opinion, almost without exception, venous.

Dr. J. W. BRANNAN recalled two recent cases, both of women of about forty-five years of age, who had borne children. The first patient was known to have chronic diffuse nephritis, with albumin and casts more or less constantly pressure in the urine. The heart was rather weak. In February, 1902, when recovering from a severe attack of sick headache, she was found unconscious in the bath room. He found her suffering from left hemiplegia. From this she recovered fairly well. There was some slight impairment of vision, but no ophthalmoscopic examination was made. She lived about one year. The case was cited because of the comparative absence of eye symptoms notwithstanding the persistence of a marked albuminuria. The second patient had also been under his care for some years. In September, 1902, there was no albuminuria, but she suffered from chronic indigestion prior to the attack of apoplexy. When seen by him there was some impairment of the right side of the body and left side of the face. There was marked paralysis of the ocular muscles and of the face. She died about one year later. He had learned that she never fully recovered the use of the eye muscles, and that an ophthalmoscopic examination, made during the summer, was negative. Although no albumin had been found prior to the attack of hemiplegia, a large quantity of albumin was found in the urine just after the attack. A few casts were also present. Repeated subsequent examinations of the urine failed to show either albumin or casts. He had had the same experience in connection with other cases of apoplexy.

Dr. THOMAS R. POOLEY commented upon the paucity of our knowledge of this subject despite the voluminous literature. He said that some years ago he had found it exceedingly difficult to observe pulsation of the vessels of the eye in a series of cases of heart disease that he had specially studied with regard to this phenomenon. For this reason the ophthalmologist should be very circumspect in speaking on this point. He had long had grave doubts as to whether the picture said to indicate embolism of the central retinal artery was really due to this cause, and he believed Dr. Bull also entertained such a doubt. In very few of the autopsies reported on cases of embolism had the possibility of other causes been eliminated. In nearly all the carefully observed cases a thrombosis had also been found. It was very difficult for him to diagnosticate disease of the blood-vessels dependent entirely upon senile changes. With the ophthalmoscope one could only detect senile arteriosclerosis by observing a diminution in the size of the blood column, and when such a picture was observed one should be careful to exclude other conditions, such as syphilis, before putting the case down as senile. Typical cases of Bright's neuroretinitis were, in his opinion, few and far between. In many cases of granular degeneration of the kidneys he had found only petechial hemorrhages. The speaker said that he had been one of the first in this country to write upon the subject of the induction of premature labor in cases of albuminuric retinitis. This was about twenty years ago. He was strongly impressed with the necessity of inducing premature labor in cases of Bright's neuroretinitis, and these were the only cases that made the exceptions in the bad prognosis. If labor were promptly induced before the ocular disease had gone too far, restoration of sight might be expected. Dr. Bull's report of 103 cases was one of the most complete and classical studies in the whole literature of this subject. Dr. Pooley referred to the occurrence of hemorrhages in the eye between the retina and the vitreous, and also to the fact that many persons who had had subconjunctival hemorrhages subsequently died of cerebral hemorrhage.

Dr. H. KNAPP said that there were not only hemorrhages of the central retinal artery, but of its branches. Several such cases were described. With regard to choked disk he said it occurred principally in connection with disturbance of the intracranial circulation. It was true that it often occurred with tumor of the brain, but it was also present in connection with certain nervous diseases and with Bright's disease.

**Medical Superintendent for the State Tuberculosis Hospital.**—Dr. ALFRED MEYER announced that a civil-service examination would soon be held for the selection of a medical superintendent for the new State Hospital for Tuberculosis at Raybrook. The salary would be $3,500 besides maintenance, and the superintendent would have a handsome suite of rooms at his disposal. Applicants for the position must have had at least six years' actual practice of medicine, and have spent at least one year in an institution for consumptives. This special experience would count 50 per cent. on the examinaion. Further details could be obtained by applying to the Civil Service Board, Albany.

---

*Anniversary Meeting, Held November 19, 1903.*

ANDREW H. SMITH, M.D., PRESIDENT.

**Anniversary Address: "The Economic Value of Medical Science."**—Dr. W. GILMAN THOMPSON delivered this address. He said that unquestionably the most far-reaching economic benefit in recent years arising from medical science was that the public was being taught not to flee from epidemics and pandemics, but to stay and control them. The shotgun quarantine was rapidly becoming a thing of the past. In 1853 the mortality from yellow fever in the districts in which it prevailed was as

great as from the plague in other parts of the world. To-day, instead of paralyzing the business of whole communities, the mosquito was killed, the rat destroyed, and the drinking water boiled. It was a hope, fully capable of realization, that the plague would be restricted before long to its home, the valley of the Euphrates. Malaria was now to be recognized as a preventable disease. It was easy to estimate the cost of this disease in any given locality. The mean annual mortality from malaria in Italy was estimated at 15,000, and there were about two million cases annually.

In the early days of the past century a large proportion of persons above twenty years of age were deeply pitted by smallpox, yet it was very rare to meet such a face to-day. Within the past decade in the State of Massachusetts alone the mortality from tuberculosis had been reduced exactly one-half. Typhoid fever and epidemic dysentery were now known to be completely preventable, and it was no fault of the science of medicine if the public did not adopt the measures necessary for their prevention. Not the least among the important aspects of medical science was the amount of capital invested in its colleges, research laboratories, training schools, and hospitals. The 125 medical schools of this country possessed property valued at over eighteen million dollars, and endowment funds exceeding eight million dollars. It was interesting to note that the schools of theology, while possessing nearly the same amount of property, enjoyed nearly five times as much in endowment. In the United States the twenty-nine schools for the feeble-minded represented a property value of more than three and a half millions, and the thirty-seven schools for the blind, six millions and a quarter dollars' worth of property. It was a conservative estimate that in this country alone there were three or four hundred million dollars' worth of property which had arisen mainly during the past two generations, largely from the coöperation of medical knowledge with humanitarian aims. In the care of criminals and of the insane great advances had been made, largely through the enlightenment brought about by medical science. It had been ascertained that 90 per cent. of the cases of insanity had their origin in errors of the body of the nature of chronic disease. It had been shown especially in this city that the place to check the spread of many of the contagious diseases was at the entrance to the public schools. The teachers of these schools should be masters of physiology and hygiene. In the hygienic problems of our own city we had much to learn and much to apply. The pupil, the public, was always late at school, if not an actual truant. The questions of proper ventilation of our tunnels and cars, the limitation of the building of skyscrapers, the avoidance of spreading clouds of dirt through the streets and in the eyes of pedestrians when removing ashes, were all matters which concerned the public at the present time. The public should insist that the members of health boards should have scientific training, capacity, and force. It had long been recognized that in all protracted military campaigns more men die from disease than from actual warfare. In camp life, at least, epidemics were preventable. The mortality from disease in early campaigns had been truly horrible. Of even greater importance in an active military campaign was the health or efficiency of an army, and recent years had shown a most gratifying improvement in this respect. The various methods of food preservation, although in some instances antedating bacteriology, were all expanded by it, and their efficiency had been greatly enhanced by its aid. Bacteriology, fundamentally a department of medical science, had been expanded to proportions which it was difficult for the mind to appreciate. The science of meteorology in this country had its origin in careful systematic observations of climate by the medical department of the army. In 1774 American medical literature comprised one new book and three reprints; to-day the output in medical science in this country was, on an average, one new book for each working day in the year, to say nothing of the many journals. The thirty years of bacteriology, in all its applications, had done more for mankind than all the medical researches that had preceded it.

### SECTION ON OBSTETRICS AND GYNECOLOGY.

*Stated Meeting, Held October 22, 1903.*

L. J. LADINSKI, M.D., CHAIRMAN.

**Tubo-ovarian Abscess; Extensive Pelvic Peritonitis, Probably the Result of Typhoid Fever; Abdominal Panhysterectomy.**—Dr. H. J. BOLDT reported this case, and presented the specimen. He said that it had been known for many years that infectious diseases had a detrimental effect on the pelvic organs, but that typhoid fever should have such a remarkable influence as in this particular case seemed inexplicable. However, the history pointed so directly to this being the case, that no other interpretation appeared to be warranted. The woman, D. T., had been sent to his service from Connecticut with the history of having been perfectly well up to an attack of typhoid fever, and of having since then suffered from pelvic pain and obstinate constipation, and at times discharges of pus with the movements of the bowels. Examination revealed an extensive pelvic exudate with the uterus tightly fixed in retroflexion. The adnexa were seemingly embedded in this exudate. The diagnosis from bimanual examination was suppurative salpingitis with the pus cavity probably communicating with the rectum. On opening the abdomen it was found that the diffuseness of intestinal adhesions from the pelvic peritonitis had been underestimated. The pyosalpinx on the left side communicated with the large bowel, and, after separation, the intestinal opening was closed with catgut sutures. The left ovary was not suppurating, but was firmly adherent. The tube was loosened, but the gland was left attached to the pelvic wall by its adhesions. On the right side was a tuboovarian abscess, with much thickening of the parametrium. The abscess ruptured during enucleation. The wound surface being so large, and the bowel having been slightly injured so low down, suture was out of the question, accordingly a pan-hysterectomy was done and the pelvis packed with gauze. The appendix vermiformis was unusually long, probably fully ten inches, and extended upward nearly to the liver. There was considerable inflammatory thickening, and it was adherent throughout. It was removed. It was now the third day since the operation, and the highest temperature had been 98.4°F.

**Unruptured Ectopic Gestation.**—Dr. BOLDT also presented this specimen, which was taken from a woman who had no bloody discharge whatever. A diagnosis of tubal abortion had been made. The case emphasized the fact that one could not distinguish tubal abortion from a slowly produced tubal rupture.

**Dermoid Cysts of Both Ovaries.**—Dr. CHARLES F. ADAMS presented this specimen, which he had removed two or three weeks ago from a single woman, twenty-six years of age, who complained only of some pain in the left iliac region. He said that while these dermoid cysts were frequently met with, it was quite uncommon to find them in both ovaries.

Dr. P. A. HARRIS said regarding Dr. Boldt's specimen that he believed the operator frequently ruptured the fetal membranes during the operation. He had succeeded in securing three such specimens of intact fetal sac. He had never met with pelvic inflammation apparently resulting from the acute infectious diseases.

Dr. J. FINLEY BELL asked Dr. Boldt whether he regarded the salpingitis in the first case as a local typhoid focus, and whether any cultures were made from the pus.

Dr. L. J. LADINSKI said that he had recently seen a woman with a large abscess extending down from the diaphragm almost to the pelvis. She was at the time

in the third week of typhoid fever. On performing laparotomy, it was discovered that the abscess had originated in the gall-bladder, and involved not only the appendix but also the tube and ovary on that side. In this case there was absolutely no question about the infections having spread through the colon to the gall-bladder, appendix, and adnexa. He could not at the moment recall any case of pelvic inflammation which could be attributed to typhoid infection. With regard to the second specimen he would say that if the physician had an opportunity of watching the patient sufficiently long the diagnosis of tubal abortion was possible. Dr. Boldt's case was the first one that had come to his knowledge in which there had not been some bleeding, and it was possible that the history was incorrect.

Dr. BOLDT said that the only reason for believing that the pelvic inflammation was the result of the typhoid fever was that there was nothing in the history pointing to any other infection, and the pelvic symptoms did not develop until she suffered from this disease. The pus had not been examined for typhoid bacilli. So far as the differential diagnosis between tubal abortion and partial tubal rupture was concerned, it was his opinion that it was absolutely impossible to differentiate these conditions. He had watched this patient for two or three days, she was quite intelligent, and a special effort had been made, not only by himself but by several other physicians, to secure a correct history in this case. This ectopic gestation was in the fifth or sixth week.

**Experience with Vaginal Section at St. Joseph's Hospital, Yonkers.**—Dr. HENRY MOFFAT presented this report of the work done in this field by the visiting staff of St. Joseph's Hospital, viz., Drs. Hermance, Warren, Duffy, Mooney, Austin, Foy, and himself (See page 886).

Dr. J. RIDDLE GOFFE said that there was not much to add, as the paper contained a frank statement of the results, both good and bad. The staff were to be congratulated on this series of excellent results, particularly as these men laid no claim to being gynecological surgeons. At one time he had himself thought, as did the reader of the paper, that the longitudinal incision was unnecessary, but when the longitudinal incision was made, the fundus could be brought down into the vagina, allowing of taking up the necessary slack in the round ligaments. He was in the habit of making this incision now for his hysterectomies. It was interesting to note that a uterus prolapsed to the introitus could be held in position, as a result of anterior colpotomy, and the patient afterward give birth to a child with so much comfort. He was particularly pleased to learn of this case because this operation had been accused of causing dystocia. The experience of all surgeons seemed to justify the conclusion that in puerperal septicæmia the less the surgical interference the better for the patient. One should meet indications as they arose, such, for example, as opening up pockets of pus, instead of resorting to a more radical procedure.

Dr. E. M. HERMANCE said that he could substantiate what had been said in the paper with regard to the practical value of this method of dealing with pelvic disease. The first time he had tried the method he had done a posterior section for pyosalpinx, and the results had been so excellent that he had since been a staunch advocate of this mode of treatment. The use of the posterior vaginal incision for the purposes of exploration was most important. A case in point was cited. He believed such satisfactory work as they had done on the tubes and ovaries could not have been accomplished in any other way.

Dr. BOLDT said that in determining upon the route for the operation one should consider the size and distensibility of the vagina. It was his experience that while the pelvic could be made accessible through any vagina, if the latter were rigid it would be necessary to make a longitudinal incision through the vagina. Under such circumstances he preferred to do an abdominal section. Whenever a case was suitable for vaginal section this should be selected, as the patients made a smooth and rapid convalescence. Of the two methods, that by the vaginal route was the more difficult. Some years ago when he was doing more vaginal work than at present, his colleagues had opposed it very strongly, yet these same gentlemen were now ardent advocates of vaginal section while he was disposed to limit it more than formerly.

Dr. P. A. HARRIS said that the advocates of the vaginal route had not assured him that the appendix could be excised by this method, and as one who removed the pus tubes through the suprapubic route he felt interested on this point because every now and then he saw, in connection with these operations, an appendix which should be removed. The value of the cul-de-sac incision could not be overestimated in cases of abscess formation, especially after childbirth and abortion. The abscess usually formed in nine or ten days. He was sure that in many cases of double pyosalpinx complicated by abscess of one ovary, the interests of the patient were best subserved by a simple vaginal incision with evacuation of the abscess, and allowing the patient to recover from the sepsis. Some of these patients would not desire any further treatment. This complete and honest presentation of the subject by the surgical staff of St. Joseph's Hospital made it all the more interesting. Only that very day he had done his one hundred and first operation for vaginal hysterectomy. Of the preceding one hundred operations, death occurred on the twenty-second, twenty-fifth, sixty-fourth, and seventy-fourth operation, the operation being done for a variety of conditions.

Dr. LADINSKI said that while he would admit that the vaginal route was preferable in some instances, his personal preference, in most cases, was for the abdominal route. His reason for this was that his experience up to the present time necessitated this view. With the Trendelenburg position he did not hesitate to attack a large pus cavity connecting with the abdominal cavity, yet such cases could not be properly reached from below. Mention was made of a case in which if the vaginal route had been selected it would have been impossible to avoid cutting into the rectum and bladder, for they were adherent to the abscess wall in such a way that any incision from below would have injured them. The paper was interesting as showing what could be accomplished in this field by general surgeons.

Dr. Moffat, in closing the discussion, said that these cases were not offered as an argument in favor of the vaginal route, but simply to show what they had been able to accomplish by this method; certainly every surgeon should perfect himself in both methods. The point made by Dr. Goffe regarding the longitudinal incision in the vagina was very well taken.

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON MEDICINE.

*Stated Meeting, Held November 17, 1903.*

LEWIS A. CONNER, M.D., CHAIRMAN.

**Mitral Stenosis with Multiple Emboli.**—Dr. A. W. HOLLIS reported this case and exhibited the patient. He said there were at least five definite emboli, and they were of unusual size. The marked constitutional disturbance was good evidence of the size of the renal and splenic emboli. In ordinary health, plugging of the posterior tibial or peroneal artery by an embolus should not give rise to gangrene, but in consideration of the valvular disease of the heart, it was not surprising that gangrene should have occurred in this instance.

Dr. L. A. CONNER thought that these large emboli might possibly have arisen from thrombi behind the stenosed valve, and not from vegetations on the valves. The degree of spasticity present in the patient at the present time did not auger well for further improvement.

**Urostealith Calculi.**—Dr. E. E. SMITH exhibited these calculi. They were composed of fatty matter in crystalline form, and were almost entirely soluble in ether, the composition being about one-third neutral fat and two-thirds free fatty acids. Such calculi had been described as long ago as 1855 by Heller. In the case from which one of the calculi presented had been obtained an operation on the kidney had been required subsequently, and this revealed a similar calculus in the kidney, thus proving conclusively that these calculi might be formed in the body, although several observers in the past had maintained that the fatty matter was introduced from without, and was not formed in the body.

**Some Notes on the Widal Reaction.**—Dr. E. LIBMAN read a paper with this title. He said that experience had shown that if the blood were used immediately after drying, the result was not as good as if it were used some hours later; however, in the summer, if the blood were not used for the test within twenty-four hours, it was not so easy to obtain the Widal reaction. Moreover, the result was not so good if the drop of blood were so large that coagulation occurred before drying. It had been noticed at the laboratory of the Mount Sinai Hospital that each year in the month of October the Widal reaction was obtained much earlier in the disease than at other times, and that this period varied somewhat in the different months. At present he was not prepared to offer an explanation for this curious fact. It had been found very often that the Widal reaction was negative with a dilution of one to fifty, until quite late in the disease, whereas it was positive with a dilution of one to twenty. Still more interesting and curious was the fact that the reaction was occasionally positive with a dilution of one to fifty, and was negative or uncertain with the lower dilution of one to twenty. His own experience proved that the dilution of one in twenty was perfectly reliable, and because of the varying results with different dilutions, it was their practice to use both dilutions in every case. The explanation offered for the occurrence of a positive reaction with a high dilution and of a negative reaction with a lower dilution that it was dependent upon the presence of certain bodies, called proglutinoids; in other words, that certain bodies developed from the agglutination, which could combine with the bacilli, but lost the power of combining with the agglutinin.

**Jaundice and the Widal Reaction.**—The work done in this field by various observers was briefly reviewed by Dr. LIBMAN. He pointed out that a number of the reported cases, claimed to be evidence that the presence of jaundice often led to a positive Widal reaction, were far from being convincing on this point, as no effort had been made by bacteriological examinations to determine whether or not typhoid bacilli were present in the gall-bladder, in the fæces, or in the urine. If such examinations had been made, it would have been possible to exclude typhoid fever. The speaker said that in his own studies he had examined the bile in cases of various diseases. Even with a dilution of one to one he had not obtained any characteristic reaction, although occasionally there had been very slight, though imperfect, clumping. In only four cases had they obtained a positive Widal reaction in the presence of jaundice; in all the others, if there was any clumping present, it was no greater than could be obtained from normal blood. One of the positive cases apparently was one of paracolon infection, but as he was inclined to think there was mixed infection, the result was indecisive. In another one of the positive cases, an operation was done for cholelithiasis, and typhoid bacilli were recovered from the gall-bladder, although there was no history of an attack of typhoid fever, and the patient had suffered from cholelithiasis, according to the history, for thirty years. Another one of the cases proved to be cholecystitis occurring during typhoid, and associated with jaundice. The other positive case was also proved to be one of typhoid infection. It was very probable that the cases of positive Widal reaction reported as occurring in that indefinite disorder called "Weil's disease" were examples of infectious jaundice dependent upon typhoid.

Dr. F. C. WOOD said that in his own work at St. Luke's Hospital serum only was used, and in each case dilutions of one to twenty, one to forty, and one to sixty were employed, with a time limit of one hour. In four cases they had obtained agglutination, and had apparently been able to exclude typhoid.

Dr. LIBMAN said that the combination of jaundice and typhoid was rather rare, and, hence, if Weil's disease were nothing more than a combination of typhoid infection and jaundice, the number of reported cases of this disease would be different. His own opinion was that the term "Weil's disease" included several affections characterized by jaundice.

**The Early Diagnosis, and Some New Points in the Treatment of Pulmonary Tuberculosis.**—Dr. W. FREUDENTHAL read this paper. He said that, having practised laryngology for many years, he had made it a rule to look carefully for tuberculosis in every case of persistent laryngitis, and he had been surprised at times at his ability to detect in this way a pulmonary tuberculosis that had been hitherto unrecognized. He was convinced that a great number of those who suffered from dry atrophic rhinitis fell victims to tuberculosis. In many tuberculous subjects one would find very early a peculiar anæmia of the soft palate, and of a large part of the hard palate, associated with more or less congestion of the adjacent parts. Such individuals were very apt to show the well-known general congestion of the larynx with the characteristic pallor of the epiglottis. Every now and then one met with cases in which all of the usual diagnostic signs failed, and then one should resort to the injection of Koch's tuberculin. He had employed this agent for diagnostic purposes in thirty-one cases, six in private, and the remainder in hospital practise. The initial dose was half to two milligrams. If no reaction occurred, the dose was increased to three or five milligrams, and in rare instances, even up to eight or ten milligrams. The injection was made into the shoulder. In none of the cases did he recall any unpleasant results. Of the thirty-one cases, fourteen reacted after the first injection, twelve after the second, while five did not react at all.

With regard to therapy, he said that he believed the electric light was an important factor in the treatment of pulmonary tuberculosis. He had found that it acted as an anodyne, except in tuberculous laryngitis, that it favored expectoration and exerted a beneficial influence upon metabolism. By the use of the electric light the activity of the skin was greatly increased, and the deeper organs were also stimulated. The greater the proportion of oxygen in the body, the better the effect of the electric light. To secure this advantage he had adopted the old therapeutic resource of introducing carbonic acid gas per rectum, which caused a corresponding increase in the interchange of oxygen. He had employed this combined method of electric light and carbonic acid gas treatment in fifteen cases, eleven of which had shown decided improvement. The electric light was thrown successively upon different portions of the chest in order to avoid overheating.

Dr. S. A. KNOPF said that he always took the opportunity to denounce the use of tuberculin as a diagnostic method. He felt sure that very few physicians would be willing to have tuberculin injected into themselves, or into any member of their families, and this being the case, they could not conscientiously employ it on others. That the tuberculin was unreliable in diagnosis was shown by the fact that the reaction had been obtained in syphilis, actinomycosis, and in purely anæmic individuals without any taint of tuberculosis. He had been told by Dr. Janeway of a case, seen in consultation, in which there was every reason to believe that a sudden generalization of a very

early tuberculous lesion had been produced by the family physician's having injected tuberculin. If painstaking inquiry and careful physical examination failed to make the diagnosis, he would personally rest content, and would treat the individual as if he had tuberculosis. The taking of the rectal temperature before and after exercise was one of the most hopeful of diagnostic resources in cases of suspected tuberculosis.

Dr. MAX EINHORN said that he had made many injections of tuberculin shortly after Koch's first publication of his method, and while no deaths occurred, he had noted in some of them an extension of the lesion, and in a number of others there had been hemorrhages apparently as a result of the tuberculin injection. While the electric light and many other agents would no doubt prove valuable in treatment, he was inclined to believe that even fifty years hence diet would remain preëminent in the therapy of this disease.

Dr. GEORGE MANNHEIMER said that if the body temperature rose half a degree or a degree after an ordinary walk it was certainly very suspicious of tuberculosis. Another diagnostic point was a tenderness of the upper dorsal vertebræ. Careful percussion of the extreme apices of the lungs was also very useful. He was not disposed to try the electric light or the carbonic acid gas treatment, because there was no experimental evidence to show that such methods possessed any bactericidal power, or were of special service. Such methods were certainly useful, but chiefly by reason of the fact that the patient was thereby kept constantly under medical supervision.

Dr. L. A. CONNER said that a few days ago a hospital patient had been given a rather large dose of tuberculin—if he recalled correctly, about one or two milligrams. As a result, there had been a terrific chill, hyperpyrexia and collapse, and for some time it was feared the patient would die. This experience was, of course, exceptional, but it was proper to report it. There were so many cases in which the diagnosis was doubtful that a reasonably safe and reliable method was certainly desirable.

Dr. Freudenthal, in closing the discussion, said that recent investigations did not substantiate the assertion that tuberculin caused a reaction in syphilis, anæmia, and other non-tuberculous disorders. A case was mentioned in which the question of extirpation of the larynx hinged upon the diagnosis, and the injection of tuberculin had cleared up this diagnosis. Hemorrhages had not been observed in recent years from the injection of tuberculin in the moderate doses now recommended.

## THE PRACTITIONERS' SOCIETY OF NEW YORK.

*One Hundred and Eighty-second Regular Meeting, Held on Friday, October 9, 1903.*

DR. CHAS. S. BULL, PRESIDENT, IN THE CHAIR.

**Injuries to the Chest Wall Complicating Medical Diseases.**—Dr. WALTER B. JAMES read this paper, in which he reported four cases of serious injury to the chest wall from coughing. They were all in persons at early middle life, three females and one male. One occurred in the course of a severe attack of measles, two in influenza and one in whooping-cough. In two of the cases the evidences of fracture of the rib were so plain as to make the diagnosis of this condition certain; in the other two cases the same diagnosis was probable but could not be made certain. All of the cases were characterized by intense localized pain over one of the ribs, or over the costochondral junction, with extreme tenderness to even the slightest pressure. In all of the cases the duration was long, the pain and tenderness sometimes persisting for several months. In no case was there any accompanying pleurisy or any other serious complication. In all of the four cases there was ultimately a complete recovery without any disability whatever.

Dr. James had collected forty cases of similar nature from the literature, and he expressed the belief from this, and his own experience, that this injury was more common than generally supposed. He suggested also the likelihood that many of the cases of severe localized thoracic pain so common in various pulmonary complaints associated with coughing may be due to injuries of greater or less severity but of the above nature. He referred to the possibility that many of the cases of intercostal neuralgia may be of this type.

Dr. H. F. WALKER, who opened the discussion, said he had never had such an experience as related by Dr. James, although he had frequently seen cases with localized pain produced by attacks of coughing, and this he had attributed to rupture of muscular fibers, the result probably of spasmodic action of the muscles. In his own cases he said that it would be difficult to believe that a fractured rib had occurred. He would exclude fracture of the rib where no protective callous could be found. The tenderness which followed rupture of muscular fibers was oftentimes persistent; and, in one case, this seemed to last longer than the time required for the healing of muscular fibers, giving rise to a persistent neuralgia; the neuralgia and tenderness being so great that it prevented the woman wearing a corset for some time. Thinking it might be *à propos* to the subject, he referred to the separation of a costal cartilage from the rib which would not require a great deal of force to produce. Such an injury he had received once while having massage; this troubled him for months, but healed without special treatment. He mentioned this as showing that such injury could be easily produced by force as slight as massage.

Dr. JOSEPH D. BRYANT said he was very much interested in the paper presented. It had never yet fallen to his lot to have seen a case of fracture of the rib arising in the manner described, *i.e.* from muscular action. In such cases he thought the diagnosis would rest between (1) laceration of the muscular fibers which were inserted into the rib at that situation, (2) fracture of the rib from muscular action, as described by the reader of the paper, and (3) intercostal neuralgia. In rupture of the muscular fibers of the serratus magnus, the seat of pain was usually situated laterally in a line with the axilla. In reviewing the anatomy of the intercostal nerves he stated that the upper six gave off anterior and posterior branches, the posterior branches supplying the integument covering the spinous processes, while the anterior branches ran forward and divided into lateral cutaneous branches in the axillary line; these latter subdivided into anterior and posterior branches. The main trunks finally go forward, becoming known as the anterior perforating branches. He had been able to locate three tender points of distribution, namely, one close to the spinous process, one laterally, and the third in front corresponding to the respective branches. Almost invariably the posterior perforating branch was present. The arrangement of the intercostal muscular construction was such that he believed it to be almost impossible to fracture a rib by intercostal muscular violence; the intercostal muscles bound the ribs together, making them very secure. He had no doubt but that there might exist a condition of the rib in which the diaphragmatic, and serratus magnus muscular contraction incident to severe coughing, might give rise to fracture. But, on account of the different ages of these patients he was inclined to believe that in many of the older fractures might be confounded with intercostal neuralgia. With regard to the lower ones being fractured, he could understand how the diaphragm might contract so vigorously as to cause such an injury to the rib. He could also understand why fracture should occur more frequently on the left than on the right side, because of the greater contraction there due to the presence of the liver on the right. He said it should be borne in mind that intercostal neuralgia was said to occur

more often on the left than on the right side; therefore, it was the more easy to mistake rib injuries of the left side for intercostal neuralgia. The amount of callus thrown out in fracture of the rib was very small indeed, but a great aid in diagnosis was the false point of motion produced by pressing upon the rib on either side of the seat of fracture. A separation of the costal junction should be carefully considered. In fracture pain and tenderness are quite easily and promptly alleviated by constricting pressure, and the period of cure more certain and definite than in neuralgia.

Dr. ROBERT ABBE said that he was particularly interested in one of the cases referred to by the reader of the paper, because it was one of the most unmistakable cases of fractured rib that he had ever seen. This patient had had a violent paroxysm of coughing while the body was in an uncomfortable position, and a fracture of the eighth rib in the axillary line had resulted. All the physical signs were present, including crepitus. He believed that there had been a fixation of the posterior portion of the ribs by the latissimus and serrati muscles, and the paroxysm of coughing, with the body bent, forced the anterior portion of the ribs against this barrier, causing the fracture of one rib.

Dr. BEVERLEY ROBINSON said he had never seen such cases as reported by Dr. James. He had hoped that the reader of the paper would touch upon a point that had recently been discussed before the Pennsylvania State Medical Society, *i.e.* how far contusions of the chest wall might predispose to tuberculosis. He had had recently at his clinic at Bellevue a man who was coughing all the time he was lecturing; the man came to the clinic to have his cough stopped. He did not succeed in stopping it, but he made suggestions which, he had no doubt, would aid him. He had seen cases of the most obstinate coughing, resisting all kinds of internal medication, which were arrested by a few applications to the lingual tonsil of tincture of iodine and glycerin. He had known other cases, resisting all internal remedies, corrected by attention to ulcerations about some growth in the commissure of the larynx. Often local applications must be made to cure certain obstinate coughs.

Dr. WALTER B. JAMES closed the discussion, saying that the purpose of his paper had been to bring before the society a brief report of five cases of tolerably serious injury to the ribs from coughing. He was much interested in the remarks of Dr. Walker. He had himself intended to speak of minor chest injuries from this cause, such as the slight tearing of a muscle, a number of which had come under his personal notice. These cases he had not included in his report. These accidents and injuries of the periosteum, accompanied by pain, reminded him of the conditions met with in veterinary practice; in which there was a lesion of the periosteum from a sudden strain. As a result of these injuries bony or fibrinous material was thrown out, causing a thickening and interference with tendons.

In answer to Dr. Bryant's remarks, regarding the frequency of intercostal neuralgia, and the likelihood that the cases reported had been really of this nature, he replied that one patient, who was a young physician, a man in robust health, had also been seen by Dr. Abbe, and here the fact of the fracture of the rib being present was beyond dispute. In another case also the patient had been seen by a well-known surgeon, who verified the diagnosis.

In the others the point of tenderness localized directly over the rib, with the fact that it was elicited on pressure upon the rib at a distant point, and the presence of a localized swelling made it perfectly clear that the cases were not simply neuralgias. He believed that such cases are more common than is generally supposed, and suspected that such injuries were often the origin of many chest pains that were attributed to intercostal neuralgia.

**Foreign Body in the Bronchus.**—Dr. ROBERT ABBE reported the case of a young lady who had inhaled a black-headed shawl-pin, two and a half inches long, made of steel, having a very sharp point. She had the pin between her teeth and, while laughing and talking hilariously, inhaled it. She came to St. Luke's Hospital chiefly on account of the persistent cough. There was no fever. An *x*-ray showed the pin head behind the heart, and the point near the middle line. The photographic plate showed the situation of the pin very well. It was shown in its true shadow. A large low tracheotomy wound was made in the attempt to get it. A small laryngeal mirror showed the glistening black pin apparently transfixing the left bronchus. After grasping the pin he attempted its removal by manipulation, but failed, for the point had traveled upward in its course, piercing the division of the bronchus. At first it was tightly fixed in its position, the head of the pin being further down, and efforts at removal tended to drive the point in. After working one-half or three-quarters of an hour he desisted. He bent a long wire into a loop and bent the loop back as a hook, and he then engaged the hook under the point of the pin near the bifurcation of the bronchus. A cannula was then passed down to the hook and an attempt made to get the point of the pin hooked up into the cannula, but it was too tightly fixed. The patient made a good recovery from this operation. The hook was left *in situ*, thinking it might be of service in devising some other operation. The second *x*-ray showed the pin to be occupying a different position, and the end of the pin engaged in the hook of the wire. The Trendelenberg position was used in the second operation in order to lessen the danger from inhalation pneumonia. The second attempt was as unsuccessful as the first. A third attempt was made—a failure followed. Nature was then given a chance. A fourth operation was performed and the pin was grasped a number of times. Three distinct subdivisions of the bronchus could be differentiated by the curved dressing forceps. At the end of one hour's trial he asked his house-surgeon, Dr. Hodgson, to examine the patient and appreciate the facility of introducing the forceps into the third bronchial subdivision, and, incidentally, if by good fortune the pin had finally become dislodged, to spread the forceps and see if, by chance, he might bring it out. The forceps caught the pin by its tip-point and brought it out of the tracheotomy wound, the sensation of the glass head turning the corner in different bronchial divisions, being plainly perceptible. Dr. Abbe wished to emphasize the importance of the Trendelenberg position to prevent inhalation of clots and to lessen the chances of the patient getting an inhalation-pneumonia, or any reaction, in cases of trachea surgery. It also showed him that almost any part of the trachea divisions may harbor foreign bodies which can be reached through a large low tracheotomy wound. His review of the literature of posterior thoracotomy reaching the trachea through the mediastinum showed such uniform mortality that a persistence for four operations through a trachea wound was more than justified by the result.

**A Case of Broncholithiasis.**—Dr. WALTER B. JAMES reported this case and showed a calculus coughed up by the patient. The patient was a woman fifty-five years old, and she presented all the classical symptoms of the condition. She gave a history of having always been well until fifteen months ago, when she took cold. Her cough persisted and soon became paroxsymal in character, like a whooping-cough, but without the whoop. She began to raise blood with these paroxysms in moderate quantity. She began to develop moderate oppression of breathing, lost some strength, but no flesh. Her paroxysms then gradually became more severe. The physical signs of emphysema were obtained over the chest. Over the middle of the right upper lobe in front there was a very slight dulness, and the respiratory murmur was cog-wheeled. An examination of the sputum showed mucus with very slight purulent mixture and much blood-stained. A few days after being examined she coughed up this concretion.

It was clear that the case was one of chronic bronchitis,

associated with the formation of bronchial concretions, situated probably in small dilatations of the terminal bronchi. Such cases are exceedingly rare. The one reported presented the classical symptoms belonging to this condition. Several explanations had been given of the origin of such concretions; one that they were the result of calcareous degeneration of bronchial lymph nodes, the calculi then ulcerating through into the bronchi; another that they were small calcareous nodules from tuberculous foci in the lung; another that, they were formed *in situ* in the small bronchi by the deposit of the salts of lime in stagnant sputum.

In the case reported, the unusual paroxysmal cough, which refused to yield to any remedies, the frequent expectoration of blood-stained sputum, the gradual onset of chest oppression, together with the absence of tubercle bacilli, and the absence of any marked physical signs of disease, pointed to the fact that the calculi were probably an important element in the genesis of the diseased condition.

Dr. H. M. BIGGS said he was reminded of an extraordinary case found on the autopsy table. The man had died suddenly on the street when apparently he was in the best of health. At autopsy it was accidentally found that the lung was filled with branched spiculi, with points very fine. They were of the nature of true bone. When left on the table the spiculi stood up as if the tissues were filled with pins. He had found such cases reported, but had never seen any explanation for the growth of bone.

## Books Received.

*While the* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

DISEASES OF THE NOSE AND THROAT. By CHARLES HUNTOON KNIGHT, M.D. 8vo, 423 pages. Illustrated. P. Blakiston's Son & Co., Philadelphia, Pa. Price, $3.00 net.

INTRACRANIAL TUMORS AMONG THE INSANE: A STUDY OF TWENTY-NINE INTRACRANIAL TUMORS FOUND IN SIXTEEN HUNDRED AND FORTY-TWO AUTOPSIES IN CASES OF MENTAL DISEASE. By I. W. BLACKBURN, M.D. 8vo, 94 pages Illustrated. Government Printing Office, Washington, D. C.

NURSES' GUIDE TO SURGICAL BANDAGING AND DRESSING. By WM. JOHNSON SMITH, F.R.C.S. 48mo, 167 pages. Illustrated. J. B. Lippincott Co., Philadelphia, Pa. Price, 75 cents.

HYPNOTISM, ITS HISTORY, PRACTICE AND THEORY. By J. MILNE BRAMWELL, M.B. 8vo, 478 pages. J. B. Lippincott Co., Philadelphia. Price, $4.50 net.

## Medical Items.

**Contagious Diseases—Weekly Statement.**—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending November 28, 1903.:

| | Cases. | Deaths. |
|---|---|---|
| Measles | 267 | 8 |
| Diphtheria and croup | 406 | 36 |
| Scarlet fever | 161 | 13 |
| Smallpox | ... | ... |
| Varicella | 98 | ... |
| Tuberculosis | 257 | 162 |
| Typhoid fever | 74 | 17 |
| Cerebrospinal meningitis | ... | 3 |

**Transportation of the Dead.**—The following proposed national rules to govern the transportation of the dead were adopted by the Conference of State and Provincial Boards of Health held in Baltimore, October 23 and 24:

"RULE 1.—The transportation of bodies dead of smallpox or bubonic plague from one State, territory, district, or province to another is absolutely prohibited.

"RULE 2.—The transportation of bodies dead of Asiatic cholera, yellow fever, typhus fever, diphtheria (membranous croup), scarlet fever (scarlatina, scarlet rash), erysipelas, glanders, anthrax, or leprosy shall not be accepted for transportation unless prepared for shipment by being thoroughly disinfected by (*a*) arterial and cavity injection with an improved disinfecting fluid; (*b*) disinfection and stopping of all orifices with absorbent cotton, and (*c*) washing the body with the disinfectant, all of which must be done by an embalmer holding a certificate as such, issued by the State or provincial board of health, or other State or provincial authority provided for by law. After being disinfected as above, such body shall be enveloped in a layer of dry cotton, not less than one inch thick, completely wrapped in a sheet securely fastened, and encased in an air-tight zinc, tin, copper, or lead-lined coffin or iron casket, all joints and seams hermetically sealed, and all enclosed in a strong, tight, wooden box. Or, the body being prepared for shipment by disinfecting and wrapping as above, may be placed in a strong coffin or casket, and said coffin or casket encased in an air-tight zinc, copper, or tin-lined box, all joints and seams hermetically soldered. For interstate transportation under this rule, only embalmers holding a license issued or approved by the State or provincial board of health, or other State or provincial authority provided for by law, after examination, shall be recognized as competent to prepare such bodies for shipment.

"RULE 3.—The bodies of those dead of typhoid fever, puerperal fever, tuberculosis, or measles, may be received for transportation when prepared for shipment by arterial and cavity injection with an approved disinfecting fluid, washing the exterior of the body with the same, and enveloping the entire body with a layer of cotton not less than one inch thick, and all wrapped in a sheet securely fastened, and encased in an air-tight metallic coffin or casket, or air-tight metallic box, provided that this shall apply only to bodies which can reach their destination within thirty hours from the time of death. In all other cases such bodies shall be prepared by a licensed embalmer holding a certificate as provided for in Rule 2. When prepared by a licensed embalmer, as defined and directed in Rule 2, the air-tight sealing and bandaging in cotton may be dispensed with.

"Rule 4.—The bodies of those dead from any cause not stated in Rules 2 and 3 may be received for transportation when encased in a sound coffin or casket and enclosed in a strong, outside wooden box, provided they can reach their destination within thirty hours from the time of death. If the body cannot reach its destination within thirty hours from the time of death, it must be prepared

for shipment by arterial and cavity injection with an approved disinfecting fluid, washing the exterior of the body with the same and enveloping the entire body with a layer of dry cotton not less than one inch thick, and all wrapped in a sheet securely fastened, and encased in an air-tight, metallic coffin or casket, or an air-tight metallic box. But when the body has been prepared for shipment by being thoroughly disinfected by a licensed embalmer, as defined and directed in Rule 2, the air-tight sealing and bandaging with cotton may be dispensed with.

"Rule 5.—In the shipment of bodies dead from any disease named in Rule 2, such body must not be accompanied by persons or articles which have been exposed to the infection of the disease, unless certified by the health officer as having been properly disinfected. Before selling tickets, agents should carefully examine the transit permit and note the name of the passenger in charge, and of any others proposing to accompany the body, and see that all necessary precautions have been taken to prevent the spread of the disease. The transit permit in such cases shall specifically state who is authorized by the health authorities to accompany the remains. In all cases where bodies are forwarded under Rule 2, notice must be sent by telegraph by the shipping embalmer to the health officer, or when there is no health officer, to other competent authority at destination, advising the date and train on which the body may be expected.

"Rule 6.—Every dead body must be accompanied by a person in charge, who must be provided with a passage ticket and also present a full first-class ticket marked "Corpse" for the transportation of the body, and a transit permit showing physician's or coroner's certificate, name of deceased, date and hour of death, age, place of death, cause of death, and all other items of the standard certificate of death recommended by the American Public Health Association and adopted by the U. S. Census Bureau, as far as obtainable, including health officer's or Registrar's permit for removal, undertaker's certificate, whether communicable or noncommunicable, the point to which the body is to be shipped, and when death is caused by any of the diseases specified in Rule 2 the names of those authorized by the health authorities to accompany the body. The transit permit must be made in duplicate, and the signature of physician or coroner, health officer and undertaker must be on both the original and duplicate copies. The undertaker's certificate and paster of the original shall be detached from the transit permit and securely fastened on the end of the coffin box. All coffin boxes must be provided with at least four handles. The physician's certificate and transit permit shall be handed to the passenger in charge of the corpse. The whole duplicate copy shall be sent to the official in charge of the baggage department of the initial line, and by him to the Secretary of the State or Provincial Board of Health of the State or province from which said shipment is made.

"Rule 7.—When bodies are shipped by express, a transit permit, as described in Rule 6, must be made out in duplicate. The undertaker's certificate and paster of the original shall be detached from the transit permit and securely fastened on the coffin box. The physician's certificate and transit permit shall be attached to and accompany the express way-bill covering the remains and be delivered with the body at the point of destination to the person to whom it is consigned. The whole duplicate copy shall be sent by the forwarding express agent to the Secretary of the State or Provincial Board of Health of the State or Province from which said shipment was made.

"Rule 8.—Every disinterred body, dead from any disease or cause, shall be treated as infectious or dangerous to the public health, and shall not be accepted for transportation unless said removal has been approved by the State or Provincial health authorities having jurisdiction where such body is disinterred, and the consent of the health authorities of the locality to which the corpse is consigned has been first obtained; and all such disinterred remains, or the coffin or casket containing the same, must be wrapped in a woolen blanket thoroughly saturated with a 1-1000 solution of corrosive sublimate, and enclosed in a hermetically sealed soldered zinc, tin, or copper-lined box. But bodies deposited in receiving vaults shall not be treated and considered the same as buried bodies, when originally prepared by a licensed embalmer as defined in Rule 2, and as directed in Rule 2 or 3 (according to the nature of the disease causing death), provided shipment takes place within thirty days from the time of death. The shipment of bodies prepared in the manner herein directed by licensed embalmers from receiving vaults may be made within thirty days from time of death without having to obtain permission from the health authorities of the locality to which the body is consigned. After thirty days the casket or coffin box containing said body must be enclosed in a hermetically soldered box.

"Rule 9.—All rules and parts of rules conflicting with these rules are hereby repealed."

**Health Report.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended November 28, 1903:

### THE FUNCTION OF MATERNAL MILK IN DEVELOPING THE STOMACH; A FACTOR HITHERTO OVERLOOKED IN ARTIFICIAL INFANT FEEDING.*

BY HENRY DWIGHT CHAPIN M.D.
NEW YORK.

FOR a number of years the discussions on artificial infant feeding have centered around the chemical composition of milk, and certain principles thus derived have been enunciated which more recent chemical research has shown to be erroneous. The older teaching that breast milk is alkaline and cow's milk is acid, and consequently alkali should be added to cow's milk, has been shown by Kerley, Gieschen and Myers to be wrong.[1] It is well known that good results are often obtained by adding alkalis to cow's milk, but the reason that has been given is not supported by the facts. Both human milk and cow's milk are acid to scientific methods of examination. This fact can be easily demonstrated, but an indicator more sensitive than litmus paper must be used (phenolphthalein).

At one time it was taught that success in infant feeding lay in accurate adjustment of the percentages of fat, proteids, carbohydrates, mineral matter and water of milk, plus alkali, to suit the infant's digestion. Now the same teachers are claiming that their treatment of the proteids of cow's milk was not the best and that a new method of adjusting the character of the proteids of cow's milk is proper and scientific. Further study has shown that the proteids of cow's milk are not the same as those of human milk, and not a simple mixture of caseinogen and lact-albumin as has been taught.

The attempt to establish a purely chemical method of feeding has not succeeded, but it has pointed the way toward a clearer understanding of the true principles of artificial feeding.

Fat, proteids, carbohydrates, and mineral matter are generic terms that cover a host of substances. Fat includes fat of meat, butter, lard, and table oils.

Proteids include all lean meat, flesh of birds, fish, eggs, curd of milk, and gluten of cereals.

Carbohydrates include cane sugar, milk sugar, starch of cereals, and potatoes.

Mineral matter includes the entire surface of the earth.

When it is taught that an infant's food should contain certain proportions of fat, proteids, carbohydrates, and mineral matter, a wide range of possibility exists, and what argument can be more logical than that of some manufacturers of prepared foods, who take the words out of the teachers' mouths and make up mixtures that contain the same proportions of fat, proteids, carbohydrates, and mineral matter that were said to be proper, and offer them to the public as representing what some authorities advocate? and what can be more illogical than the same authorities decrying all prepared foods as being unscientific? This is not to be construed as advocating the use of prepared infant foods, but is to show that the teachers of scientific infant feeding have not been in an impregnable position as far as such teaching is concerned.

All animals require fat, proteids, carbohydrates, mineral matter, and water, so it is only citing a general principle of nutrition when it is stated that an infant's food should contain them.

Clinical results are greatly in favor of the fat, proteids, and mineral matter derived from milk of some kind as the food for infants. The source of the carbohydrates does not seem to be as important.

It does not strengthen the situation to teach that milk should be used in infant feeding because it contains animal proteid. Any one could add dried blood, egg albumen, or desiccated meat to a food and claim that it met all the requirements of the authorities, as it contained animal proteid.

*Young animals need milk because milk supplies forms of proteid that have special and peculiar functions that other forms of proteids do not have.* It is to this feature of the proteids of milk that attention is here specially called. To bring out clearly this function, a little sketch of the place of milk in the animal economy will be helpful.

The reproductive process in most animals consists in the development of a single cell into a perfect organism, from food derived from the parent's body. The great differences between animals lie in the manner in which this food is supplied to the germinal cell.

In the case of a hen, all of the food is separated from the mother's body at one time, enclosed in a shell, from which the chick emerges perfectly formed. In some other birds the organs of locomotion are developed after hatching, from the food brought by the parents.

In all forms of animal life the parent either nourishes the young from its own body, or brings it suitable food until it is able to secure food for itself, when weaning takes place.

In animals that suckle their young the greatest variety of methods of supplying nourishment to the germinal cell is seen, but it is not all supplied in one way, in one form or at one time.

Fig. 1. Duck-bill (Vogt & Specht). Lays eggs in nest.

Figs. 1, 2, and 3 show an animal that makes a nest in the ground, lays eggs with a lime shell,

*Read before Pediatric Section of New York Academy of Medicine, November 12, 1903.

hatches them, and then suckles the young, whose mouths are unlike their parent's, but perfectly adapted to cover the peculiar openings of the mammary ducts.

Fig. 2. Young Duck-bill as hatched (Owen).

Fig. 3. Mammary outlets of the Duck-bill (Owen).

Figs. 4, 5, 6, 7 show an animal that lays an egg which is hatched in an abdominal pouch and the young is there suckled, the mouth of the young and the outlet of the mammary glands being adapted to each other.

Fig. 4. Spiny Ant-eater (Vogt & Specht).

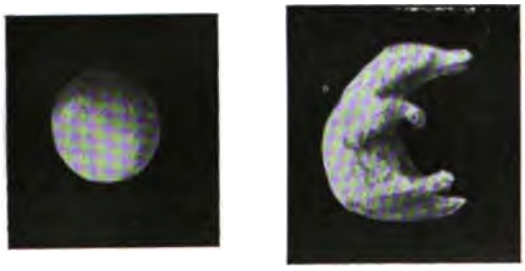

Fig. 5. Egg laid and hatched in mammary pocket shown in Fig. 6 and resulting fœtus. Life size. (Photographed from specimens in the Zoological Collection of Columbia University.)

Fig. 6. Mammary pocket of Spiny Ant-eater (Wiedersheim).

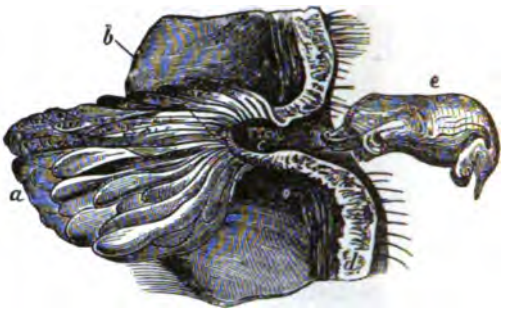

Fig. 7. Mammary gland and fœtus of Spiny Ant-eater (Owen).

Figs. 8, 9, 10 show an animal which lays no eggs but gives birth shortly after impregnation to a rudimentary fœtus whose mouth grows fast to a teat in the mother's abdominal pouch. Nearly all of this animal's development takes place on this teat. Its increase in weight is from about one-half ounce at birth to eight pounds at weaning. The mother ejects milk into a specially adapted gullet (Fig. 10), which does not connect with the wind-pipe until the young animal is able to suck, when its mouth ceases to be adherent to the teat. As development proceeds, the young thrusts its head out of the pouch (Fig. 8) and nibbles at the food its mother eats. A little later it leaves the pouch for good. Here is the highest development of the mammary function.

Fig. 8. Kangaroo at weaning time (Vogt & Specht).

Fig. 9. Mammary fœtus of Kangaroo in pouch

Fig. 10. Head of fœtus hemi-sected to show adaptation of teat to mouth.

Figs. 9 and 10. Life size photographs of specimens in the Zoological Collection of Columbia University.

Fig. 11 shows the young of the American opossum adherent to the teats.

Fig. 11. Young of Opossum adherent to teats. Half life size. Photographed from specimens in the Zoological Collection of Columbia University.

In none of these animals is there any placental connection with the mother. In past ages this method of reproduction predominated over the earth, but animals whose young were nourished in the uterus for a greater or lesser period were more successful in the struggle for existence. Modern mammals are distinguished by the formation of the chorion, which develops into the placenta, through which the nourishment is supplied to the forming organism, mammary development and nutrition not being so pronounced, although important. At one time mammary nutrition and development of the fœtus were primary. Now they are secondary in nearly all forms of animal life.

In the process of development from the germinal cell into the perfect organism, all animals pass from very simple forms to more complex ones. In the early fetal forms it is impossible to tell what kind of animal is going to be developed, as will be seen by a glance at Fig. 12.

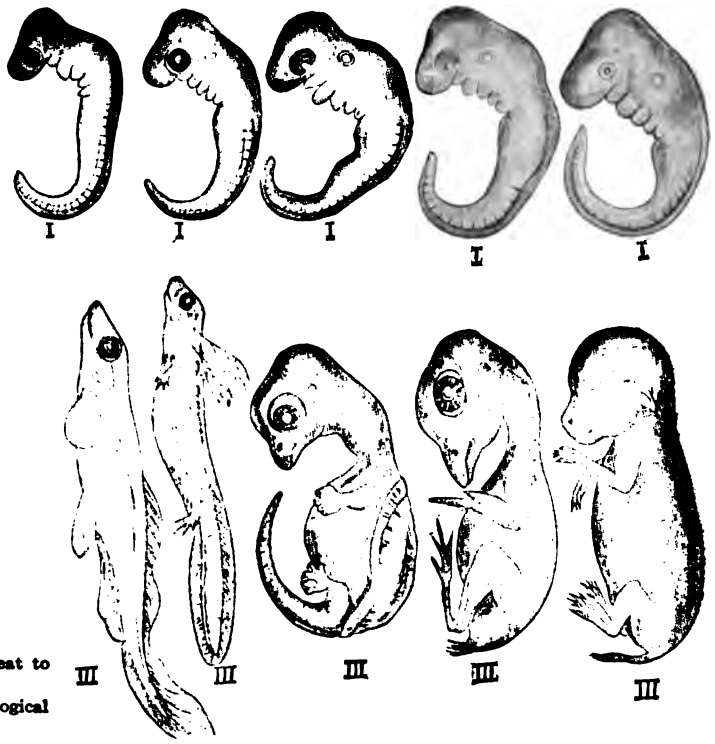

Fig. 12. Earlier and later fetal stages of Fish, Salamander, Tortoise Chick, Rabbit (Haeckel).

The digestive tracts of all animals are alike and simple in the early fetal stages and develop into the more or less complex forms of the adult before the time of weaning, the mammary secretions having a great deal to do with producing this development.

Fig. 13 shows the development

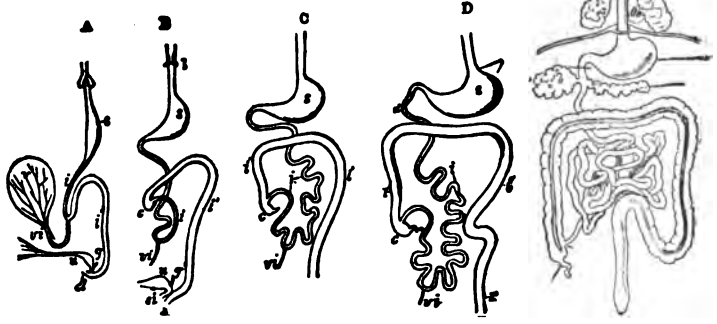

Fig. 13. Development of human digestive tract (Allen Thomson and Wiedersheim).

of the human digestive tract from a very simple tube into the specialized organs of the adult.

Figs. 14 and 15 show the stomachs of a number of mammals and the digestive tract of a cow. The upper part of the stomach of a cow is not developed by milk, but by grass after the true or fourth stomach has been developed by milk.

The digestive tract of the kangaroo at birth (Fig. 9) is very simple and nothing like what it is at weaning, and the stomachs of most mammals at birth are not the same as at weaning; *a profound change in the digestive tract takes place during the suckling period.*

Colostrum, the first secretion of the mammary

glands, is totally different from milk in composition and physical properties, but is particularly fitted for starting up the intestinal digestive process.

A high authority has stated that colostrum rep-

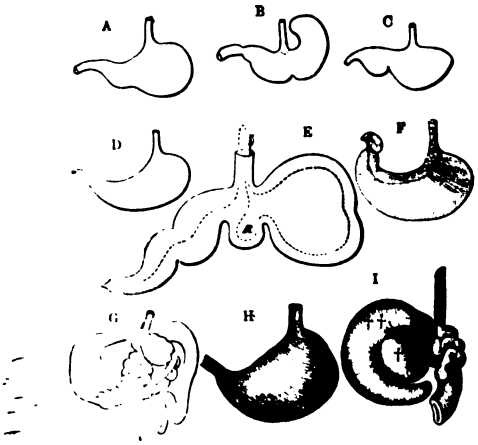

Fig. 14. Stomachs of different mammals (Wiedersheim). A. Dog. B. Rat. C. Mouse. D. Weasel. E. Ruminant. F. *Human*. G. Camel. H. Spiny Ant-eater. I. Three-toed Sloth.

resents an abnormal condition. If this is abnormal, it has happened to all species of mammals.

Henry[3] of the Wisconsin Experiment Station, who has studied the practical raising of many species of domestic animals, reports as follows:

"Colostrum: This first milk is exceedingly important to the young animal at birth, and should never be withheld from it, for besides yielding nutriment it possesses properties which serve to cleanse the alimentary tract and properly start the work of digestion. . . . The calf should always get the first milk (colostrum) of the cow, as this is necessary for properly clearing the bowels and starting the digestive functions. . . . It is of the highest importance in horse rearing that the young start in life in full health and vigor, and to this end the foal should very soon after birth take a good draught of the colostrum or first milk of the dam. . . .

Fig. 15. Digestive tract of cow (Colin & Muller).

"If the young lamb is unable to draw milk within a few minutes after birth, it should have help to secure this first and most important feed. With the first fill of milk from the dam, the new-born lamb becomes comfortable and is usually able thereafter to take care of itself."

It is well known that within a few days after birth normal milk displaces colostrum, which is composed of fat, proteids, carbohydrates, mineral matter and water, as is milk. Milk forms curds in the stomach, which is not the case with colostrum. As these curds are formed from a portion of the proteids of the milk, this is a case where nature quickly alters the character of the proteid of the food to suit a particular purpose.

The digestive secretion of the stomach of an adult is essentially rennet, hydrochloric acid and pepsin. The function of the stomach is to act as a food reservoir and to break down proteid tissue, so that it can be easily and completely digested in the intestine. Very little complete proteid digestion takes place in the stomach.[5] Before pepsin will act on proteid, a combination of the acid and proteid must take place. In young animals little acid is secreted in the stomach and gastric digestion is not prominent.

One thing about infant feeding that is noticeable is that, as the infant's stomach develops and becomes larger and stronger, longer intervals between feedings become necessary.

It may be argued that the older infant takes more into its stomach; but such an infant's stomach is larger and more vigorous, and should empty as soon as, if not sooner, than at birth.

During the colostrum period there is very little secretion in the stomach, and colostrum is particularly fitted for intestinal digestion. As soon as milk begins to displace the colostrum, there appears an abundant secretion of rennet in a calf's stomach, which acts on the proteid of the milk and changes the milk into a soft solid curd, or junket. Pepsin will not attack this altered proteid or curd of milk, which, being soft, is easily passed into the intestine and there digested. Thus the first function of milk is to fit the stomach for passing soft food into the intestine. The motor function is developed first. Rennet does not act on colostrum and is secreted in small amount during the colostrum period.

As soon as a little acid is secreted by the stomach, it combines with a portion of the curd to form a definite compound which is readily attacked by pepsin.[6] This compound is denser and tougher than the rennet curds, and unfit for intestinal digestion. The stomach has now something to do besides emptying itself, and the food remains longer in the stomach to give the pepsin time to act. As the secretion of acid increases, more of the curd combines with the acid, and there is more work for pepsin. In this way, as fast as the gastric glands develop they find work awaiting them. Thus it is that the stomach is called into action, and longer intervals between feedings become necessary. If there was not some such provision, mother's milk ought to change in character as the digestive function becomes stronger to meet the stronger digestive juices, or atrophy of the digestive glands would ensue. As it is, mother's milk adapts itself to a weak infant or to a strong one. If the gastric secretion is vigorous, the milk becomes more solid and stays longer in the stomach; if weak, the milk forms a softer clot which easily passes into the intestine in a condition to be rapidly digested there. *Mother's milk and the secretions of the infant's gastro-intestinal tract automatically adapt themselves to each other.* If mother's milk itself changed in character according to the age of the infant, it would never agree with a puny, backward infant; and if milk did not turn into a solid, but remained a fluid, the stomach would not be prepared for solid food at weaning, for there would be nothing to properly develop the motor and glandular functions.

It has been seen (Figs. 2, 3, 7, 10 and 11) that, anatomically, young animals and mothers are perfectly adapted to each other; *they are also functionally adapted to each other.*

In the change from colostrum to milk, the mother alters the character of the proteid supplied, and the infant's digestive secretions change at the same time for a specific purpose. The proteid of mother's milk adapts itself to the young animal's digestive secretions.

A glance at the different stomachs (Fig. 14) will suggest that one form of proteid would not fit them all unless their digestive juices had different effects on it. It is a familiar fact that the milks of different species form different kinds of curds under the action of the same rennet and acid, and universal experience has shown that the proteid or curd of the milk of the lower animals does not perfectly fit a baby's stomach. The only conclusion possible is that the proteids of different milks are not the same from a functional standpoint, no matter how nearly alike they may be in ultimate chemical composition.

In artificial feeding it is essential to supply as much fat and carbohydrates as is found in breast milk to serve as fuel for the body, and as much proteid and mineral matter as is found in breast milk to build up a strong body, or anæmia, rickets, and general malnutrition will follow. It is also essential that a portion of the proteid shall be of a form that will develop the stomach, as the lack of such food will profoundly affect the general nutrition.[3]

Fresh cow's milk is the only available source of such a form of proteid, and for this reason fresh milk should be the backbone of the baby's food. However, the proteid of cow's milk does not fit a baby's stomach and must be altered in some way to make it fit. In the cow, digestion is principally gastric, and food slowly leaves the stomach. Cow's milk curds in such large masses that it cannot readily leave the stomach. In man, finely divided food that readily leaves the stomach is natural, and human milk does not form solid curds, but flakes.[4] Alteration of the character of cow's milk may be brought about by a number of methods, and one method may succeed when another fails.

Sterilizing, pasteurizing, or heating cow's milk alters it chemically so that rennet will not act upon it readily. This fact is familiar to every cook, as on the packages of rennet sold for making junket for desserts will be found: "Use pure sweet milk, heat carefully until just lukewarm, remove at once from the fire, as you may overheat it, as milk or cream that has been boiled, sterilized, condensed or evaporated cannot be used." Heating milk also destroys bacteria that produce acid, an excess of which would combine with the rennet curds and form a dense mass far beyond the capacity of the infant's peptic digestion. Investigation has shown that pasteurized or sterilized milk as fed to infants is not at all free from bacteria, so a part of the benefit of heating milk lies in altering the character of the milk and preventing the formation of acid.

The addition of alkalis to cow's milk retards the action of rennet or neutralizes the acid of the stomach, and thus throws the milk into the intestine more rapidly and in a softer condition.

The dilution of cow's milk with plain gruels holds the curds apart and allows more rapid emptying of the stomach.

Diluting cow's milk with dextrinized gruels supplies the mechanical effect of plain gruels, puts a modicum of starch in the infant's stomach, adds a natural promoter of gastric secretion to the food[5] and supplies some readily absorbable food which is found in all milks, but which is reduced in quantity in diluted cow's milk.

No artificial food can be made up that will automatically adapt itself to the normal infant as maternal milk does. The infant gets from the mother the same percentages of fat, proteids, carbohydrates, mineral matter and water, whether its stomach is weak or strong; *its digestive secretions determine how and where digestion shall take place.* The skilful infant-feeder learns to discover functional derangements. He may find that the gastric function is not normal and will possibly add a large quantity of alkali to the milk to cause it to rapidly leave the stomach as a fluid, or he may decide that a nearly soluble food is required, and peptonize the milk or stop milk entirely and feed dextrinized gruel getting back to milk gradually. Reducing the quantity of proteid of cow's milk to .25 or .50 per cent., except temporarily to correct functional disturbances, is not justified, if another form of nucleoalbumin, with more or less cow's milk, can be digested. Indigestion is being treated by partial starvation where such low proteids are supplied. It may be found that the infant is taking a soluble food which requires little digestive effort, and is not doing well. A change to milk causing immediate improvement suggests that the stomach was craving work which the curding of the milk supplies.

A careful study of the experience of all pediatricians will show that success has not followed rigid adherence to any rule of feeding, but along adaptation of the food to the state of the infant's digestion, the most radical changes in the character of the food sometimes giving good results. In these instances the food was inelastic in its character, and only a portion of the proper functional development was being produced. The radical change of food produced a development that was needed.

Normal maternal milk supplies the necessary quantities of fat, proteids, carbohydrates, etc., for proper structural development and maintenance of the vital processes, in forms that automatically adapt themselves so as to develop the digestive functions of the growing animal.

It is easy to make up a food that will contain the same quantities of fat, proteids, carbohydrates, etc., as maternal milk, but experience and study only will enable the infant-feeder to do what nature does automatically—adapt the food to the conditions actually present and ensure proper functional development. Biology must be considered fully as much as chemistry in the study of artificial infant feeding.

**Victims of the Jungle.**—It is noted in *The Times* of London that in 1901 more human beings were killed by wild animals than in any year since 1875 except one, and reached a total of 3,651, while last year it was 2,836; and the number of deaths from snake bite was 23,166. Tigers killed 1,046 persons, of whom 544 perished in Bengal, 65 being in a single district. This was due to the depredations of a man-eater, for the destruction of which a special reward was offered without avail. In another district, where 43 persons were killed, most of them fell victims also to a man-eater. Wolves slew 377 persons. Eleven thousand one hundred and thirty deaths took place in Bengal alone from snake-bite, 3,258 of these being in the Patna division, while 5,110 deaths took place in the United Provinces; 80,796 cattle (an increase on the previous year) were killed by wild animals last year, and 9,019 by snakes. Tigers killed 30,555 of these, leopards 38,211, and wolves and hyenas most of the remainder.

## CYCLICAL ALBUMINURIA.*

By ARTHUR R. ELLIOTT, M.D.,
CHICAGO.
PROFESSOR OF MEDICINE, POST-GRADUATE MEDICAL SCHOOL.

CYCLICAL ALBUMINURIA is the name employed by Pavy to designate certain cases of albuminuria occurring without demonstrable organic disease of the kidneys in individuals otherwise in apparent health. The term "cyclical" emphasizes a feature of the albuminuria which is often its most striking characteristic, *i.e.* its rhythmical appearance under the influence of posture and activity, and its disappearance while the body is at rest. Cases of this type show albumin in the urine voided during the day, whereas the morning and evening urines are free from its presence. It is or is not influenced by diet, and may even be absent after exercise. The upright posture seems to be the immediate exciting factor which induces the albuminuria. The majority of cases are discovered accidentally when no such development is anticipated. It is necessary in making a diagnosis to confine the term to albuminuria in its clinical, and not its laboratory, sense—only the albuminuria recognized by the common chemical tests—heat, potassium ferrocyanide, nitric acid—being admissible.

The greatest care must be taken to exclude incipient renal diseases of all kinds, anæmia (especially the essential forms), and circulatory disturbances. With the exception of the presence of albumin, the urine must conform in all respects to the normal standard; and vascular tension, retinal changes, and cardiac hypertrophy must be absolutely excluded. Cyclical albuminuria belongs to the class of so-called functional albuminurias, forming one of many types included under that heading. Other forms have been variously named, transient, intermittent, minimal, adolescent, postural, and dietetic. It is probable that these do not constitute different clinical entities, but that a common pathological condition underlies them all, individual cases reacting in such different ways to special exciting causes as to give them apparent distinctive characteristics. Cyclical albuminuria is most commonly met with in boys and young men. The age at which it develops is a matter of some uncertainty, because the symptom is almost invariably discovered accidentally during analyses performed for other purposes.

The question of this form of albuminuria is always of great interest to the clinician, because of the difficulties encountered in separating the condition from organic renal disease. The great question and the one necessary factor for the satisfactory classification of this phenomenon is the elucidation of the relationship which it bears to degenerative lesions of the kidney.

I submit the clinical histories of two cases of cyclical albuminuria which possess features of unusual interest.

CASE I.—A. C., a lad of fourteen years, was referred to me early in September last by Dr. D. R. McMartin of Chicago, for advice regarding an albuminuria of peculiar type. Patient presented at the time of consultation the appearance of health. He is possibly a little undersized for his age and weighs eighty-six pounds, which is about his average—normal. Patient is a very light blonde, with a clear, transparent skin, and mucous membranes of good color. He is very fond of out-of-door sports and athletics, and during the past summer has led the typical boy's life of activity in the country. A point of possible clinical importance is his strong resemblance, both physically and in temperament, to his father, who has had chronic diffuse nephritis for twelve years. The only other feature of interest in the family history is a decided gouty heredity on the mother's side. Patient passed a healthy infancy, and at the age of two years had pneumonia, from which he recovered without unusual length of convalescence. He had, however, three subsequent acute pulmonary attacks, which were also diagnosed as pneumonia, during the three succeeding winters. At the age of eight, he contracted diphtheria, which was followed by a tedious convalescence lasting three months. During no one of these infections was there any renal complication. In February, 1903, an acute febrile condition developed and persisted three weeks, with a maximum temperature of 103°F. This illness, in the absence of other definite indication, was diagnosed influenza, although scarlatina was suspected, owing to the presence of severe throat symptoms and the fact that the disease was prevalent at the time in the immediate neighborhood. No eruption appeared, nor was desquamation observed.

Analysis of the urine during the progress of this fever revealed the presence of albumin. On March 13 the amount of albumin attained a maximum of 5 per cent. bulk, and ten days later had declined to a mere trace. At no time was there any œdema or uræmic manifestation. Several analyses made after convalescence was established revealed the presence of an intermittent albuminuria, which was increased by activity. No subjective symptoms were complained of at the time of first consultation with the writer, on September 11, except a troublesome, intermittent, frontal headache, which was accompanied by transient dizziness. It had been observed that patient tired more quickly than usual. Physical examination revealed nothing of interest. The condition of the heart and arteries, which was noted with particular care, indicated no cardiac hypertrophy, nor vascular tension. The blood was normal in all respects. No enlargement of the glands was observed, and ophthalmoscopic examination proved negative. The urine was found to contain one-half per cent. bulk of serum albumin, traces of nucleoalbumin, but no casts. The bodily temperature was 99.5° F. From that time until the present, the urine has been carefully observed. Mixed albuminuria has been constantly present during the hours of activity. This albuminuria includes serum albumin and nucleoalbumin. The amount has ranged from a mere trace to 28 per cent. bulk of precipitated coagulum. Unusual care was observed in the search for casts, but in no instance were these bodies found present. Large numbers of mucous cylindroids have always appeared in the albuminous urine and renal cells have frequently been found in small numbers. The urine of rest has invariably been free from the slightest trace of any form of albumin, and in the evening urine either no albumin was found, or but a trace of nucleo albumin.

The taking of meals (unless combined with activity) seemed to have no influence in causing albuminuria. In order to determine whether the albuminuria was the result of bodily activity or of the upright position, patient was instructed to exercise the limbs as actively and continuously as possible for one hour, while lying flat in bed. The urine after this procedure contained no albumin. On another occasion, after the patient had stood erect for one hour with as little movement as possible, the urine was found loaded with albumin. The bladder was emptied before each one of these tests was begun. The tide of albuminuria was found to set in about one hour after rising, the first indication being the appearance of traces of nucleoalbumin. The maxi-

*Read at the annual meeting of the Mississippi Valley Medical Association at Memphis, Tenn., October 9, 1903.

mum was reached about 3 P.M. and by evening it had again subsided. Other features of interest regarding the urinary condition were the frequent presence of precipitated phosphates and the existence of a pathologic indicanuria. That the latter factor had little if any influence in causing the albuminuria seemed proved by persistence, of the albuminuria unchanged, after the indicanuria was eliminated by colonic irrigation and laxatives. In all other respects the urine conformed to the normal standard.

Of unusual interest in the history of this case is the behavior of the bodily temperature. This was systematically observed and recorded for ten days. A synchronous temperature curve was found to exist with the albuminuria. An elevation of from one-half to one degree was constantly noted during the middle of the day; the morning and evening temperatures being invariably normal or slightly below normal. The influence of bodily activity in raising the temperature was nicely shown by having the patient go through a short series of calisthenic exercises which sufficed to raise the bodily temperature from 98.4° to 99° F.

The presence of fever would point to the existence of a toxic element, and the question of there being a fatigue pyrexia is suggested, owing to its connection with exertion. It is doubtful whether any direct relation existed between the fever and albuminuria, for it was determined by the expedients already described that the albuminuria in this case was a pure postural albuminuria, unaffected by exercise in the recumbent position, and appearing under the influence of the upright position alone. It is probable that the pyrexia in this instance was due to lowered resistance and consequent excessive systemic reaction to stimuli.

CASE II.—B. D., æt. sixteen, first came under observation April 27, 1901, for post-scarlatinal nephritis. There was no œdema or secondary systemic evidence of the renal inflammation, but the urine gave frank reactions, for albumin, and many hyaline, epithelial and granular casts and renal epithelia were present in the sediment. The urine was systematically observed each day during the ensuing month, albumin being invariably present, ranging in amount from a trace to 2 per cent. bulk of moist precipitate estimated by centrifuge. Casts were constant features of the urine sediment. A marked decline in the amount of albumin was observed to begin May 30, and by June 24 there was no longer more than a trace to be discovered. Casts of every kind had disappeared by June 12, and a trace of nucleoalbumin was the only morbid feature of the urine on July 28, when my patient left the city for a summer outing. This was the first occasion upon which nucleoalbumin was detected. About ten days previous a system of observation of the urine voided at different times of the day had been conducted, with the result that the night urine voided on rising in the morning was found to contain no albumin; one hour after rising gave plain reactions, which had increased to one-fourth per cent. bulk by the middle of the morning. No casts were found in any of these specimens. The pulse was soft, the sphygmogram showed no wave of tension, and no cardiac hypertrophy or second aortic accentuation could be made out. The succeeding six weeks were spent by my patient at the seashore, the only restrictions imposed being against prolonged exertion and sea bathing. Upon his return, September 19, patient displayed every evidence of robust health. He was absolutely without evidence of secondary cardiovascular involvement; was excreting a normal quantity of urine, which contained 400 grains of urea to the twenty-four-hour specimen, and yet the urine of activity never failed to reveal serum-albumin, usually associated with nucleoalbumin, but no casts were discoverable. During the two years which have elapsed since that time, the urine has been repeatedly examined, with much the same results. The urine of recumbency fails to reveal serum-albumin, although occasionally traces of nucleoalbumin have been observed in the morning urine. The albuminuria of the active hours has attained a maximum of 2 per cent. bulk and a few specimens have revealed hyaline casts in very sparse numbers. The results of my last analyses, made October 1, 1903, are as follows: Urine voided on rising in the morning contains traces of both serum-albumin and nucleoalbumin. At midday the urine yielded one-half per cent. bulk, which had increased to one and one-fourth per cent. in the urine voided during the early evening. Microscopical examination of four slides of the highly concentrated sediment of the last urine revealed eight or ten narrow, very short hyaline bodies, evi dently casts, but not typical, and scattered renal cells. Meanwhile, although a careful watch has been maintained to detect the earliest evidence of developing tension and cardiac hypertrophy, no sign of such changes can be made out and the lad enjoys robust health; has developed normally, and is now a youth of five feet nine inches height and 142 pounds weight.

An element of importance, especially from the prognostic standpoint, is the existence of chronic nephritis in the immediate ancestry of both of my patients. The father of Case I has for twelve years suffered from chronic diffuse nephritis, with marked albuminuria, and is at present under the care of the writer. The father of Case II has been under my continuous observation for six years, the renal lesion being chronic interstitial nephritis with minimal albuminuria and well-developed cardiovascular accompaniments.

A second feature of interest in the cases reported is the nucleoalbuminuria associated with serum-albuminuria. This association has been noted by other observers, and in addition to nucleoalbumin, globulin and albumoses have occasionally been observed in these cases. Regarding the significance of nucleoalbumin much information is needed. It is the chief constituent of cells and occurs when cell elements undergo degeneration or are otherwise altered. It is often present in acute desquamative nephritis, and in the cases here reported may have been a feature of the urine from the start and escaped detection. Its persistence would seem to indicate the disintegration of renal epithelium.

The most interesting feature of these two cases is the direct connection between the cyclical albuminuria and preceding acute infectious nephritis. There exists some doubt as to the exact nature of the original infection in Case I, but whether it was influenza or atypical scarlatina matters little as far as the renal end-product is concerned. In Case II the direct connection with scarlatina is clearly established. In both cases the nephritis was a mild process, attended by little systemic disturbance, slight renal desquamation, and moderate albuminuria. It may be safely inferred that in both instances the lesion was glomerular, a mild cortical involvement. The gradual subsidence of the nephritis, disappearance of renal inflammatory bodies from the urinary sediment and passage of the albuminuria without remission from the organic continuous form to the cyclical variety, is clearly manifest in the clinical development of both cases. The resulting type of albuminuria conforms perfectly to Pavy's description of cyclical albuminuria, and the absence of casts completes the requirements that author

lays down for a diagnosis of this condition. I cannot doubt the accuracy of my physical findings, which enable me to exclude the element of cardiovascular fibrosis in these cases, and the excellent quantitative urinary results constitute ample proof of unimpaired adequacy of the kidneys.

The observation constituted by these cases of a direct sequential connection with acute infectious nephritis has been previously made by Johnson, Osswald, and Marie. Such cases have usually been regarded as not conforming to the true type of functional albuminuria, and have received consideration in a separate class. There seems to the writer to be no warrant for this distinction, for not only are the clinical manifestations identical with other cases without demonstrable connection with preceding nephritis, but our failure to establish a renal history is no proof of its non-existence. That acute nephritis may exist without subjective symptoms is a fact not sufficiently appreciated. A case at present under observation furnishes excellent demonstration of that fact.

A recent graduate in medicine, twenty-six years of age, three months after an attack of influenzal pneumonia, accidentally discovered albumin in his urine, while engaged in laboratory work. Associated with the albuminuria were many hyaline, epithelial, and granular casts, blood cells, and renal epithelia. These conditions have persisted for a period of six months, and at present there are many casts, blood and renal cells and 1 per cent. bulk of albumin in the urine. Despite the nephritis, this patient has gained twelve pounds in weight since the discovery of the renal condition and is entirely without symptoms or physical signs of disease. He declares that did he not know of the albuminuria, he would consider himself in the best of health.

Unfortunately, the fact that no well-authenticated case of functional albuminuria has come to autopsy renders the pathology of this condition a matter of theory, and it is as speculative and varied as conclusions so supported usually are. It seems to the writer that in attempting to explain what was not capable of actual physical demonstration, the endeavor has been to create exceptions to general pathologic laws. The problem demanding solution is how to account for certain anomalous cases of albuminuria, intermittent in character, unaccompanied by systemic indications of renal disease, and spontaneously disappearing without apparent detriment to the kidneys in a majority of cases—a minority succumbing to Bright's disease.

The infectious or toxic origin of every nephritis is a well-established law. The existence of nephritis in childhood presupposes an acute infection of some sort, usually one of the eruptive fevers, although influenza, typhoid fever, diphtheria, and even mumps, may cause it. The observations of Johnson, Marie, and Osswald, already referred to, and the two cases herewith submitted, demonstrate beyond question that an acute infectious nephritis may gradually lose its active qualities and pass into a cyclical albuminuria. Functional disturbance cannot exist without organic change, although this may be beyond our means to recognize. There can be no exception to this law in the kidneys more than in other organs. Most cases of cyclical albuminuria are discovered accidentally, with no means of estimating how long they may have existed previously. I believe these cases to be the aftermath of a prĕexisting, undiscovered, glomerulitis, caused by one of the acute infections in which early life is so prolific.

There is no characteristic of cyclical albuminuria hich is not shared by the albuminuria of organic renal disease. This is true of intermittency and the influence of posture and activity in causing its appearance and increase. The absence of casts, originally claimed by Pavy as significant of cyclical albuminuria, can no longer be maintained, the introduction of the centrifuge into urinary work having resulted in the frequent discovery of these bodies. The quantity of albumin forms no criterion, for it has been well known since the time of Bright that the quantity of albumin is no accurate guide to the severity and extent of the renal lesion. The only peculiarity that remains to distinguish cyclical from true renal albuminuria is its existence for months and years without systemic indications of nephritis and its frequent spontaneous disappearance, leaving behind no indication of renal impairment.

In post-mortem work it is a frequent experience to see in the kidneys indications of healed lesions—scars or areas of atrophy, showing where localized inflammatory processes once existed and became healed without detriment to the organ as a whole.

Klebs demonstrated many years ago that post-scarlatinal nephritis had its beginning in the Malpighian glomerules—was in the first instance a glomerulitis. This discovery was taken up and extended by other pathologists until it became established that every nephritis had its origin in the glomerular system. It is possible for this initial lesion of an acute nephritis to take place and proceed no farther, the tubular epithelium and connective tissue stroma escaping involvement. The cases recited seem to demonstrate clearly this localized glomerulitis. This fact accepted, the subsequent cyclical albuminuria becomes merely evidence of a defective glomerular condition, a few leaky glomerules, as yet imperfectly repaired, permitting under the high intraglomerular blood-pressure of the upright position the passage of albumin into the urine. If these views are correct, every cyclical albuminuria must be looked upon as simply a phase of mild degree of a true nephritis, which has preceded it.

This substitutes an organic for a functional explanation of the phenomenon, and views every case as being directly or remotely associated with a genuine nephritis, often latent, localized, and escaping detection, but invariably present. This view does not necessarily imply a serious prognosis. The disease is not active and progressive, but naturally tends to resolution. Under suitable conditions of diet and hygiene the symptom will in the majority of cases eventually disappear. Tessier and Merley were able to follow twenty-eight cases during periods varying from nine to thirteen years. Four of the twenty-eight cases developed Bright's disease, a percentage of 14.28. The possibility of this outcome must be kept in mind in treatment and prognosis.

---

**A Rare Cerebral Complication in Malaria.**—The patient of P. A. Nightingale was an army officer aged thirty-two years: was taken down with malaria in the usual way. On the morning of the third day it was noticed that fluids regurgitated through the nose. The voice was hoarse and husky. The fauces were congested, the uvula elongated and œdematous, while the anterior half of both vocal bands was swollen and puffy with incomplete approximation on phonation. Four days later there was a decided improvement of all symptoms, but it was four months before the voice had regained its normal qualities. The throat symptoms were due, in the author's opinion, to embolism caused by the malarial parasite in some capillary vessels of the cerebral centers. The highest temperature during the attack was 104.6° F.—*Journal of Tropical Medicine*

# MUSCLE TONUS AND TENDON PHENOMENA.*

By JOSEPH FRAENKEL, M.D.,
AND
JOSEPH COLLINS, M.D.,
NEW YORK.

THE nature of the so-called tendon phenomena has been a subject of discussion since Erb and Westphal called attention to their clinical significance. Authorities are divided now as they were then into those who, following the lead of Erb, regard tendon-jerks as a true reflex phenomenon, and those who, accepting Westphal's teaching, hold that tendon phenomena are expressions of the so-called muscle tonus—the latter being itself a reflex phenomenon.

At the present day the majority inclines to the latter belief. The objection still offered to a unanimous acceptation of this view is the fact that increase of the reflexes is occasionally found in connection with diminished tonus. This is often encountered in cases of total transverse lesion of the cord, and sometimes in partial lesion of the cord (ataxic paraplegia, transverse myelitis). In cerebral lesions this is illustrated by the late appearance or the occasional absence of contractures despite reflex exaggeration.

Clinical experience shows that there is a definite relationship between tendon phenomena and tonicity of muscles.

Examples of altered behavior of the tendon phenomenon, in cases in which there is conspicuous change of muscle tonus, are not uncommon. Increased muscle tonus (hypertonia) is, next to exaggeration of the tendon-jerks, the most constant clinical manifestation of disease of the pyramidal tracts. On the other hand, decrease of muscle tonus (hypotonia) is, next to diminution or absence of the reflexes, the most constant clinical accompaniment of disease of the posterior columns. Furthermore, disease of the primary motor or sensory neurons is usually manifested by hypotonia and diminution or absence of the tendon-jerks. All this shows that muscle tonus is concerned in the causation or manifestation of the tendon phenomena. To this empirical knowledge we bring the results of a study of muscle tonus, determined with a tonometer, and of tendon-jerks in patients upon whom tonometric measurements were made.

The tonometric measurements were made on the Achilles tendon, therefore the "reflex" phenomenon of this tendon, rather than that of the patellar tendon, was studied. This is the more fortunate, as increase and decrease of the Achilles reflex is less disputable.

The tonometer used was devised by Dr. L. J. J. Muskens of Utrecht, for measuring the tonicity of the Achilles tendon.† On working with this instrument we soon realized the fact that the values furnished by it were liable to variation depending upon the structural state of the tendon and its surroundings. For instance, the registrations of the instrument were different when such structural alteration existed as œdema of the soft parts around the ankle, induration of the skin, disease of the bones or joint of the ankle. In the estimation of tonometric values obtained from the examination of tabetic patients, it was soon discovered that when the tendon Achilles becomes so extremely relaxed that it lies in close juxtaposition to the tibia, the values registered by the apparatus are unreliable. We made tonometric measurements and observed the condition of the Achilles tendon-jerk in 230 individuals. The number of registrations was 554. All cases were examined under approximately the same conditions.

From a clinical standpoint the 230 cases were distributed as follows:

| | |
|---|---|
| Apparently healthy adults | 32 |
| Tabes | 25 |
| Organic disease of the nervous system | 33 |
| Functional nervous disease | 40 |
| Pulmonary disease (principally tuberculosis) | 70 |
| Heart disease | 12 |
| Various other chronic diseases | 18 |
| | 230 |

The tonometric values recorded in the course of this study range between 6 and 25. The low numbers on the scale denote a high state of tonus, the high numbers a low state. These values were ascertained by testing each extremity from 2 to 5 times, the averaged results giving a total of 554 tonometric registrations.

Before attempting an interpretation and analysis of the values obtained from these measurements, it is necessary to determine the range of numbers on the scale which represents the normal or physiological tonus—that is, normotonic values—and to use this as a key for the interpretation of the other values. Values ranging from 8 to 12 we have considered *hypertonic;* from 15 to 19 and upward *hypotonic:* and from 12 to 15, *normotonic.* Naturally we do not expect to find absolute values, merely those which hold good for the apparatus used. Neither should we expect to find values representing sharp and absolute divisions, but such only as indicate approximately normal tonus (normotonic values), increased tonus (hypertonic values), and diminished tonus (hypotonic values).

Let us now attempt to describe the method of procedure by which we distributed the tonometric values into the 3 classes above designated. We measured the tonicity of the Achilles tendon in 32 apparently healthy individuals. The tonometric values thus obtained fell into 1 of 3 groups: (1) A group in which the numbers on the registration scale were from 8 to 12, of which there were 6. (2) A group in which the numbers were from 15 to 19, of which there were 12. (3) A group in which the numbers were from 12 to 15, of which there were 14.

The 6 individuals constituting the first group were unusually muscular and athletic. Their muscles, it may be said, were normally in a state of hypertonia, dependent upon a plus development of the muscles, and upon vigorous exercise.

Three of the individuals of the second (hypotonic) group were above 50 years of age. They admitted having had at times trivial symptoms that might be attributed to approaching senility. Nine of them at the time of examination appeared healthy, but closer questioning revealed that they had had occasionally functional disturbances of the gastro-intestinal tract.

The third group is made up of 14 individuals in whom the tonometric values range from 12 to 15, and who, to all appearances, were practically healthy.

Assuming the foregoing to be correct, we call:

12 to 15 normotonic values,
15 to 25 hypotonic values,
8 to 12 hypertonic values.

It seems to be generally accepted that increase

*Read before the New York Neurological Society, March 3, 1903. A preliminary report on this subject was made by the writers to the American Neurological Association in May, 1900, and published in the *Journal of Nervous and Mental Diseases*, July, 1900.

†A brief description of this apparatus was published in the *Neurologisches Centralblatt*, 1899, Vol. XVIII, p. 1074. In this article Dr. Muskens utilizes the results obtained from the tonometric measurements of the inmates of the Montefiore Home, which are also the basis of this study.

of tonus and exaggeration of tendon-jerks are parallel phenomena and *vice versa*. In order to examine the validity of this belief, we have selected for separate study, from our collection of 554 tonometric registrations, those with hypertonic values and those with hypotonic values. For obvious reasons we shall exclude from this analysis the registrations of physiological hypertonia and those in which the working of the apparatus was interfered with by the above-mentioned structural impediments.

*Hypertonia.*

Hypertonic values were ascertained 78 times:

The Achilles reflex was exaggerated (ankle clonus).18 times (23 per cent.)
The Achilles reflex was absent..... 9 times (11 per cent.)
The Achilles reflex was normal.....51 times (65 per cent.)

A few words are necessary to explain these findings. In a general way it may be said that the greatest number of normal Achilles jerks was found in individuals whose tonometric registrations are about 12, *i.e.* around the upper limit of normotonic values. On the other hand the majority of those cases in which there was ankle clonus gave tonometric readings approximating the values of hypertonia, viz., 8. The reflexes were found absent on 2 occasions, in a case of syphilitic transverse myelitis, representing the clinical picture of ataxic paraplegia with invasion of the sacral cord, in which, at an other time, an ankle clonus was ascertained. In the remaining 7 instances the Achilles reflex was found absent in cases of tabes.

The hypertonia which was found to exist in the last named 7 instances was dependent either upon (1) the extreme relaxation of the tendon, or (2) upon the involuntary muscular contractions which are frequently seen in cases of tabes, and which interfere with the proper working of the apparatus. Indeed one of these cases gave, at a subsequent examination, decidedly hypotonic values.

We are justified therefore in excluding these 7 instances of hypertonia with absent tendon-jerks from the analysis. In this corrected form the table of hypertonic registrations would read thus:

Hypertonic values were ascertained 71 times:

The Achilles reflex was exaggerated (ankle clonus).18 times (25 per cent.)
The Achilles reflex was absent..... 2 times (2 per cent.)
The Achilles reflex was normal.....51 times (71 per cent.)

*Hypotonia.*

We find 269 hypotonic registrations.

The Achilles reflex was exaggerated (ankle clonus) 7 times (2 per cent.)
The Achilles reflex was absent.....55 times (20 per cent.)
The Achilles reflex was normal.....171 times (63 per cent.)
The Achilles reflex was diminished.....36 times (13 per cent.)

From the facts just cited it is seen that hypotonia is frequently associated with loss or diminution of the tendon phenomena. As we found in the hypertonic group a small percentage of registrations with lost reflexes, so do we find in this hypotonic group a small percentage of registrations with exaggerated reflexes. The large percentage of normal reflexes in the hypotonic group is easily explained on inspection of our tables by the same fact that applied to this occurrence in the hypertonic group. The largest number of registrations with normal reflexes in this group (hypotonic) was also very near the range of normotonic values, of course at the lower limit, *i.e.* near and around 15, while in the hypertonic group it was near and around 12.

A comparison of the tabulated hyper- and hypotonic findings shows the following:

1. A much greater number of hypotonic registrations. This is due to the fact that this study was made upon inmates of an institution which receives only those afflicted with chronic disease, and amongst these physiological hypertonia is not often found.

2. A large percentage of normal tendon phenomena despite the altered tonus. The explanation of this has already been suggested. The majority of registrations with normal tendon phenomena have tonometric values that approximate the normotonic area. Normal reflexes are found in the hypertonic group with values around and above 12, and in the hypotonic group above and around 15.

3. Next in frequency to the above are cases that show hypertonia and exaggerated tendon-jerks and hypotonia with absent tendon-jerks.

4. A small percentage of cases constituting an exception to the rule of the reflecto-tonic interdependence; 2 per cent. of hypertonia with absent or diminished reflexes, and 2 per cent. of hypotonia with exaggerated reflexes.

This last finding incites further study, and in prosecuting this we must digress somewhat. The term tonus is used in medicine in a two-fold sense.

1. In a general histological sense it is used to denote the state of general nutrition or succulence of the tissues. In this sense the term is applied to the muscles as well as to the other tissues of the body; thus we speak of the tone of the skin, the nerve tone, the general tone. When we use the word tonus in this sense, we call it, for the sake of brevity, *the histological tonus*.

2. In a special sense the term tonus is more exclusively applied to the tonus as muscle tonus, and is understood to represent the result of a purely neural phenomena. We propose to call this tonus the *neurogene* tonus. In physiological, and particularly in neurological, literature, it is the neurogene tonus that is meant when the word tonus is used.

In endeavoring to explain the small number (2 per cent.) of instances of disassociation between tonus and tendon phenomena, we shall consider only those cases of hypertonia and hypotonia in which the *neurogene* tone was evidently altered.

Let us, therefore, select for study those cases of organic disease of the nervous system which show marked alterations in the behavior of the tonus and tendon phenomena.

*Neurogene Hypotonia.*

The neurogene tonus was found diminished 71 times:

The Achilles reflex was exaggerated (ankle clonus). 7 times (9 per cent.)
The Achilles reflex was absent.....53 times (74 per cent.)
The Achilles reflex was normal..... 6 times (8 per cent.)
The Achilles reflex was diminished..... 5 times (7 per cent.)

In comparing this table with the table of hypotonic registrations obtained above, the following points are noted:

1. The comparatively small number of neurogene hypotonias. There are 269 examples of general hypotonia (histological and neurogene) and only 71 of neurogene hypotonia. In explanation of this it may be said that the very highest registrations of hypotonic values (from 20 to 25) are found in the neurogene group, and that a large number of hypotonias found in the general group approximate the border line of the normotonic values (15).

2. In the group of neurogene hypotonias the percentage of registrations in which there is loss or diminution of the tendon-jerks, is, on the other hand, much larger than the percentage of the same in the general group.

3. Exaggerated reflexes are much more frequent in the group of neurogene hypotonias than in the group of general hypotonia.

4. The percentage of normal reflexes is very much smaller in the cases constituting the neurogene group than in the general group. This tends to

substantiate the explanation of the comparatively small number of neurogene hypotonias given above. (No. 1).

It may, therefore, be said that neurogene hypotonia and absence or diminution of the tendon phenomena often co-exist and are parallel occurrences.

*Neurogene Hypertonia.*

The neurogene tonus was found exaggerated 28 times:

| | | |
|---|---|---|
| The Achilles reflex was exaggerated (ankle clonus) | 17 times | (60 per cent.) |
| The Achilles reflex was absent | 1 time | (3 per cent) |
| The Achilles reflex was normal | 9 times | (32 per cent.) |
| The Achilles reflex was diminished | 1 time | (3 per cent.) |

Deductions similar to those drawn from the study of hypotonias may be obtained from a study of the neurogene hypertonias. The 3 points that are impressed upon us are: (1) The comparatively small number of neurogene hypertonias. (2) The large number of instances in which there are exaggerated tendon-jerks. (3) The small number of instances in which the jerks are absent or diminished.

Therefore, from the study of the neurogene hypertonias, we conclude that neurogene hypertonia often co-exists with exaggeration of the tendon-jerks. Let us now make a comparative study of the neurogene hypo- and hypertonias.

| *Neurogene Hypotonia:* Registrations | Achilles Reflexes. normal. | exagg. | dim. | abs. |
|---|---|---|---|---|
| 71 | 6 (8 per cent) | 7 (9 per cent) | 5 (7 per cent) | 53 (74 per cent) |
| *Neurogene Hypertonia:* | | | | |
| 28 | 9 (32 per cent) | 17 (60 per cent) | 1 (3 per cent) | 1 (3 per cent) |

In looking at the above table we note the following points:

1. The largest number of registrations with corresponding changes in the behavior of the tendon phenomena, *i.e.* 81 per cent. of diminished and absent tendon phenomena in the hypotonias, and 60 per cent. of exaggerated tendon phenomena with hypertonia. Evidently the influence of a diminished muscle tonus upon the tendon phenomena is more marked than the influence of an increased tonus (81 per cent. against 60 per cent.). Whether the fact that pure lesions of the posterior columns are more frequent than pure lesions of the pyramidal tracts, is an explanation of this disproportion, is an open question.

2. Eight per cent. of hypotonias show normal reflexes against 32 per cent. of hypertonias with normal reflexes.

3. About an equal percentage of divergent changes in reflexes and tonus. Nine per cent. of exaggerated reflexes in hypotonia and about 6 per cent. of diminished or absent reflexes in hypertonia.

It now remains to attempt an explanation of this last point which seems to contradict the general belief in the interdependence of tonus and reflexes.

Absent or diminished reflexes, in spite of the increase of the muscle tonus, were found in one instance, and the explanation was given above (lumbar sacral myelitis). We remarked at the outset that the belief in the absolute interdependence of tonus and reflexes is particularly weakened by the occurrence of reflex exaggeration in conjunction with hypotonia.

In the group of neurogene hypotonias, exaggerated tendon phenomena were present in 9 per cent. of the registrations. Further study of this fact shows that hypotonia was ascertained three times in cases of cerebral disease and twice in cases of spinal disease. The 3 instances of cerebral disease in which hypotonia was ascertained were cases of extensive cortical lesions substantiated by autopsy. The lesion in the 2 cases was not confined strictly to the motor area; it encroached upon the cortical sensory areas as well.

Hypotonia and exaggerated tendon-jerks were further found in 3 cases of spinal cord disease. In these cases there was clinical evidence not only of disease of both the motor and sensory tracts, but there were also trophic manifestations (muscular atrophy) indicating involvement of the anterior gray matter of the cord.

From the foregoing we receive the suggestion that an analysis of our tables, from a purely anatomical standpoint, might possibly shed more light upon this mooted point.

*Cases of Tabes* (Lesions of posterior columns).—We examined 25 cases of tabes and registered their tonometric value 61 times. If we eliminate from the analysis those values, which evidently do not comply with the requirements necessary for the reliable working of the apparatus, we must throw out 6 examinations, leaving 55 examinations to discuss. Amongst these 55 we find:

| | *Achilles Jerk.* | | | |
|---|---|---|---|---|
| Hypotonic values 50 times, or 90 per cent. | | | | |
| Hypertonic value, once, or 2 per cent... | normal. | exagg. | diminished. | abs. |
| Normotonic values 4 times, or 8 per cent.. | ..... | ..... | 6 (10 per cent) | 49 (89 per cent) |

From this it appears that lesion of the posterior columns leads almost invariably to diminution of tonus and diminution or loss of the tendon phenomenon.

*Lesions of the Pyramidal Bundle.*—It has already been said that uncomplicated disease of the pyramidal tracts is of very rare occurrence. In fact the occurrence of a primary lateral sclerosis is doubted by some neurologists. It ought, further, to be borne in mind that modern neuropathology has demonstrated more than one central motor tract. At present the following 5 tracts are supposed to carry motor influences to the cord: (1) The pyramidal tract. (2) Monakow's bundle, leading from the red nucleus to the contralateral lateral column. (3) A tract leading from the quadrigeminal bodies to the contralateral anterior tract. (4) Tracts leading from the pons to the homo or contralateral, anterior, or lateral tract. (5) A tract leading from Deiter's nucleus to the ventral zone of the anterior tract.

It is evident that when the pyramidal tracts are commonly spoken of, it is not clearly stated which one of the tracts is meant. In our list one case of apparent primary lateral sclerosis is found. It is a case which presented, clinically, evidences of considerable spasticity with fibrillary twitchings of the muscles, without atrophy and without trace of sensory disturbances. In this case 2 tonometric examinations showed hypertonic values and exaggerated tendon-jerks.

As it is not legitimate to draw conclusions from but one case, we shall therefore approach the question from another standpoint and single out from the cases of organic nervous disease those in which there is clinical or anatomical evidence of disease of the pyramidal columns only. We consider spasticity without sensory or trophic disturbances to be clinical evidence of pure lesion of the pyramidal tracts.

It is needless to say again that only those cases to which the apparatus could be applied without difficulty are included in this analysis. It will expedite our efforts to consider these cases in 2 groups: a spinal and a cerebral group.

*Spinal Group.*

In this group we find 7 instances in which tonometric examinations were made.

Hypertonic values were obtained in 17 instances. Normotonic values in 1 instance (the exact registration in this instance was 13, just above the limit of hypertonic values).

From these 18 examinations the tendon-jerks were found:

| Normal. | Exaggerated. | Diminished. | Absent. |
|---|---|---|---|
| 5.11 per cent. | 16.88 per cent. | ..... | ..... |

From this the inference is justifiable that hypertonia produced by disease of the spinal section of the pyramidal tract is always associated with hyperactivity of the tendon phenomena.

Therefore the inference is justifiable that hypertonia produced by disease of the spinal section of the pyramidal tracts is always associated with hyperactivity of the tendon phenomena.

(2) *Cerebral Group.*

This group is made up of 17 cases with 36 tonometric registrations. In 8 of these the diagnosis was verified by autopsy and showed: (1) Two cases of meningoencephalitis with little damage to the motor area, normotonic values, no ankle clonus. (2) One case of extensive cortical and subcortical disease of the brain with normotonic values approaching the hypotonic border and exaggeration of the tendon phenomena. (3) One case with lesion of general paresis with little damage to the motor area, normotonic values, no ankle clonus. (4) Two cases of cortical encephalomalacia of motor area with markedly hypotonic values and ankle clonus. (5) One case of extended cortico-subcortical lesion, the latter more pronounced than the former, with normotonic values and ankle clonus. (6) One case of tumor in the left ponto-cerebellar angle. In this case there were hypotonic values and absent tendon phenomena on the right side, hypertonic values, and an occasional ankle clonus on the left side.

In the 9 remaining cases of cerebral disease we have to rely upon the clinical evidence only and we find: Three cases of evidently subcortical lesions with hypertonia and ankle clonus. One case of evidently cortical disease with hypotonia and normal reflexes. One case of chronic hydrocephalus with hypertonia and normal reflexes. This case is not suitable for analysis, because this hypertonia was manifestly one we call physiological hypertonia. One case of multiple sclerosis in which the examination could not be made reliably. Three cases of subcortical disease with normotonic values, in which there was in one an ankle clonus and in two no exaggeration of the reflexes.

From all the cases of the cerebral group we can evidently choose for our discussion only those in which there is: (1) Disease of the motor tract. (2) Those in which the apparatus worked without difficulties.

With these restrictions we find in the cerebral group: Two cases of cortical invasion of the motor area with hypotonia and exaggeration of the reflexes. Three cases of subcortical lesions with hypertonia and exaggerated reflexes. Three cases of subcortical disease with normotonic values, in two of which were normal reflexes, in one exaggerated reflexes.

Among the last-named 3 cases there were 2 in which there was scarcely any paralysis, therefore scarcely any permanent damage to the motor tracts, and in these 2 cases the tendon phenomena were normal. The third case showed more paralysis and also ankle clonus. It is further seen, from an analysis of the cerebral group, that uncomplicated disease of the pyramidal tracts is much less frequently cerebral than spinal. It is upon this point in particular that the whole discussion of the interdependence between tonus and reflexes is carried on. The authorities who believe in the absolute interdependence of the second phenomena explain the familiar clinical facts of the late appearance of contractures in cerebral lesions, and their occasional absence in transverse lesions of the cord, by a hypothetical inhibitory irritation. Others who deny any such extensive interrelation between tonus and tendon phenomena, explain the stated clinical facts on anatomico-physiological grounds. (van Gehuchten.)

We do not propose to attempt to decide which view is correct, but simply to state briefly the results of our analysis of the hypertonic instances. We have seen that hypertonia produced by pure lesions of the pyramidal tracts is always coupled with exaggeration of the tendon phenomena.

When, in addition to the pyramidal tracts, other tracts are involved, the tonophile influence of the diseased pyramidal fibers is neutralized by the antagonistic influence of diseased afferent fibers. For the neutralization of the reflexophile influence of diseased pyramidal fibers, apparently more extensive disease of the antagonistic fibers is necessary.

Aside from the cases that come within these two groups of organic nervous disease, we have 1 case of Friedreich's ataxia with tonometric registrations showing hypotonic values, and absent tendon phenomena, and 1 case of chronic anterior poliomyelitis (autopsy) with hypotonic values and absent tendon-jerks.

We shall now proceed to a study of the tonus in cases without organic disease of the nervous system. It is well to state at the outset that profound variation of tonus and of reflexes, such as exists in the group just studied, is not found in this group. In other words, amongst the individuals whose neurogene tonus was presumably not diseased we did not often find marked hypertonic values (6–9), or marked hypotonic values (20–25). At no time did we ascertain undeniable increase or undeniable absence of the tendon phenomena. The tendon phenomena were found lively, normal or diminished, and the tonometric values ranged between 11 and 20.

Thus we are enabled to outline further differentiation between what we call histological tonus and special or neurogene (muscle) tonus. We have learned that whenever the neurogene tonus alone is markedly increased or decreased, the tendon-jerks are increased or decreased correspondingly. Alterations of the histological tonus and of the tendon phenomena are not so marked. The fact of a mutual modifying influence of both neurogene and histological hypo- and hypertonia upon the tendon phenomena is, of course, to be borne in mind.

The conclusions reached are in brief as follows:

1. Disease of the posterior columns causes hypotonia and decrease of reflexes. When these conditions are present, the tendon phenomena are absent or diminished unless additional disease of the descending tracts counterbalance this influence. (Return of knee-jerks in cases of tabes after hemiplegic attacks.)

2. That disease of the pyramidal tracts causes hypertonia and increase of reflexes. The tendon-jerks under such conditions are increased unless additional disease of the ascending tracts, anterior horns or peripheral neurons neutralizes this influence.

3. Histological hyper- and hypotonia modify the above-stated relations to a slight degree when

the disease has not advanced to its full clinical representation.

4. We find in our lists a large group of more or less normotonic registrations with approximately normal behavior of the tendon phenomena.

5. We find a smaller group with more or less marked hypotonic registrations. In this group the tendon phenomena are mostly diminished. This diminution is evidenced by the fact that the tendon-jerks are not easily elicited, that the muscular contraction is sluggish and vermicular, and is easily exhausted. It is well to state here that the above mentioned behavior of the tendon phenomena is not influenced by a well-executed reinforcement.

## A RARE CASE OF PATENT DIVERTICULUM ILEI.

By AUGUST ADRIAN STRASSER, M.D.,
ARLINGTON, N. J.

John W., born April 19, 1903, after a normal gestation and physiological partus. fourth issue of perfectly healthy parents. The child was normal in every respect except the following anomaly:

While the normally implanted cord was being tied, there was seen in its inferior aspect, at its junction with the umbilical ring, a triangular slit about 2 cm. long, through which protruded a dark purplish-red tumor about the size of a small cherry; in the summit of this there was an opening, from which, with the straining incidental to crying, there issued in jets small amounts of meconium. This, after twenty-four hours, after the bowels had moved normally by the anus, changed in character to the ordinary yellow fæces of the healthy babe.

The child nursed well and scrupulous care was exercised to keep the skin around the umbilicus as clean and aseptic as possible. There was a very slow detachment of the cord; it came off on the eleventh day, leaving a clean scar. The protruding diverticulum of the bowel was then about the size of a raspberry. Under the use of a powder of boric acid and bismuth subnitrate and very firm compression, there was not only a reduction in the size of the tumor, but also a cessation of the discharge of fæces from the fistulous opening, so that for a time it seemed to promise a spontaneous cure. But a month later it grew larger again and a slight fecal discharge reappeared.

The reason I report the case is its great rarity. The literature on intestinal anomalies is not voluminous. Congenital umbilical hernia is rare; still more so is that abnormal condition in which the lower portion of the gut from the omphalomesenteric duct to the sigmoid is obliterated and the anus imperforate. Cases of this kind usually present other malformations also. But the rarest condition of all is the one described above. In a careful search of the literature I have been able to add to the thirty-nine cases reported by Morian and the four cases reported by Hubbard, twenty-one cases, including my own, that were overlooked or reported since Hubbard's article was written.

The table on page 934 includes the cases so far reported; but several of them are doubtful; others are cases of prolapse of Meckel's diverticulum without patency; and still others Tillmann looks upon as cases of artificial anus produced by accidental tying of the bowels; and for that reason such cases, for instance, as Schneider's, Stadfeldt's, Thudichum's, Latimer's, and Motte's are not included in the table; but Marshall's and Jacoby's are retained because they make part of Morian's table, and I have added Broadbent's because he reports his case as one of umbilical fecal fistula in the new-born, and as it is, in my opinion, a true case. I have also not included such cases as MacSwiney's, Bottini's, and Nicholich's, in which the patency was discovered only by the fact that ascarides used this tract as a means of egress, or which were only cases of persistent Meckel's diverticulum.

*Anatomy of the Anomaly.*—Its occurrence takes us back to the third or fourth week of embryonal life. In the embryo of the third week, the rudimentary fore-, mid-, and hind-guts are visible. The primitive mid-gut is connected at this period of embryonal life by a tubular canal, the vitelline duct, with the yolk-sac. The embryo lies curved over this yolk-sac with its endodermic surface spread out. Then as the cephalic and caudal extremities curl up, and the sides fold in, differentiation commences and the embryo is gradually lifted from but still attached to the yolk-sac by the yolk-stalk. At the fourth week the sac has begun to atrophy and the duct is only a very thin canal; by the fifth week the navel closes entirely and the omphalomesenteric duct is obliterated. In the sixth or seventh week the loop of intestine, which may be in the cord, is withdrawn and the intestines now lie free in the abdominal cavity. If this normal process is interrupted, various malformations result from the persistence of part or all of the vitelline duct.

Riesman (*Univ. Med. Mag.*, 1897–8, X, p. 526–539) classifies these as follows: (1) Persistence of the proximal portion of the duct—Meckel's diverticulum; (2) Persistence of the entire duct as a patulous canal; (3) Persistence of the distal part of the duct connecting with the navel; (4) Persistence of the middle of the duct; (5) Persistence of the omphalomesenteric vessels.

The cases under discussion come under the second heading of this classification; examples of the other forms are constantly reported in surgical literature, where their presence is no longer recognized as a rarity. The usual site of implantation of this diverticulum is on the ileum, anywhere from the ileocæcal valve of Bauhin to 58 cm. above it, and is varies slightly in length, but is never above 8 cm. long.

*Sex.*—The subjects of these anomalies are predominently of the male sex. In thirty-nine cases in which the sex is given, only five were of females.

*Age.*—Of course to be counted a true case of patent diverticulum ilei, the case should have been observed directly at or soon after birth. Many in the table were. Foerster's case, however, was in a woman, aged thirty-four, who came to necropsy, when the condition was discovered. Evidence by relatives proved the condition congenital; it had persisted until death, for colored food—berry-juice, etc.—had always stained the discharge.

The presence of the condition at birth and even finding meconium extruded before the cord was tied, removes all doubt as to the fetal origin of my case.

*Presence of Other Malformations.*—Unlike malformations of other parts of the gut, such as absence of the colon and imperforate anus, which are usually associated with other anomalies like harelip, cleft palate, spina bifida, exstrophy of the bladder, absence or defect of long bones, congenital dislocations, club feet, and genital defects, this condition occurs only in apparently otherwise normally developed children. Only Escherich's case (63) showed additional deformities (defect of radius and sacrum, caput obstipum, congenital hip dislocation, club-feet); but as he mentions no fecal discharge from the opening of the diverticulum, the case may have been one of persistence of the distal part of the duct (Riesman's third heading).

*Complications.*—In a number of cases reported, various complications occurred. Both Golding

Bird's and Barth's cases are reported as intussusceptions of the gut into patent Meckel's diverticula. Other forms of intestinal obstruction are always to be watched for. In Nicholas' case there were futile attempts at reposition. Another danger is the possibility of hemorrhage. This in two cases was sufficiently alarming to deserve attention. There is no difficulty with the feeding of these children; they all seem to thrive. Only in Heaton's second case was the emaciation extreme on admission to the hospital.

*Diagnosis.*—The presence of a dark purplish-red tumor at the umbilical opening, varying in size, not painful to the touch, covered by mucous membrane which bleeds readily, becoming tense when the child cries, and in which there is an opening whence meconium or fecal matter is discharged, makes the diagnosis of the diverticulum ilei reasonably certain. The presence of a fecal fistula at the umbilicus, or even a persistent opening there is suspicious; and Barth correctly advises careful scrutiny of every case of umbilical granuloma to discover a possible diverticulum; and if such is found, the introduction of a fine catheter serves to establish its patency and connection with the gut, if fæces are withdrawn in the eye of the instrument. This may be so minute in quantity that only microscopical examination establishes its identity. Tillmann's case of ectropia ventriculi is so far unique. In this case there was a gastric diverticulum—a prolapse of the gastric mucous membrane through the umbilical ring.

*Prognosis.*—For the condition itself the prognosis is very good. Most of the deaths in the recorded cases were in pre-Listerian times; and those of the later years were in moribund subjects or found at necropsies. Under aseptic treatment, operative or otherwise, the majority of cases recovered and remained well. Ledderhose's monograph on the subject unqualifiedly gives a good prognosis.

*Treatment.*—The various forms of treatment present almost equal rates of mortality. The ideal operation, of course, is excision, resection, suture of intestines, and suture of umbilicus.

*Conclusions.*—The following conclusions are warranted: (1) The condition is one of great rarity; (2) Males are more frequently afflicted; (3) Careful attention should be paid to any granulations at the navel, before and after the dropping of the cord; (4) It will be wise at all times to remember the possibility of an included bowel and tie the cord at least two inches from the umbilical ring; (5) A radical operation is safest, to do away with the possibility of intestinal obstruction through diverticula later in life.

**Herpes Tonsurans.**—Bundt had observed several cases of herpes tonsurans, the origin of which he traced to the disease in a young bull. To avoid such a contagion he advises: (1) The prevention of transportation of infected animals. (2) Isolation of such animals. (3) Very careful cleansing of the caretakers of these animals.—*Zeitschrift fur medicinische Beamte.*

## THE TREATMENT OF CANCER BY CAUSTIC PASTE.

BY CHARLES WARRENNE ALLEN, M.D.,
NEW YORK.

IN a series of reprints just received under the title of "*Radiotherapy*," which includes articles published in the MEDICAL RECORD, *The Journal of the American Medical Association*, *The Inter-State Medical Journal*, and the *Medical Mirror*, Dr. A. Campbell White of this city makes, in one of the papers, the following statement, which I think should not be allowed to go unchallenged. He says: "The caustic treatment in the form of injections, pastes, and all other kinds of mixtures, rarely prove of any service, and usually only deceive and render more uncomfortable the existence of a patient. They have been discarded by almost all except charlatans."

While it is quite true that treatment by arsenical paste, which once had quite a vogue, became much neglected by reputable physicians, although charlatan cancer-curers continued to use such application, the disrepute into which they fell was due largely to the attempt on the part of these ignorant and untrustworthy persons to extend the treatment to deep-seated, extensive, and unsuitable cases. For a quarter of a century I have made a practice of applying arsenical and other caustic pastes to various forms of epithelioma, especially about the face and often in regions which were inaccessible or unsuitable for successful knife surgery.

Believing that Dr. White does not mean to class me amongst the charlatans, I must come under the other class of the few who persist in this method of treatment. That there are many others both in this country and abroad who recognize the great value of the method and must be classed with the reputable members of the profession goes without saying. An ardent advocate in this city, whom I have the honor to number among my dermatological colleagues and friends, who has done much to advance the paste-treatment, may be mentioned, Dr. A. R. Robinson. Teaching as he does at one of our post-graduate schools, and I at another, never omitting an opportunity to advocate what we believe to be a superior form of treatment for many forms of cancer, it must follow that throughout the length and breadth of this country there are many reputable physicians curing epithelioma in this way whom Dr. White would not desire to designate as quacks.

Liquid air, the *x*-ray, the Finsen light, all have their use and advantages, and radium may soon be proven their equal or superior; but for the majority of practitioners these methods are not available. In answer to Dr. White's claim that caustic methods are painful and add to the patient's suffering without subsequent commensurate benefits, I wish to take advantage of this opportunity once again to put forward the painless method of my own device which I have practised for a number of years with the utmost satisfaction; I refer to the plan of making the arsenical paste with orthoform, the analgesic qualities of which drug exert their influence *pari-passu* with the painful effects of the arsenic on the tissues and nerves. Either cancer is becoming more prevalent or more patients are coming under early observation and treatment, and it is only due to the profession and the public to know that in some forms a cure can be effected, in the early stages at least, promptly and painlessly, and that advertising charlatans are not the only ones who cure these forms without the knife.

In looking over my statistics of epithelioma

treated before the days of *x*-ray, and comparing the results with those following *x*-ray treatment, I was struck with the little difference to be discovered. Comparing fifty cases treated by pastes alone with fifty patients who had the benefit of the *x*-ray in addition or as the sole method employed, the final results, number of recurrences, etc., were almost identical. I cannot now give the exact figures, as the table is in the printer's hands but will soon appear in book form.

Since the above was written I have opened the last volume, recenty received, of *Progressive Medicine*, and find on page 127 a quotation from some of my own writings in Dr. Gottheil's really excellent review of dermatology and syphilis. He does me the honor to say: "Allen's conclusions represent the position that seems rational, and as they summarize our present knowledge upon the subject, I repeat them:

"1. Cutaneous cancer is traceable in almost all cases to preceding local irritation.

"2. There may be other causes, but infection is probably a source of the disease.

"3. Benign epitheliomatous proliferation may be infectious.

"4. Cancer is curable, but if the disease is allowed to progress the patient may not be.

"5. Only the most radical treatment is to be tolerated.

"6. Caustic paste, with subsequent caustic dressing, is radical, and is often preferable to the knife.

"7. The earlier cancer is treated the less likelihood is there of relapses or metastases.

"8. The *x*-ray bids fair to be as effective as caustics."

With this added strong authority for the use of caustics it would seem that writers should refrain from referring to the method as one leaning toward charalatanism.

30 East Thirty-third Street.

---

**The Origin of Malignant Neoplasms.**—F. de Quervain says that experimentation so far has shown that the existence of a parasite of cancer is not yet proved, and that clinical and experimental researches up to the present have only succeeded in establishing the inoculability of cancer by a "cellular graft," and not by a virus, outside living cancer cells. The theory of the parasitic origin of cancer, instead of explaining away all difficulties, gives rise to many new problems which are as difficult to solve as the development of a malignant tumor without the intervention of a microorganism. The search must be continued, but by means of experiments from animal to animal, and not from man to animal. This should be easy enough, because cancer is common in dogs and mice. First of all, one ought to find out whether cancer is transmissible by the cancerous juice, rigorously excluding in these experiments the transplantation of cancer cells. If one could thus discover the vehicle of the virus, it would make it less difficult to determine its nature.—*Medical Press and Circular.*

**Clinical and Pathological Observations of Joint Mice.**—Boerner reports observations in nineteen cases of this condition. His classification embraces: (1) Joint mice containing microscopical evidence of origin from articular surfaces and not of gouty nature. These may or may not give a history of trauma. (2) Joint mice which do not contain articular cartilage, but are excrescences produced in consequence of arthritis deformans. Microscopical examination of preparations showed that healthy cartilage was but rarely present, more or less pronounced necrosis being found even in bodies of recent origin. No relationship appeared to exist between the age of the movable body and the regressive changes, and it was impossible to find any explanation for their variations in different cases. No differences were observed between traumatic and non-traumatic cases, and evidence of inflammatory processes could not be detected. In regard to the mode of origin of such bodies, the author believes that they may be produced by gradual separation from the articular surfaces. A partially loosened body may remain for years in its hollow and give rise to symptoms of varying severity, its final separation being due to mechanical causes. No evidence of the existence of such a clinical entity as osteochondritis dissecons, supposed by some to be concerned in the production of these bodies, could be discovered.—*Deutsche Zeitschrift für Chirurgie*, Vol LXX, Nos. 3 and 4.

**Injections of Camphorated Oil in Pulmonary Tuberculosis.**—E. Nienhaus treated seventeen patients with subcutaneous injections of camphorated oil after the method of Alexander. The injections were given either daily (0.3 g. of 10 per cent. camphorated oil), or 0.1 g. of camphor was given daily for four days, then an intermission of eight days, four days of treatment, etc. It was found that the injections were well borne and never produced any disturbances of the general condition. Its action, however, is merely that of a heart stimulant, and it has no direct effect on the local pulmonary condition. The blood-pressure is not raised by the treatment, neither is the temperature influenced. The injections are of value in strengthening a heart severely poisoned by advanced disease, and in this way prolong life, though large doses must be used. Hemorrhage is a contraindication.—*Zeitschrift für Tuberkulose und Heilstattenwesen*, Vol. V, No. 1.

**The Congeners of Phagedena and Their Treatment with Turpentine.**—George Ross recalls a story of the early days of his practice, when gangrene threatened the life of a hospital patient, and nothing seemed of any avail to check it. A prominent physician gave the advice to mop the sloughing mass to saturation with pure spirits of turpentine, cover with a dressing, and give the patient a teaspoonful of the drug every two hours. At the end of forty-eight hours the slough had fallen out, leaving a granulating surface, red as a beefsteak, and the patient was on the high road to recovery. Another case of sloughing ulcers on the calf of a man's leg was treated in the same way and promptly cured, and the same result followed in a case of hospital gangrene involving almost the whole of the gluteal region of one side Pure spirits of turpentine, locally applied to fresh cut or foul sore, is Nature's perfected detroyer of germ-life—the ideal non-corrosive, innocuous disinfectant, and, when administered internally, save and except only adrenalin chloride, the product of the suprarenal capsules is the most efficient capillary astringent known.—*The Railway Surgeon.*

**Phthisis in Relation to Life Insurance.**—T. D. Lister states that the normal danger to the office arising from phthisis is made up of three factors: Inherited vulnerability, largely diminished after middle life, *i.e.* decreasing with age. Acquired vulnerability increasing with age. Infection, equally likely at all ages. The sum of these three factors causes the normal danger from phthisis to be the same at all ages, but as age advances the percentage of deaths from phthisis out of the total number of deaths diminishes with growing rapidity, owing to the larger number of other causes of death which occur in the later years. All additions for any extra risk from phthisis must, therefore, be larger in early life, but especially so with the danger decreasing with age. An excessive danger from phthisis may be inferred in an individual when he has inherited vulnerability, acquired vulnerability, or a risk of infection (or two of these) in a degree greater than average healthy members of his own class. Personal condition is an important factor in determining this degree.—*The Practitioner.*

## THE BORDERLAND OF DIPHTHERIA AND SCARLET FEVER.

A RECENT paper by H. E. J. Bliss in *The Lancet* discusses this question from a broad standpoint. The author comments on the rigid nosology of the present day, which, he says, is a period dedicated rather to the apotheosis of the systematist rather than to the philosophical contemplation of morbid phenomena. He states his desire to discuss the conditions that lie between those aggregations of morbid symptoms which we call, for convenience sake, scarlet fever and diphtheria. These are diseases, he says, which resemble now one of the two and now the other, but yet fade away to a sort of neutral zone, leaving us in doubt as to the exact category under which they ought to be placed. A similar illustration is the so-called "fourth" disease of the measles-rötheln-scarlet fever group.

The only justification for the creation of a new disease is the erection of a fresh and sufficiently distinctive criterion to which reference may be made in cases of doubt. Such criteria are constantly shifting their ground as our knowledge increases. Absolute truth is merely an ideal and not an attainable finality. As a matter of fact, diphtheria, scarlet fever, and tonsillitis, using those terms in their broadest sense, afford many examples of departure from their respective types, and at times insensibly merge one into another.

Various forms of tonsillitis present rashes, and the author calls attention to the necessity in every case of sore throat of making a routine examination of the skin. He states that he has been vividly impressed with the frequency with which erythemata of all kinds, shapes, and distributions occur in these circumstances. From a little mottling of the chest to the most intense general blush such rashes vary, and over and over again scarlet fever has been suspected where it did not exist. On the other hand, it is quite possible that many of these cases have been mild ones of scarlet fever in which the diagnosis has never been cleared up. The distinction is not possible with our present equipment. Another confusing class of cases is made up of sore throats attended with deep ulcerations. They are not frankly diphtheria or scarlet fever, but they run a severe course and are occasionally fatal. Their chief feature is the presence of a large ulcer or ulcers on the tonsils and surrounding tissues, some of considerable extent and depth; the adjacent lymph glands are inflamed, and there are fever and general constitutional disturbance. The local process sometimes leads to considerable destruction of the throat tissues, and the system may become infected by the pyogenic cocci. The great difficulty at first is the distinction of these cases clinically from diphtheria which they resemble strongly in the throat appearances; when this difficulty is disposed of by the progress of the case the suspicion of scarlet fever begins and is often, indeed, present to the end, so similar are the later lesions of the fauces and palate. The general symptoms, too, are of the sthenic type—delirium, restlessness, and considerable pyrexia—which suggest a much closer relationship to the latter disease than to the adynamic, algid diphtheria.

Bliss believes that an actual coincidence of diphtheria and scarlet fever is very rare. One may overlap the other, that is, the symptoms of one may appear and progress while the symptoms of the other are fading away. He relates several clinical histories illustrative of the various points made in his paper, and while emphatically discountenancing vagueness in diagnosis, recognizes that there may be cases in regard to which equally competent men may differ. The bacteriological test is not absolute, for as diphtheria bacilli are found in the throats of healthy persons, so also they may be found in the throats of scarlet fever patients; and their mere presence does not justify the diagnosis of diphtheria. The fact remains then that the shadings between these two diseases and some of the severe forms of tonsillitis are so gentle that each shades off into the other not at one but at many points, and whilst this continues to be so, with the most consummate skill and the widest experience, the diagnostician can never attain a certainty in his art which its inherent disabilities forbid.

## HISTORY OF MARITIME QUARANTINE IN LOUISIANA AGAINST YELLOW FEVER.

DR. QUITMAN KOHNKE, Chairman of the Board of Health and Health Officer of the City of New Orleans, read a paper on the above subject before the Louisiana State Medical Society, April 28-30, 1903.

Quarantine for New Orleans was first suggested by W. C. C. Clairborne in 1810, but it was not until 1816 and 1817 that the City and State authorities first enacted quarantine laws. In 1819 the Legislature repealed all existing quarantine laws, abolished the Board of Health at New Orleans, and vested in the governor the power to proclaim quarantine. In 1821 quarantine laws were reënacted, and a Board of Health composed of twelve members was appointed; but in 1825 all quarantine laws were repealed. For sixteen years there was no Board of Health, and it was not until 1841 that a Board of Health was reëstablished. In 1853 and 1854, owing to the prevalence of yellow fever, the Legislature reënacted quarantine laws. The measures then enforced were: Detention of ten days in quarantine, during the summer months, of vessels from tropical zones; removal to hospitals on shore of persons found sick on board; and a superficial cleansing of vessels excessively filthy.

In 1867 disinfection of premises by carbolic acid was suggested and practised by Dr. S. E. Smith, President of the Board of Health, and in 1873 Dr. C. B. White, President of the Board of Health, encouraged by the apparent success attending the use of disinfection about premises, recommended

disinfection of ships and cargoes in addition to the prescribed ten days' detention in quarantine.

In 1874 special efforts were made in the direction of disinfection. By the aid of an apparatus designed by Dr. Alfred W. Perry, quarantine physician at the Mississippi Station, sulphurous acid gas in large quantities was forced into the holds of vessels, carbolic acid being still used freely above deck. During the time that Dr. Perry was in charge of the quarantine station—about six months—no yellow fever developed on ships disinfected by him, although several had arrived with yellow fever on board. Two days after the station came under the charge of Dr. Perry's successor a vessel from Cuba was passed without disinfection, and a week after yellow fever broke out on the vessel. In 1876 detention of vessels in quarantine was omitted, and reliance was placed solely on inspection and disinfection.

The epidemic of 1878, thinks Dr. Kohnke, was the last one caused by personally conveyed infection, for the precautions taken against infection since then have been and are such as to exclude with a reasonable certainty infected persons. As regards infected mosquitos, however, the case has been different. The fruit-carrying trade had developed into one of great importance, and vessels carrying fruit, and incidentally infected mosquitos, could not be subjected to sulphur fumigation. In 1886 the privilege of entry without detention was extended to the fruit trade under the following stipulated conditions: The avoidance of infected ports; the employment of acclimated crews; and the non-acceptance of passengers during the summer months. After discharge of the cargo the empty hold of the vessel was fumigated with sulphur. In 1886, also, Dr. Holt had built, for the better disinfection of clothing, a heating chamber. In 1895 the quarantine authorities passed a resolution abolishing the fumigation of the empty holds of fruit vessels maintained in a cleanly and good sanitary condition and running only to known healthy ports. In 1897 and in 1898 yellow fever was introduced by some means into New Orleans, and Dr. Kohnke is of the opinion that it is not illogical to suggest that these means were infected mosquitos brought in by incoming fruit vessels from infected ports.

In April, 1903, an appeal was addressed to the quarantine authorities to restore the sulphur disinfection of the empty holds of all fruiters, instead of limiting this measure to vessels from known infected ports. This appeal was referred to a committee of the State Board of Health, and is now under consideration.

Meanwhile the conditions are these: Vessels (other than fruiters) from tropical ports from which yellow fever may be imported, are disinfected entirely before admission; passengers being detained with the vessel to complete the full period of incubation (five days) after such disinfection. Fruiters from infected ports are disinfected, except the hold and cargo, and admitted without detention, the empty hold being disinfected with sulphur, burned in iron pots after discharge of cargo. Fruiters from ports not considered infected are disinfected partially only, the hold and cargo being not included, and are admitted without detention. Fruiters containing cases of yellow fever are detained for five days after disinfection. Fruiters may send their cargoes to the city on lighters previous to disinfection of the vessels.

Dr. Kohnke deduces from the foregoing facts these conclusions: That even a superficial reading of history compels us to recognize the two cardinal principles of quarantine against yellow fever—destruction of mosquitos and detention for five days of persons exposed to the disease. He likewise holds that if there be a proper field for experimentation it must be somewhere in the uncertain realm of fomites. "There is," he says, "much to discover in this field, for there is little known, perhaps less to be learned, save in a negative way."

## THE OVERLAYING OF INFANTS.

In the last ten years England and Wales were deprived of 15,009 infants through their being suffocated in bed by their parents or nurses. His Majesty's coroner for N. E. London, William Wynn Westcott, states in the *British Medical Journal* of November 7, 1903, that in the year 1900 alone there were 1774 cases, and that in Liverpool during one year more than one in seven of all inquests upon children were shown to have been made necessary by this form of suffocation. Unlike many statistics, it is probable that these show an actual underrating of existing conditions for the simple reason that a diagnosis is in many cases impossible, the parents or nurses being always ready to state that the child had convulsions or some other form of trouble immediately before death.

If the child was very young and feeble, there may be no evidence whatsoever of death, because many of these children, especially if they have drunk the milk from an inebriated mother, succumb to the simple pressure of the bedclothes or to the burying of their faces in a pillow. Three cases are recorded in which such infants have been killed by having been overlain while asleep by the domestic cat. Other cases show undoubted marks of pressure upon the body or face, of which probably that most pronounced is a flattened nose. In the sthenic class of overlain children, there may be some evidences of a struggle, and these cases are more apt to show the characteristic evidences of suffocation than the little feeble asthenic children referred to. The lips are blue, the face livid, the arms and legs flexed, the hands clinched; blood-stained froth in the nostrils and the mouth; the tongue protruded, the nails blue.

In *Casper's Forensic Medicine*, 1862, it is stated that under the old penal code of Prussia, mothers and nurses were forbidden under pain of imprisonment to have children less than two years of age sleep in bed with them. The new penal code does not contain this law, but the public prosecutor is directed to take legal proceedings against persons who suffocate infants in bed with them as "cases of manslaughter by neglect." On conviction, either a fine or imprisonment may be inflicted, and charges of murder are also possible. In France and Germany the mortality of infants, even in the great cities, from this form of suffocation is gratifyingly rare. A very direct relationship seems to exist between the amount of drunkenness in women and

this form of infantile death. A drunken mother on the Continent is almost an unknown sight. Indeed, throughout the wine-producing belt of Europe it is well known that drunkenness is rare —padded cells and delirium tremens wards being almost without exception unnecessary.

No country can afford to lose 15,000 lives in ten years—least of all England. With the increasing density of our population and a corresponding approximation of our conditions to those existing in England, it will be of interest for us to follow closely the course pursued by the British jurists in their efforts to limit this unjustifiable destruction of life.

### The Community and Tuberculosis.

A paper bearing the above title was read by Dr. Beverley Robinson of New York, before the Climatological Association, the meeting of which was held in Washington, on May 14, 1903. So much has been written and spoken concerning tuberculosis within the past few years, that necessarily addresses or papers on the subject are, to a large extent, repetitions of what has been said or penned before. Yet it is well that the matter should be constantly ventilated, in order that the public should not be allowed to subside into a state of lethargy or to relax in efforts to fight the disease.

Dr. Robinson touches upon the various methods of treatment now in vogue, but the most instructive part of his article is that which concerns itself with the home treatment of consumptives. After all, this mode of treatment is, in the nature of things, the one most largely used, and for the vast majority of people the only available treatment. As the writer points out, even if the poor could be persuaded to leave their homes and go elsewhere, there is no institution yet open to receive them. In the City of New York there is now accommodation approximately for 1,000 of her consumptive poor; there is requirement for 10,000 to 20,000 more. In all the large cities of the world the situation as regards the consumptive poor is similar to that of New York. There are thousands of consumptives who are compelled to remain at home, and who are unfortunately a menace to their family and neighbors and in a lesser degree to the community at large.

It may be taken for granted, too, that even when institutions have been built to accommodate a large number of indigent consumptives, that there will not be room for all, and that the majority must rely on home treatment. In the first instance, in this connection, it should be stated most emphatically that unless the poor are housed properly, tuberculosis will never be checked to any appreciable extent. Houses well ventilated, clean and with plenty of air and sunlight are the prime desiderata. Good well-cooked food is also a very important factor in treating the consumptive and in keeping up the resisting powers of the body against the ingress of the tubercle bacilli. The general public is as much interested in this question as the sufferers from tuberculosis and the dwellers in the tenement districts, for although the disease is only contagious under certain conditions, yet it will spread when it finds a suitable soil, and in course of time will be disseminated throughout a city. A community is notoriously selfish, and its well-to-do members are apt to disregard the plight of the poor as not directly affecting themselves.

When, however, persons of this class have been made to understand that the prevalence of tuberculosis in a city is a source of danger to everyone therein, they will begin to view the matter in a different light, and will exert themselves for their own sakes in a way that they would never dream of doing in the cause of humanity. An appeal to self-interest is generally more effectual than to rely upon the milk of human kindness, which is said to be present in all, but which too seldom flows spontaneously.

### Uncinariasis in Soldiers of the United States Army.

Dr. Charles F. Craig, in the *Journal of Medical Sciences*, November, gives the history of twelve cases of this disease which came under his notice at the Army General Hospital at San Francisco. All of the cases observed occurred in soldiers returned from the Philippine Islands, and were infected with the old-world hookworm, *i.e.* ankylostoma duodenale, and not by the new-world hookworm discovered by Stiles, and which has been described in the Medical Record.

Dr. Craig's article, instructive as it is, is too long to discuss at length, so that the methods of infection and the manner of treatment is all that will be touched upon here. As to the methods of infection, the author thinks that probably the most important are by swallowing the worms in infected food or drinking water. One very common method of infection, however, occurs in persons who handle dirt in infected localities, and because of uncleanly habits contaminate their food or convey the infection directly to the mouth with their hands. Dr. Craig makes especial mention of a method of infection which has received much study of late, that through the skin. He says: "This theory, which has now become established, was first announced by Loos. He discovered that if water containing embryos of uncinaria was placed upon the skin an itching sensation was produced, due to the worms entering the hair follicles, from which region they entered the surrounding tissues. This has been absolutely proven."

Bentley, as the result of experiments undertaken upon himself, concludes that the condition known as "ground itch," occurring in some tropical countries, is owing to infection with uncinaria. Although this has not been definitely proven it sounds probable.

The theory propounded by some authorities that the larvæ of uncinaria can reach the human being through the respiratory tract, being present in the air, according to Dr. Craig, has not received definite proof, and, so far as the present status of the case is concerned, he is of the opinion that it is not a likely means of infection.

Diagnosis of uncinaria depends almost wholly upon the finding of the ova of the parasite in the fæces.

With regard to treatment, thymol appears to be the only drug which exerts any beneficial influence on persons suffering from uncinaria. "Preventive methods," says Dr. Craig, "so far as the army is concerned, consist in the proper disposal of the excreta, careful attention to the cleanliness of the person, especially the hands, the wearing of shoes in regions in which the natives are infected, and the boiling of drinking water."

Uncinaria is a troublesome but not a deadly disease, and its course can be checked by following the rules for prevention laid down by Dr. Craig.

**Early Menstruation.**—C. Wischmann, (*Norsk Magasin for Lægeoidenskaben*) relates the case of a child aged eighteen months, in which twelve distinct menstrual periods occurred during sixteen months. Each lasted from five to ten days. The child was neither rickety nor hydrocephalic. The mammæ were large and the mons veneris was well covered with hair.

### Depopulation in France.

The *London Times* of November 5 has a short article by its Paris correspondent on the ever-decreasing birth rate of France. The communication was called forth by the publication of the reports respecting the annual contingent of recruits in France. This document once again draws the attention of the public to the depopulation of the country. Under the Second Empire, remarks the *Times'* writer, the Republicans attributed the stagnation in the birth rate to the Imperial form of government, and declared that it would increase rapidly under a Republic. This led a witty and well-known writer in the boulevard *Press*, M. Albert Wolff, to remark sarcastically that such being the case the Republicans had better change their motto of "Liberté, Egalité, Fraternité," into that of "Liberté, Egalité, Maternité." This year shows a falling off of 34,000 in the number of French recruits in contrast to a German increase of 15,000. The Minister of War, in the endeavor to check the diminishing birth rate, has accorded to married recruits and reservists the privilege of serving their time in the districts where their families reside. It is said that this privilege, which has been freely granted by the military authorities, has this year led to numerous marriages in Paris among young recruits summoned to join the colors. The remedies advocated by the extra-Parliamentary committee included administrative reforms calculated to lighten the burdens of the parents of large families, improved sanitation and hygienic arrangements to reduce the death rate among children, obligatory naturalization and a revision of the law of inheritance, diminishing the portion left to an only child, together with moral suasion and a propaganda among the peasantry against the tendency to seek employment in towns.

It is to be hoped that these measures, at least to some extent, may have the desired effect, but the canker probably lies too deep for partial remedies. The decrease in the birth rate in France has been steadily progressive, and the spirit of its inhabitants, especially of those who dwell in cities, must be radically altered ere children are born in sufficient numbers to keep the country in a foremost position. France is at present the conspicuous example of the evils attending ultra-civilization.

---

### The Biological Aspect of Infant Feeding.

The subject of artificial infant feeding has been, up to within a comparatively few years, much neglected, the teaching being confined to the clinical experience of accepted authorities. An attempt was later made to place the preparation of infants' food on a scientific basis by adjusting cow's milk so as to represent the same chemical composition and reaction as human milk. With a wider knowledge of the chemistry of milk, and more thorough comparative examinations of human milk and cows' milk, certain of their supposed differences have disappeared, and, with them, some of the accepted bases of the scientific modification of milk have also disappeared.

This should not cause, however, any reaction against scientific infant feeding. There is a scientific basis to infant feeding, which, in its essentials, is not difficult to grasp. The extended investigations into the problems of animal nutrition at the various State Experiment Stations have shown that, within certain limits, the chemical composition of food is of secondary importance, provided the food be naturally adapted to the species.

It has also been shown that by injudicious feeding the whole character of the animal body may be profoundly altered, with resulting degeneracy of the species. This disastrous effect is produced in the early stages of growth and cannot be corrected later. These discoveries have been thoughtfully considered by animal producers, and are bringing about great improvement in the physique and resisting power of domestic animals.

It is to be feared that those having charge of the feeding of infants have not altogether kept abreast of advances in the knowledge of the principles of animal nutrition, but, in view of the importance of the subject and the simplicity of the principles that have been worked out, a wider knowledge of the subject ought to be realized. In artificial infant feeding there is a biological as well as a chemical side to be considered, and the former has not been sufficiently investigated.

---

### Preventive Medicine and Natural Selection.

There are many who believe that the greater part of the philanthropic work of the world is a waste of time, money, and energy. These argue that by such means not only are persons deprived of their self-respect, but that an unhealthy stock is perpetuated, tending to a deterioration of the race. The survival of the fittest and natural selection are the battle-cries of these hardy philosophers who decry the present altruistic methods as grandmotherly in their nature.

Dr. Charles V. Chapin of Providence, R. I., contributed a paper to the Journal of the American Social Science Association of 1903 which dealt with the possible race deterioration resulting from sanitary effort. The practical point considered by the writer, was, whether, on account of the working of the law of natural selection, we are warranted in abandoning precautions against disease and permitting this law to have again a free field. Some of the reasons given by Dr. Chapin why we should not do so are as follows: So long as we are unable to exterminate the infectious diseases, natural selection must, notwithstanding all our efforts, continue to operate, though more slowly because of those efforts. Natural selection is being retarded, not eliminated. Natural selection is now a slow process, and it is difficult to say whether more suffering or death is entailed by such a process than by a more rapid one. The writer is of the opinion that we have no right to sacrifice a marked benefit in the present for the earlier realization of a hypothetical result in what at the best must be a very distant future. Dr. Chapin also thinks that infectious diseases may be completely banished long before natural selection can have established a permanent immunity.

The tendency, too, is for natural selection to lead pathogenic organisms to lose their virulence, thus becoming in the course of time merely harmless parasites. This tendency is shown by evidence both deductive and inductive. That infections are an important factor in eliminating the feeble, the poorly nourished and the constitutionally defective the writer denied, as he held that there is no evidence that they are any more susceptible to most of the communicable diseases than are the most robust. The conclusions reached by Dr. Chapin were that it appears as if natural selection in relation of man to infection is working for the ultimate good of the race; and, while public health measures are in some respects antagonistic to this process, in others they favor it. Furthermore, the immediate results of preventive measures are so marked, and the chance of overcoming these diseases in the future by other means than the immunity due to selection is so great, that we find no warrant in the principles of organic evolution for abandoning our present warfare.

The trend of existing methods of preserving human life is in the direction of prevention. The survival of the fittest by means of natural selection finds no favor in the eyes of sanitarians and physicians. In these days everyone—no matter what his physical condition may be—is to have a fair chance of an extended life. This is but reasonable, for although if natural selection were allowed to work out its ends unchecked, the evolution of a physically sound man might result, yet on the other hand brain power might be lacking. When the fact is recalled that many of the geniuses, and of the most talented and ablest, men of the world have been physically unfit. the significance of the statement will be better appreciated. *Mens sana in corpore sano*, is the ideal state, but as this high plane is beyond the reach of all, it will be better to have the mass of physical excellency leavened with the salt of brains, even though it be accompanied by decrepitude, than that the race should be composed of splendid animals handicapped by mental deficiencies.

---

### The Typhoid Epidemic at Butler.

The epidemic at Butler, Pa., is yet another object lesson on the dangers resulting from a contaminated water supply. The evidence of the majority of the physicians and citizens is to the effect that the water supply is to blame for the spread of the disease. Butler is furnished water by the Butler Water Company. Up to a short time ago the supply was taken from Conequenessing Creek, but on August 24, the dam from which the company derived its supply gave way and water was procured from a small tributary of Conequenessing Creek, known as Thorn Run. Cases of typhoid fever then began to appear in Butler, the point in dispute, however, being as to the date when the disease originated, whether before or after water was first taken from Thorn Run. Physicians also are said not to be agreed in regard to the impregnation with typhoid germs of the water of that stream. By those who hold that such was the case the claim is made that several families above Butler, who had typhoid fever, allowed their drainage to run into the river, thus infecting the water which flowed through the city.

Another theory as to the manner in which the water supply of Butler became polluted, is that it was brought about by the gangs of Italians employed in the construction of the new dam and water basin just completed. These laborers were at work on the dam for about a year, and lived as is the custom of such people in huts and dugouts, which were situated on the steep hillsides rising on either side of Thorn Run. There is said to have been no proper system of drainage for the refuse of this temporary colony, and that rain washed it down into the stream from which Butler was obtaining its water supply. Still another theory prevails to the effect that the milk supply must be regarded as the originating cause of the epidemic.

The *New York Tribune*, December 6, in an article dealing with the matter, says: "The fact that Butler's sewage drains into Conequenessing Creek has given rise to a problem which the federal authorities have deemed of sufficient importance to investigate. There are several small towns and boroughs below Butler that take their water from the Creek, and doctors agree that immediate steps must be taken to prevent the spread of the disease to these places. Dr. John F. Anderson, acting director of the hygienic laboratory of the Marine Hospital Service, has been sent to Butler from Washington to investigate the situation there and to judge of the possibility of the disease spreading to other States."

It is to be hoped that the epidemic at Butler will arouse authorities—national, State, and municipal—to the need of improving the water supply in all parts of this country. Europe is far ahead of America in this respect, and enlightened Americans cannot but feel shame that, with all its boasted advance, their country still lags behind the nations of the old world in municipal matters generally, and especially in regard to sanitation. The evidence forthcoming as to the cause of the epidemic at Butler points to the water supply as the *fons et origo* of the disease, and many cities of the United States would do well to take to heart the condition at the Pennsylvania town and resolve to set their own houses in order.

---

### The Cause and Treatment of Cancer.

Another alleged discovery of the cause of cancer has been recently added to the already long list of such happenings, and has been as usual widely heralded by the lay press. In addition to this announcement the statement is made that a specific treatment of the disease has followed as a sequence the isolation of the causative parasite. Dr. Otto Schmidt of Cologne is the author of these reputed discoveries. A striking evidence of the intense interest which is taken by the medical profession in any reported new facts concerning malignant disease, has been afforded by the despatch to Cologne of a London specialist with the view of learning all that was to be learned of Dr. Schmidt's theories and methods. On November 5 Dr. Jossé Johnson delivered an address before the Abernethian Society at St. Bartholomew's Hospital, which is reported in full in the *London Lancet*, November 14, in which he presented the result of his observations on Dr. Schmidt's specific treatment of cancer.

So far as the isolation of the parasite is concerned, it would seem that the one found by Dr. Schmidt resembles in its essential details those first described by Russell in 1890 and afterward by several investigators. But the German scientist has not offered sufficient evidence to prove clearly that he can be regarded as the discoverer of the cause of cancer.

After all, however, by far the most important part of Dr. Schmidt's statements is that in which he claims to have discovered a method of treatment which inspires the hope that at length a cure for the malady has been found.

The rationale of treatment, according to Dr. Johnson, is twofold: Firstly, active immunization —that is, by the injection of cultures, fourteen to twenty-one days old, which have been first killed by the application of heat (65°C.); and, secondly, passive immunization, by the injection of the serum of immunized animals—sheep and horses—into the subcutaneous tissues of the patient.

The result of active immunization which follows injections into the body of cancerous patients, is asserted to be a specific reaction in the tumor and affected parts. Injections of the cultures into a healthy subject or into one suffering from any other disease produced no symptoms whatever. If, on the other hand, the cancerous process is in the body, then a specific reaction supervenes, whenever there is any recuperative power in the blood of the patient. The "vaccine," in addition to its curative effects, possesses, so it is claimed, another valuable quality, one of great use in diagnosis. Although cachectic patients hardly react at all to the "vaccine," it is said that innocent growths can be accurately diagnosed from malignant ones and likewise metastatic deposits can be detected.

With regard to the action of the serum upon patients afflicted with malignant disease, the speaker was not so enthusiastic as when referring to the

results produced by the vaccine. He says it has the drawbacks of all serum injections, and that to be effective its unit value will have to be much raised.

In the discussion that followed Dr. Johnson's address the optimistic conclusions reached by the speaker were criticised, and it seemed to be the opinion of the majority of those present that these conclusions were not warranted by the evidence thus far adduced by Dr. Schmidt, and that, indeed, the public announcement of the result of his investigations was, to say the least, premature.

The MEDICAL RECORD on several occasions has deprecated the now prevalent custom of announcing as bona fide original discoveries, theories founded upon researches which have not been so thoroughly carried out as to justify a positive statement. Cancer cures are advertised in the lay press with a frequency that is both astonishing and nauseating, and any announcement such as that just made by Dr. Schmidt is seized upon by the sensational newspapers with avidity and enlarged upon and distorted with the exuberance of imagination characteristic of present-day journalists. With the distressing outcome of the publication in the lay journals of the curative effects of Koch's tuberculin, still green in the memory, no one—with such an example before him—can deny that infinite caution is needed in dealing with these matters.

## News of the Week.

**Tenement-house Conditions in New York.**—"On January 1, 1902, a new department of the city government, known as the Tenement House Department, was created. Since that time all the tenement-houses in New York have been examined and their condition ascertained. Tenement conditions, in many instances, have been found to be so bad as to be indescribable in print; vile privies and privy sinks; foul cellars full of rubbish, in many cases of garbage and decomposing fecal matter; dilapidated and dangerous stairs; plumbing pipes containing large holes emitting sewer gas throughout the houses; rooms so dark that one cannot see the people in them; cellars occupied as sleeping places; dangerous bakeries without proper protection in case of fire; pigs, goats, horses, and other animals kept in cellars; dangerous old fire-traps without fire-escapes; disease-breeding rags and junk stored in tenement-houses; halls kept dark at night, endangering the lives and safety of the occupants, and buildings without adequate water supply.

"As the result of the earnest and systematic work of the department, 40,000 buildings have been inspected, over 80,000 persons have been provided with sanitary, comfortable, and decent houses, each one of which has been built according to law; notorious evasion of, and non-compliance with, the laws has given place to their complete, uniform, and impartial enforcement; the evil of prostitution has been practically abolished in the tenement-houses; 337,246 inspections have been made; 55,055 violations filed; 21,584 repairs made to plumbing; 13,617 water-closets cleaned; 11,611 accumulations of filth removed from cellars and other parts of such buildings; 13,732 ceilings cleaned; 15,364 walls cleaned; 10,060 unsafe wooden floors removed from iron fire-escapes and new iron floors substituted; 1,701 fire-escapes erected on buildings that before were without this protection.

"The results of this work," according to the report of the commission, "are clearly reflected in the reduced death rate, which in 1902 was 18.7 as compared with 20.0 in 1901, and in the first eight months of 1903 was reduced to 18.0."

**New York Skin and Cancer Hospital.**—At the annual meeting of the Board of Governors of the New York Skin and Cancer Hospital, the following appointments were made: Dr. Willy Meyer, Consulting Surgeon; Dr. Franz J. A. Torek and Dr Wm. Seaman Bainbridge, Attending Surgeons.

**Philadelphia Hospital.**—The Association of Ex-Resident and Resident Physicians of the Philadelphia Hospital (Blockley), held their seventeenth annual banquet on December 1. Mayor Weaver; Dr. Edward Martin, Director of Public Health and Charities; Dr. G. E. de Schweinitz, and Dr. F. X. Dercum were guests of the association. Dr. J. Chalmers DaCosta acted as toastmaster, and responses were made by the Mayor, Dr. Martin, Dr. Francis J. Dever, Capt. Chas. F. Kieffer, Surgeon U. S. A., Dr. Dercum, and Dr. de Schweinitz.

**Doctor on Trial for Spreading Disease.**—Dr. D. L. Peet of Proctor, Pa., was recently placed on trial for spreading contagious disease, it being alleged that he visited patients ill of smallpox and then mingled with healthy persons, and that he also destroyed a red lamp used as a danger signal. The defence was that the disease was chickenpox and the breaking of the lamp was accidental.

**Killed on the Rail.**—Dr. Albert Blumberg of Pittsburg was killed at Braddock, Pa., on December 1, and Dr. C. Emmerling, also of Pittsburg, was injured by being struck by a train.

**Prevalence of Typhoid Fever.**—More than 1500 persons in the city of Butler, Pa., have been attacked by typhoid fever, and the State Board of Health has, after investigation, traced the source of the disease to water furnished by a local water company. During the summer, while a new dam was being constructed, it is alleged, the company pumped water from a creek near the town, in proximity to which there were a number of cases of typhoid fever.

**Typhoid Fever Prevalent in Philadelphia.**—For the week ended November 28 there were reported to the Philadelphia Bureau of Health eighty-four cases of typhoid fever from twenty-eight wards. The disease is quite evenly distributed over the city, and is generally of a mild type.

**The Home in Relation to the Tuberculosis Problem.**—The second address in the series arranged by the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis was delivered on December 3 by Dr. Wm. Osler in Philadelphia. He pointed out the importance of the home with relation to the etiology, as well as the prevention and treatment of the disease. The rarity of primary intestinal involvement and the great preponderance of bronchial and pulmonary involvement would seem to support the view of aërial infection rather than that from any other source, including milk. The ubiquity of the bacillus accounts for the prevalence of the disease, but of the large number of individuals exposed to the infection all do not suffer, and of those infected the majority recover. Not less important than the microorganism, or the seed, therefore, is the resistance or the susceptibility of the individual, or the soil. Drugs are least important in the management of the disease; fresh air and sunshine, good food and rest in the febrile cases and exercise in the non-febrile cases, are the essentials. Registration of cases is necessary for the institution of proper hygienic and prophylactic measures. Actual cure is rare; arrest of the disease is common.

**For the Extermination of Mosquitos.**—A meeting will be held in the rooms of the Board of Trade and Transportation, at Broadway and Fulton Street, New York City, on December 16, at 2.30 P.M., to consider the questions involved in mosquito extermination. The promoters of the meeting have requested all departments of health, boards of trade, village and town improvement associations, medical, entomological, engineering, and agricultural societies to send representatives, and it is hoped that a national association for mutual aid in the work of suppressing the mosquito plague may be formed. Governor Murphy of New Jersey has been invited to preside, and a number of sanitarians and other prominent men have been appointed vice-presidents. It is purposed to publish and distribute widely a full report of the papers and discussions as a means of arousing and maintaining interest in this subject. Further information relating to this meeting may be obtained by addressing Henry Clay Weeks, Esq., Bayside, L. I., N Y.

**College of Physicians of Philadelphia.**—At a stated meeting, held December 2, Dr. George Erety Shoemaker reported a case of fibrosarcoma of the abdominal wall and probably also of the pelvic organs, which has disappeared under the use of the *x*-rays. The patient was a woman, thirty-six years old, who presented a mass in the pelvis, and also involving the contiguous abdominal wall, and which, on opening the abdomen, it was found could not be entirely removed. Accordingly, treatment with the *x*-rays was instituted, with the result that the new formation was entirely dissipated. Histologic examination of a bit of removed tissue disclosed the structure of a fibrosarcoma. Dr. Arthur Van Harlingen reported a case of seborrhœa nigricans (black mask of the face). The patient was a young woman, with hysterical stigmata, who presented, on the forehead and bridge of the nose, an accumulation of sebaceous secretion, dust-pigment, and other matters out of the atmosphere, which had not been removed in several years, and gave rise to a condition rarely observed in so aggravated a form. Dr. Wm. G. Spiller and Dr. Chas. H. Frazier reported five cases of tumor of the brain with operation. They illustrated, among other things, the difficulties attending removal of infiltrating growths, and the hopelessness of permanent relief, the association of stereognostic perception with the parietal cortex, although not exclusively, and the simulation of cerebral neoplasm by tuberculosis in plaques. The surgical considerations have to do with the preparation of a suitable flap by means of chisel and mallet, trephine, electrical engine, the control of bulging of the brain at the time of operation and subsequently, and the control of hemorrhage. Dr. John K. Mitchell exhibited a specimen of intestinal sand, obtained from a neurotic male of mature years, suffering from symptoms of mucous colitis, and with a history suggestive of past appendicitis and possibly also peritonitis. A distinction must be made between true sand and false sand, the former consisting principally of calcium-salts, especially phosphate and carbonate, and the latter of elements of the food or perhaps fragments of biliary calculi or even matters introduced into the bowel for purpose of deception by hysterical or malingering patients.

**For the Daily Medical Inspection of the Public Schools.**—At a public meeting of the Public Education Association of Philadelphia, held December 3, the subject of the Medical Inspection of Schools was discussed by a number of representative speakers. His Honor, Mayor Weaver, who presided, pointed out the necessity of maintaining the health of the children in the public shools and keeping the schoolhouses in sanitary condition. Mr. Henry R. Edmunds, President of the Board of Public Education, stated that the whole body of school controllers is heartily in favor of the project. Dr. Ernst J. Lederle, Commissioner of Health of New York City, related the success of the system of medical inspection of public schools in Greater New York, and he illustrated his remarks with views of class-rooms showing the medical inspectors and school-nurses at work, as well of the city's hospitals, both established and projected, for the care of cases of contagious disease. He discussed other health measures, including open-air markets, milk inspection, meat inspection, etc., recently instituted for the better safeguarding of the entire community. He pointed out that, as the result of medical inspection in the schools, 71,229 children were excluded last year, because of various diseases. On account of overcrowding in the hospitals, additional city hospitals for the treatment of contagious diseases of the eyes, of scarlet fever, measles and smallpox, were established. Miss Lina L. Rogers, Supervising School-Nurse of New York City, spoke of the work of the corps of nurses in the public shools, and pointed out that 106 of the public schools are supplied with nurses. During the last school term of 120 days in the borough of Manhattan, 16 nurses treated 23,191 children in the school instead of sending them home. These children received 135,854 different treatments, of which 65,987 were for diseases of the eye alone; and in addition, the nurses made 7,986 visits to the homes of the school-children. Dr. Edward Martin, Director of Public Health and Charities, said it seemed the irony of fate that on the same day as the representatives of another city came to Philadelphia to recite the benefits of medical inspection in their city, the Finance Committee of Councils has reported against a similar project for the city of Philadelphia. He expressed the hope that the system would yet be established in Philadelphia, to its great advantage and benefit.

**College of Physicians of Philadelphia; Mutter Lecture on Surgical Pathology.**—Dr. C. N. B. Camac of Cornell University, College of Medicine in New York City, delivered the Mütter Lecture for 1903, December 1, his subject being, "Some Observations on Aneurysm and Arteriosclerosis." After discussing briefly the histology of the arteries, he considered the several theories that have been put forward to explain the occurrence of endarteritis, arteriosclerosis, and aneurysm. Particular importance was attached to the middle coat and its nutrient vessels in this connection, although the operation of influences acting from within the blood-stream was not ignored. As is well known, arteriosclerosis is rare in early life, first appearing, on any considerable scale, between twenty-five and thirty-five, and increasing in frequency with advancing years. Aneurysm is associated rather with circumscribed than with diffuse and disseminated arterial disease. Aneurysm is more common in the colored than in the white race. It is rare in animals, even in those subjected to severe physical strain. Syphilis plays an important part in the etiology. From comparative observations with digestants and with stains, the conclusion was reached that the changes in the arteriosclerotic vessel are primarily molecular rather than histologic.

**Nurses' School Opened on Blackwell's Island.**—The new buildings of the New York City Training School for Nurses, on Blackwell's Island, were formally opened on Wednesday afternoon, December 2. Mayor Low should have made the introductory address, but was unable to attend. President Roosevelt sent a letter in which he regretted being unable

to be present at the opening services, and warmly commended the work. One building, named "Jones Hall," in honor of Mrs. Cadwalader Jones, to whom is due much of the credit of establishing the training school, is already completed. This building is a four-story structure, of which the first story contains a classroom, drawing room, and two rooms for the isolation of contagious cases of sickness, or the cure of nurses. The other stories contain rooms for the accommodation of nurses. The second building, in course of construction, has been named "Rice Hall," in honor of Mrs. William B. Rice. This building, when completed, will contain on the first floor the offices of the school, the chemical and bacteriological laboratories, and a room for the classes in dietetics. The other three stories will contain quarters for nurses. The central building, the present Nurses' Home, has been rechristened "Schuyler Hall" in honor of Miss Louisa Lee Schuyler, the founder of the State Charities Aid Association. Commissioner Folks presided at the dedication ceremonies, while Bishop Potter, Mrs. C. Jones, and Dr. Edward S. Peck gave addresses.

**Woman Dies of Glanders.**—A Mrs. Richard T. Mueller of Bridgeport, Conn., who had been married just a week, died recently of glanders, which she is said to have contracted from a horse belonging to her father. It is believed that she became infected through an abrasion on her right hand.

**A $250,000 Donation.**—The *London Times* stated in a recent issue that a gentleman, who wishes to remain anonymous, has given, through Professor Starling, £50,000 ($250,000) to University College, London, to be used for the promotion of higher scientific education and research.

**Fatal Football Injuries.**—Hugh Schofield, a school boy, twelve years of age, died on December 3, at Fishkill Landing, N. Y., from injuries received in a football game.

**State Board Urges Vaccination.**—The New York State Health Department has just issued its monthly bulletin. It draws attention to the possible increased prevalence of smallpox during the cold months, and dwells upon the necessity of vaccination. It recommends the enforcement of the law excluding unv accinated persons from the public schools.

**Anti-mosquito Convention.**—The first anti-mosquito convention to be held anywhere will meet in the rooms of the Board of Trade and Transportation, 203 Broadway, on Wednesday, December 16. Governor Franklin J. Murphy of New Jersey has been invited to preside. Addresses are expected, among others, from these: Dr. L. O. Howard, Washington; President Lederle of the Board of Health, John Clafflin, Street Cleaning Commissioner Woodbury, and Paul D. Cravath.

**The Health of the Kaiser.**—The reports received as to the health of the Kaiser are of so conflicting a character that but little reliance can be placed in them. One thing, however, is certain, and that is the marked apprehension of the German people in regard to their Emperor's condition. According to the New York *Sun*, December 6, those who have seen the Emperor since the operation on his vocal cords speak sympathetically of the sudden appearance of signs of age beyond his years, and his somewhat haggard expression. The fact is, that the Kaiser has overworked himself in every way, and in addition to his throat trouble is suffering from physical exhaustion. He needs a complete rest.

**A Kansas County's Curious Birth-Rate.**—More than two-thirds of the births reported to the Secretary of the Board of Health in Leavenworth County, Kan., have been boys.

**Harvard Medical School.**—The foundations are being laid for the new Medical School, and it is expected that by the fall of 1905 the school will be moved from its present quarters behind the Boston Public Library to the new buildings near the Fenway in Boston. The fund was started at commencement in 1902, when a gift of $2,000,000 from J. P. Morgan was announced. Subsequently donations were received from J. D. Rockefeller and Mrs. Collis P. Huntington, together with smaller contributions from friends of the university. Altogether a fund of $5,000,000 has been secured. There will be six large structures, five of which will be grouped about three sides of a court 520 feet long and 215 feet wide. The sixth building, to be used as a power house, will stand apart from the main group. It has been decided to give up at present the contemplated new building for the Dental School. The buildings alone will cost over $2,000,000, and it is believed they will be the finest of their kind in the world. They are to be constructed entirely of white Vermont marble, with the exception of their bases, which will be of pink Milford granite. The Medical School faculty are planning to have many affiliated hospitals near by. Among the several institutions to which the corporation has already made offers, and which have signified a desire to take advantage of the offer, are the Brigham Hospital, the Children's Hospital, the Samaritan Hospital, and the Infants' Hospital. The last mentioned, which is to be built in memory of Thomas Morgan Rotch, '01, will be smaller than was at first planned, as it has been decided to go ahead on the already existing gift of $76,000.—*New York Evening Post.*

**A New Laboratory for Harvard University.**—The Bussey Institution of Harvard University, situated in Jamaica Plain, is to have a new laboratory where vaccine and antitoxin will be manufactured for the State Board of Health, under the direction of Professor Theobald Smith of the Medical School. The estimated cost is $20,000, and it is expected the building will be ready for use by next April.

**Sickness at Annapolis.**—The exposure to which the midshipmen were subjected at the Army and Navy game in Philadelphia on November 28 is supposed to account for the large number of cases of tonsillitis recently reported. There are a large number on the sick list, some of whom are in the hospital, some confined to their rooms, while others are so slightly affected as to be able to keep at their work. Mumps, in epidemic form, also is present at the Academy, and about twenty cadets are ill with the affection.

**Mosquitos in New Jersey.**—According to the New *York Tribune*, December 6, Professor John B. Smith, New Jersey's State entomologist, in an address delivered before the New Jersey Sanitary Association's convention, declared that the complete extermination of the mosquito from New Jersey was possible. Dr. Charles Wardell Stiles also spoke at some length of the parasites which help to destroy the mosquito.

**Not to Unite with Brown University.**—President W. H. P. Faunce of Brown University writes: "My attention has been called to a statement in the MEDICAL RECORD of November 28 that a certain medical school in Boston is to unite with Brown University. Knowing how much you value accuracy in such matters, I ask you kindly to deny this groundless rumor. No officer of Brown University has ever dreamed of such a movement. Where the report originated I cannot imagine—certainly not at the University."

**Smallpox in Philadelphia** is at present more prevalent than it has been in many years, and the disease continues to spread, despite the most strenuous efforts of the health authorities. Unfortunately, many persons decline to be vaccinated, and thus become media for the extension of the epidemic. The most urgent need of the hour seems to be a statute making vaccination and revaccination universally obligatory. Ninety-nine new cases were reported for five days ending December 4, and 1579 more cases were reported since January 1, than during a corresponding period two years ago. The disease is not confined to any particular locality, but is pretty evenly distributed throughout the city. It is rather more prevalent in the congested sections, and negroes are the victims in large proportion. Foreigners, on the other hand, almost wholly escape, because they have been repeatedly vaccinated, both in their native land and on arrival in this country.

**The William Pearson Medical Association.**—The following have been reëlected officers of the William Pearson Medical Association of Essex County, N. J., for the ensuing year: *President*, Dr. Thomas W. Harvey of Orange; *First Vice-President*, Dr. Richard C. Newton of Montclair; *Second Vice-President*, Dr. Joseph C. Young of Newark; *Treasurer*, Dr. J. Hammond Bradshaw of Orange; *Secretary*, Dr. Richard D. Freeman of South Orange; *Librarian*, Henry A. Pulsford of South Orange; *Council*,—The above and Drs. Theron Y. Sutphen of Newark, William B. Graves of East Orange, and Mefford Runyon of South Orange.

**Gift to the Stamford, Conn., Hospital.**—It was announced recently at the commencement exercises of the hospital training school for nurses that Robert M. Bruce of Greenwich had given $10,000 to the Stamford Hospital. This is the first public announcement of the gift which was made over a year ago, but Mr. Bruce requested that no public announcement be made at the time. Mr. Bruce has recently founded an isolation hospital in Greenwich.

**The International Electrical Congress in 1904.**—Dr. William J. Morton of this city, in accordance with a resolution of the committee of Organization of the International Electrical Congress of 1904 at St. Louis, has been appointed chairman of the Section on Electrotherapeutics. This section is one of seven into which the work of the Electrical Congress has been divided. Mr. William J. Jenks, electrical engineer, has been appointed secretary of the same section. Dr. Morton also has been appointed one of the Committee of Organization of the Congress, a committee consisting of twenty-five members whose president is Prof. Elihu Thomson. It is the desire of the committee and of the chairman and secretary to secure foreign, as well as home, contributions of papers representing the present status of Electrotherapeutics; while certain authors will be invited to participate, voluntary contributions are also desired.

**Disinfection of Slate Pencils.**—The School Board of Springfield, Ohio, at the suggestion of Dr. Seys, the Health Officer, has decided to disinfect the slate pencils used by the children in the public schools. The custom has been to gather up in the evening all slate pencils used during the day, have them sharpened, and distributed again in the morning. Hereafter, if Dr. Seys' suggestion is acted upon, the slate pencils will be kept in formalin over night, then washed off and sharpened in the morning before being given out for use by the pupils during the day.

(From Our Special Correspondent.)

THE GREAT VIVISECTION LIBEL TRIAL—REPORT OF THE L. G. B. HOSPITALS; THE BANTS' SCHEME, HOME HOSPITAL, WATERLOO AND ITALIAN HOSPITALS—SHOPPING DAY—DEATHS OF DR. RUSSELL AND SIR R. M. CRAVEN.

LONDON, November 20, 1903.

THE vivisection libel case has terminated in the complete vindication of the assailed professor. You will not have forgotten that it arose from an attack by Mr. Stephen Coleridge at a meeting of the Antivivisection Society, when he read out a deliberately worded charge of torturing a dog by Dr. Bayliss, at University College. In his statement the alleged fact was dressed up with much clap-trap about the "never-ending procession of helpless dumb creatures" toward the college, the disturbance of students by the "whining and howling," "shrieks of agony," and so forth. But leaving the garnishing, the one definite charge of illegal torture of a dog on a certain date by certain operations he declared he was ready to establish by eye-witnesses of the cruelty. The challenge was taken up by Dr. Bayliss, who sued Mr. Coleridge in the High Court for his slander and libel. The trial extended over three days, before the Lord Chief Justice and a special jury, and ended on Wednesday in a verdict for Dr. Bayliss with £2000 damages and costs.

The trial lets a little light on some of the sinister proceedings of the antivivisectionists, and can scarcely fail to convince the public of the unreliability of their statements. The two witnesses promised were produced at the trial, and proved to be two Swedish ladies who were secretaries of an antivivisection society in their own country, who came here, according to counsel's statement, "with a view of studying fully and clearly seeing the working of the system among the most humane people in the world."

In their evidence it came out that they had written a book entitled "The Shambles of Science," which they began to write on April the first —a confession which elicited laughter in court; also "it was a very small book," on which the judge said "I am glad to hear it." In this book, the chapter describing the incident which led to the trial is headed "Fun." Miss Hageby, one of the Swedish writers, told counsel she thought that quite fair, and that in her book she had said the noises of the dogs seemed to have "an exhilarating effect on those present." Further, she never called attention to the state of the animal or complained that it was not under anæsthesia, although she intended to publish such a statement. She was there, she said, to see what was going on, to study the system, not one particular animal, and did not remonstrate, although, in her view, it was being tortured. The evidence of these boasted witnesses as to anæsthetics dwindled down under examination to the admission that they did not see the administration, just as the statement that it had not been tracheotomized turned out to be an absolute misstatement; that they did not see the tube which was proved by several witnesses to be in the throat all the time. But the breakdown of the ladies was less remarkable than the shuffling of Mr. Coleridge himself in the box. Asked if it would not have been fair to inquire if Dr. Bayliss denied the charge, he said he did not think what the ladies told him was unlikely; if he had asked he would not have had a civil answer, and he did not think he should have believed Dr. Bayliss if he denied what the ladies reported. In reply to the judge he said, "I believed the ladies and I believe them now." This, of course, was after the denials on oath of Professor Starling, Sir V. Horsley, Dr. Bayliss and several others.

The Lord Chief Justice, in the course of a luminous summing up, instructed the jury to dismiss from their minds any prejudice they might have on either side, to exclude all the extraneous questions that had been raised. They had not to consider whether the existing law should be changed or whether such operations should be permitted, nor yet the methods of controversy which had been referred to. He read some extracts from the "hysterical book" of the ladies, and said that if the statement they had made was true it was astonishing that they did not communicate it to anyone for two months. The defendant asked them to believe these ladies saw what they said they saw, and he had made no investigation further. It was for the jury to say whether the allegations made were true in substance and fact. If so, they would give the verdict to defendant; if not, they would give the plaintiff such damages as they thought proper, for no one had a right to import into public discussion slanderous defamation of another man unless prepared to prove his charges in a court of justice.

The annual report of the Local Government Board has

just been issued for the year ending March 31. It is a heavy Blue Book of over 1000 pages, and divided into five departments of local government and taxation, one of which is public health and administration. A great mass of details is dealt with, and many interesting points may be culled by anyone who has the time and courage to attack the bulky volume. Food adulteration, water supply, vaccination, infectious diseases, pauperism, medical relief and other matters of public health receive consideration; besides which, so many other subjects are handled that one can hardly wonder that the volume takes so many months to prepare.

An increase of pauperism, noted last year as having occurred in 1901 in comparison with 1900, appears to have continued in 1902. This rise commenced in the first six months of 1901. The number receiving relief on January 1, 1903, namely 847,480, was higher than on the same date in any year since 1873, when the number was 890,372. But compared with earlier years there is a decrease, and this is more apparent when considered in relation to the population. The ratio on January 1 last was 25.7 per 1000, while from 1863 to 1883 it ranged from 30.1 to 56.1 per 1000.

The statistics of vaccination seem to show 68.7 per cent. of the births as successfully vaccinated, while 11.2 died unvaccinated, 0.2 were insusceptible, and 4.3 were exempted on "conscientious objections."

A table gives details of infectious diseases notified in 1902, showing the percentage of deaths to cases notified was, for smallpox and diphtheria, 14.8; scarlet fever, 3.7; typhus, 22.4, and typhoid, 16.6. Notifications incur some expense, but not nearly so much as vaccination, against the cost of which some papers are protesting; they seem to think that doctors should work for nothing.

As to our water supply, Dr. Thorpe, the Board's analyst, examined 1223 samples; but there does not appear any striking variation in the quality. Adulteration of food still seems rampant. Penalties were imposed in 2928 cases, amounting in the aggregate to over £7000. Preservatives added comprised boric and salicylic acids and even formic aldehyde. The establishment of a standard for milk has led to the general reduction of good milk to that standard, just as was anticipated it would do; for of course the standard had to be so low as not to exclude poor, but genuine milk.

On Tuesday the deputation of the Governors of St. Bartholomew's Hospital waited on the Lord Mayor. The treasurer, Sir Trevor Lawrence, recapitulated the proceedings already taken, and pleaded with no little skill the claims of the hospital to assistance in obtaining £300,000 required to carry out the scheme which has been adopted. The Lord Mayor said he should have much satisfaction in identifying himself with the appeal, and granted the use of the Mansion House for a meeting to promote the cause. It was arranged that such meeting should be held on January 26.

The opposition to the scheme which the Governors have adopted has, however, by no means ceased. Indeed, in some quarters it has increased. One Governor has announced in the newspapers that he is organizing a definite opposition to the plan, which he thinks a step toward the ruin of the hospital, and for which he would substitute a much more radical one, to cost twice as much.

Sir H. Burdett, who looks upon himself as an authority on all hospital matters, is also in the field as an opponent of what he calls the "patchwork scheme," which he declares must mean that the hospital will ultimately fall into the second rank, if it does not lose its present usefulness in the metropolis and the empire. He therefore rejoices that opposition to the scheme is every day growing in volume and influence.

The Home Hospital Association is appealing for funds for rebuilding and refurnishing its pay-hospital. This is the only hospital for well-to-do patients, and is still in want of some £7000, although the terms of admission are such that it ought to be at least self-supporting. The managers say it will be after the above sum has been obtained.

The Royal Waterloo Hospital, for children and women, proposes to establish a military ward with the aid of the various London corps, the name and crest of a regiment to be fixed to each cot. The ward will be devoted to the children and wives of the rank and file. One donation of a thousand guineas, to endow a cot, has been offered on condition that five other similar sums are contributed.

King Edward Hospital Fund has already received above £1000 as the result of the Hospital Shopping-day. The committee anticipate further remittances from the firms which observed the day.

The Italian Hospital is taking the occasion of the visit of the King and Queen of Italy to plead for contributions, of which it is in sore need, as a mode of expressing our good will to Italy. The hospital admits patients of all nations, and I hear that about half of those received are British subjects.

Dr. Charles H. Russell, M.O.H., of Great Yarmouth, has fallen a victim to the risks of professional duty. During the visit of the Channel fleet, in October, he was called to one of the ships where typhoid fever had broken out, and superintended the removal of two cases to the isolation hospital, of which he was also the medical officer. He then became ill, and has not been able to leave his home since. A scratch on the foot from a hot-water bottle was followed by septicæmia, and he died on Wednesday.

He took the double qualification in 1874, the Public Health diploma of the R.C.P. in 1897. He served for a time as assistant M.O.H. at Southampton and as Port Medical Officer.

Sir Robert Martin Craven, F.R.C.S., J.P., consulting surgeon to the Royal Infirmary of Hull, died in that town in his eightieth year. He took his M.R.C.S in 1846, the L.S.A. in 1847, and began practice in 1848 in Hull, where he has resided ever since. He lectured on anatomy and physiology at the Hull Medical School for some years, and became a Fellow of both the Edinburgh and London Colleges of Surgeons. He was a magistrate for the East Riding of Yorkshire as well as for Hull, to which he had served the office of Sheriff. He was knighted in 1896.

## OUR PARIS LETTER.

(From Our Special Correspondent.)

MARMOREK'S NEW ANTITUBERCULOSIS SERUM—CONGRESS OF SCHOOL HYGIENE—CAFFEINE BEFORE VENESECTION—THE NEW FRENCH MILITARY LAW AND MEDICAL STUDENTS—SUPPRESSION OF SALT IN CIRRHOSIS AND HEART TROUBLE—DEATH OF DR. BRUN—FREQUENCY OF APPENDICITIS IN FRENCH ARMY—PREVENTION OF TUBERCULOSIS AMONG CHILDREN.

PARIS, November, 1903.

DURING the last week the subject which has attracted the most attention is the new antituberculosis serum of Marmorek, who made a communication to the Academy of Medicine, on this subject on the 17th of November. Dr. Marmorek was to have made his report a week before, but time was not found for it. It should be noted that Dr. Marmorek no longer belongs to the Pasteur Institute. Drs. Roux and Metchnikoff were opposed to his publishing his results so soon, before severe control over his experiments had been carried out, and Dr. Marmorek sent in his resignation. Dr. Roux wrote a letter to the *Temps* in which he indicated the reasons why the Pasteur Institute had felt it best that Dr. Marmorek should publish his results on his own responsibility.

There was a large gathering at the Academy of Medicine, numerous photographers being noticed among the audience. At the beginning of his report, Dr. Marmorek stated his reasons for sending in his resignation as chief of laboratory at the Pasteur Institute. He then described the method used to obtain his antitoxin. Young "primitive" bacilli are cultivated in a medium composed of leucotoxic serum of calf and bouillon of liver with glycerin. After having been cultivated a certain number of times in this medium, which is destined to resemble that furnished by the human body, there is no longer found any tuberculin, but on the other hand there is another toxic substance which kills small animals, and to which tuberculous animals do not react any more than those that are sound. These cultures are filtrated, injected into horses, and the serum obtained thus, is employed. This serum injected in doses of fifteen or twenty c.c., three days before the intravenous inoculation, prevents tuberculous infection in rabbits. To obtain a cure, however, larger doses are necessary. These experiments have been carried out for more than a year on human subjects. From the beginning Dr. Marmorek found his serum had no deleterious effect. Its curative effect varies very much. In meningitis the result was nil. For tuberculosis of the lungs, there was no effect in most cases. In some, however, there was a distinct amelioration. In pleurisy the result was quite noticeable in six cases out of seven. The effusion diminished rapidly, there being at the same time abundant enuresis. Professor Dieulafoy, who had tried the serum in his clinic at the Hotel Dieu, reported poor results. Dr. Hallopeau, declared after the meeting was over that in the treatment of lupus at St. Louis he had obtained no result. Dr. Lucas-Championiere had tried it on five patients suffering from bony tuberculosis, without other results than those seen when serum is injected. Lastly, experiments carried out on guinea-pigs had given unsatisfactory results. The medical editor of the *Matin* has written an editorial on the serum of Marmorek in which he does not seem to be very partial to

him, Koch's fiasco, fifteen years ago, being brought up as a warning.

On the 1st of November a congress was held in Paris in which the question of school hygiene was discussed. This meeting was brought about by the efforts of the league of physicians and families in the interests of school hygiene, Dr. Legendre, who is deeply interested in all such questions, described the qualifications that the school physician should possess. (It should be noted here that every large school in France has a physician attached to it.) The general construction of the building should not be undertaken until he has been consulted. Special rooms for contagious diseases ought to be set aside. All such diseases as parasitic diseases, adenoids, eye or ear troubles, scoliosis, dental decay, neuroses, must be looked for by the physician. A great number of cases of lack of intellectual development are due to ill health. The hours of study and recreation should also be inquired into. In a recent number of the *Presse Médicale*, Dr. Legendre recommends the use of caffeine in some cases of venesection. When this treatment is carried out, it may happen that the contractions of the heart are already weak, and that therefore not much blood can be drawn. In such cases, the caffeine injected will strengthen the heart, and one will be able to draw off much more blood.

The new French military law, which requires two years of military service irrespective of the profession, will be specially hard for medical students, who have so far only been obliged to pass one year in the army. It would, however, be better if in France they did as in Germany, where the students are called at the end of their studies. In this manner the army is furnished with a sufficient number of medical men. At present the medical students serve in the hospitals as aids, or orderlies, and in case of war they would be unable to fill their new rôle in a satisfactory manner.

The new treatment of œdema in acute nephritis, by the suppression of salt, has been applied by Dr. Achard to the treatment of ascites caused by cirrhosis or heart trouble. In one case of a woman, suffering from alcholic cirrhosis, the milk regimen had not been able to check the ascites. After eight days of milk the weight was stationary. A regimen containing very little salt and fairly abundant in sugar and amylaceous food was then tried, and the weight decreased immediately. In twenty-five days the loss was twenty pounds. No drugs were given in this case. In another case the weight increased steadily, and only remained stationary when this peculiar diet was given. The patient in this case was suffering from heart disease, enlarged liver and ascites.

Dr. Brun, surgeon of the Enfants Malades Hospital, has just died. He was considered a very reliable surgeon, and had worked extremely hard to obtain the position which he occupied. He was one of the candidates for the professorship of infantile surgery which, however, was given to Kinnisson.

At a recent meeting of the Académie de Médecine, Dr. Chauvel, an army medical inspector, described the statistics obtained on the frequency of appendicitis, in the French army. In 1901 there were 461 cases of appendicitis, or about one in every thousand. In 1902 there were 619, or 1.27 per thousand. A strange fact is, that in Algeria and Tunisia, the number of cases is half as small, there being only 0.44 and 0.67 per thousand. Dr. Chauvel has examined this question still further, and has found that, whereas this disease was relatively frequent among European soldiers, it was much less so among the native troops, there being only thirteen cases of appendicitis in four years among a body of 17,000 soldiers. This might be due to the fact that the Arabs are very abstemious, only eating a small amount of very well cooked meat. The same holds true in Persia, where Dr. Schneider, physician of the Shah of Persia, has only seen five cases of appendicitis in ten years. At Teheran, no pork or beef are eaten, and chicken and mutton are very well cooked. Matignon, who was for five years physician at the French embassy at Pekin, never saw a single case of appendicitis at the French missions, nor at the Nan-Tang Hospital. In Brittany very few cases of appendicitis are seen, and in that part of France the peasants do not eat much meat.

Professor Granscher does not consider that sanatoria are the most important means of stamping out tuberculosis. Prevention is much better, and he advocates using all methods which tend to protect children from this disease. He upholds the English method, which consists in ameliorating the hygienic conditions of workmen, in furnishing more light and air, and better food. Under the direction and inspiration of Professor Grancher, a society has been formed which aims to protect children from tuberculosis. The children of poor parents, who are affected with consumption, will be sent into the country, after having been examined, to note if there is any apparent trace of consumption. It is considered best not to send tuberculous children among families residing in the country, who would not know how to protect themselves. The family of the child will be asked to contribute, in some slight degree, to the maintenance of the child. The sum may be only two or five francs a month, but it will prevent pauperizing the family. Only children from five to thirteen years old will be chosen.

## Progress of Medical Science.

*The Boston Medical and Surgical Journal, December 3, 1903.*

**Hypernephroma.**—Paul Thorndike and John H. Cunningham, Jr., present the following summary of their paper: An affected kidney may not be much increased in size, but is generally very large. The general outline of the organ is usually retained, and the surface is almost always nodular, although occasionally there is no external evidence of the growth. The new growth is either encapsulated within the kidney substance or just below the kidney capsule. On section the tumor tissue is generally yellowish, with a firm and distinct stroma, which gives the growth a nodular appearance. Some of these nodules usually show areas of hemorrhage and degeneration. The kidney tissue is either destroyed or pressed upon and distorted by the new growth.

**Intestinal Parasites in Appendicitis.**—J. C. Hubbard concludes that: An intestinal parasite causes appendicitis through its presence as a foreign body; and by its struggles may bring about a perforation and peritonitis where otherwise none would have occurred. Trichocephalus dispar has been proved to cause an inflammation of the appendix by injuring the mucous membrane while sucking the blood of the host. Ascaris lumbricoides has been found with a material similar to that in trichocephalus in its intestinal epithelium, and therefore is supposed to attach itself to the mucosa of the host and thus start the processes which result in appendicitis. No proof has been found that oxyuris vermicularis causes appendicitis except in its rôle of foreign body.

**A Case of Sarcoma of the Lower Jaw.**—F. B. Lund reports this case: The patient was a girl of thirteen years, suffering from sarcoma of the lower jaw. This tumor originated in the medulla. It resulted in a fusiform swelling of the lower jaw. At operation an external incision was made along the body and angle of the jaw, the facial artery divided, and the periosteum peeled from the entire body of the jaw. The jaw was divided by a saw and cutting forceps just anterior to the socket of the canine tooth in front and at a point on the ramus of the jaw level with the alveolar process behind; all suspicious tissue was removed, including the submaxillary gland. The patient made an excellent recovery. The periosteum has evidently replaced the lost bone to a considerable extent, as a firm, bony bar can be felt in the place of the bone which was removed.

*Journal of the American Medical Association, Dec. 5, 1903.*

**The Legitimate Therapeutic Uses of Alcohol.**—In a discussion of this subject, O. T. Osborne states his belief that alcohol as a nutriment is uneconomical to the system, and if long used is a positive disadvantage, probably even sugar being better when the amount of food obtainable is too small for the needs of the body. During feverish processes, however, as a nutriment to furnish material for the production of heat to save the tissues, fat, and muscles, it is of decided advantage and probably has no equal, if in such fevers not enough nutrition is taken. Undoubtedly at the present time many cases of fever are overfed. Whether whiskey or brandy should be given in every case of typhoid fever or diphtheria, or in the feverish debility of tuberculosis, or in other acute infections, is a question that each practitioner must decide for each individual case. Many such cases do well without it; many cases recover only by the use of it.

**Vaginal Exploratory Puncture and Cœliotomy.**—C. O. Thienhaus extols the advisability of these procedures in doubtful diagnosis in diseases of the pelvic organs, and says that there is no longer any question that vaginal incision and drainage in cases of abscesses of the pouch of Douglas, whether they originate from an infectious process in the uterus following abortion or birth or from a pyosalpinx or an appendicits, is the method *par excellence*. Nobody questions, furthermore, the advisability of the vaginal route for retro-uterine hæmatocele when infected either by way of the uterus or by way of adherent bowels. So long as we do not know whether or not the pus in an abdominal abscess is *pus bonun et laudabile*, so long as we are not in the possession of measures to determine the virulence of the bacteria and of the toxins present in the pus focus before operation, so long it must be our duty to open abdominal abscesses—when there exists a pos-

sibility—by an extraperitoneal route—that is, in women the Douglas abscesses by posterior vaginal cœliotomy.

**Carcinoma and Tuberculosis Treated by the Röntgen Rays.**—G. E. Pfahler reports several cases and presents photographs. His conclusions as to the efficacy of the treatment are expressed as follows: (1) The *x*-rays are of undoubted value in the treatment of certain cases of both superficial and deep-seated carcinoma and tuberculosis. (2) The more a case has been tampered with, the less likely it is to yield to the influence of the *x*-rays. (3) Daily treatments, carefully and properly given, will produce the best results. (4) We should try never to produce a dermatitis beyond a simple erythema. (5) There are idiosyncrasies in certain people which render them most susceptible to the *x*-rays, and in these people deeper burns may occur in spite of the most careful treatment. (6) Epithelioma, involving the mucous membrane, is much less likely to yield to the effect of the *x*-rays than when it simply involves the skin. (7) There is not likely to be any interference with the sense of sight, even though the *x*-rays are used directly over the eye. (8) Tuberculosis, whether of the skin or of the glands, will yield at least in certain cases to the effects of the *x*-rays. (9) The *x*-rays may be of value in certain cases of deafness. (10) The *x*-rays will give better cosmetic results than any other form of treatment in simple epithelioma of the face. (11) Epithelioma of the mucous membrane should be removed as early as possible by the knife, and this followed by *x*-ray treatment. (12) Operable cases should be operated on and in each instance followed by a course of *x*-ray treatment, and *x*-ray treatment should be given at the first sign of a recurrence. (13) Inoperable cases should be given a trial with the *x*-rays, since even hopeless cases sometimes yield to this form of treatment. (14) It is desirable to produce a distinct reaction in the treatment of lupus.

*Medical News, December* 5, 1903.

**The Degree to Which Substances Agglutinating the Dysentery Bacilli Are Present in the Blood of Non-infected Persons.**—Lawrence B. Pilsbury concludes: That the serum of non-dysenteric adult patients does agglutinate the shiga and acid type (Flexner) bacilli frequently in a 1 to 20 dilution and occasionally in a dilution as high as 1 to 100. That this agglutinating power is wanting in the blood of non-dysenteric young infants (under one year), rarely being present even in a 1 to 10 dilution. That there are certain differences in agglutinating capability between the Shiga and acid type (Flexner) bacilli, the former in these tests clumping somewhat more readily than the latter. That a decided and prompt reaction, under two hours, with the bacillus dysenteriæ in dilutions of 1 to 20 or higher in young subjects (under one year) and in 1 to 50 or higher in older persons who have not recently suffered from chronic or subacute intestinal disease, is probably pathognomonic of acute epidemic dysentery.

**Report upon the Results with Different Kinds of Pure and Impure Milk in Infant Feeding in Tenement-houses and Institutions of New York City: A Clinical and Bacteriological Study.**—Wm. H. Park and L. Emmett Holt present a summary of their paper. The observations were made upon infants for periods of about three months only, and the conclusions relate especially to the more immediate effects of the milk. (1) During cool weather neither the mortality nor the health of the infants observed in the investigation, was appreciably affected by the kind of milk or by the number of bacteria which it contained. The different grades of milk varied much less in the amount of bacterial contamination in winter than in summer, the store milk averaging only about 750,000 bacteria per c.c. (2) During hot weather, when the resistance of the children was lowered, the kind of milk taken influenced both the amount of illness and the mortality; those who took condensed milk and cheap store milk did the worst, and those who received breast milk, pure bottled milk, and modified milk, did the best. The effect of bacterial contamination was very marked when the milk was taken without previous heating; but, unless the contamination was very excessive, only slight when heating was employed shortly before feeding. (3) The number of bacteria which may accumulate before milk becomes noticeably harmful to the average infant in summer, differs with the nature of the bacteria present, the age of the milk, and the temperature at which it has been kept. When milk is taken raw, the fewer the bacteria present the better are the results. (4) When milk of average quality was fed sterilized and raw, those infants who received milk previously heated, did, on the average, much better in warm weather than those who received it raw. (5) No especial varieties of bacteria were found in unheated milk which seemed to have any special importance in relation to the summer diarrhœas of children. The number of varieties was very great, and the kinds of bacteria differed according to the locality from which the milk came. (6) After the first twelve months of life, infants are less and less affected by the bacteria in milk derived from healthy cattle. When the milk had been kept cool the bacteria did not appear to injure the children over three years of age, at any season of the year, unless in very great excess. (7) The use, for infants, of milk delivered in sealed bottles, should be encouraged whenever this is possible, and its advantages duly explained. Only the purest milk should be taken raw, especially in summer. (8) Since what is needed most is intelligent care, all possible means should be employed to educate mothers and those caring for infants in proper methods of doing this. (9) Bad surroundings, though contributing to bad results in feeding are not the chief factor. It is not, therefore, merely by better housing of the poor in large cities that we will see a great reduction in infant mortality. (10) Close percentage modification of milk, although desirable in difficult cases, is not necessary to obtain excellent results with the great majority of infants, and a certain adjustment of a healthy infant to its food is usually soon secured. (11) The injurious effects of table food to infants under a year old, and of fruits to all infants and young children in cities, in hot weather, should be much more generally appreciated.

*New York Medical Journal, December* 5, 1903.

**Twists in Normal and in Congenitally Dislocated Femora.**—R. Soutter and E. H. Bradford give the rules they have followed in determining femoral twists, illustrating their statements by a series of diagrams which must be consulted by those interested. One hundred and fifty-four measurements have been made and are recorded in tabular form. Concerning the practical bearing of the twist on manipulations for reducing dislocations, the authors note that where much twist exists, the manipulation is different from what is needed where the amount of twist is small. There is also a greater danger of transposition, *i.e.* a forward dislocation, as the ultimate result following reduction, if an amount of twist in the femur exists to a degree beyond the limit compatible with normal function. The degree of rotation in a case of congenital hip can be estimated by palpation in children with hips not well padded with fat or muscle, but where the head of the femur cannot be well felt no estimate of the amount of twist can be made except by *x*-ray pictures.

**Carcinoma of the Breast Treated by Massive Mercuric Cataphoresis.**—The patient of G. Betton Massey was a woman of fifty-seven years with breast involvement dating back seven months. The mass in the outer half of the right breast measured about two inches and a half in diameter, and was movable on the chest wall. The skin overlying the growth had been invaded by the cancerous process, and presented an area of ulceration about the size of a dollar. In the axilla there was a movable enlarged gland, the size of a peach stone, showing that the disease had advanced to the stage of regional infection. Electrodes of zinc, coated with mercury, were inserted one at a time into the growth near its periphery, and the current turned on. From time to time one of the points was removed, when sufficient necrosis had appeared at its situation, was recoated with mercury and inserted in a new place. In this way a large mass was removed by marginal sloughing and came away in six weeks, leaving a granulating wound. Four months later the patient was doing well in every way.

*American Medicine, December* 5, 1903.

**Mycotic Disease of the Ear Canal; with Report of a New Fungus.**—S. E. Cook reports the case of a patient suffering from an obstinate parasitic otitis. Examination of material removed from the ear showed the specimen to be sterigmatocystis candida, of Saccardo, a species hitherto unknown, or unreported as existing, in the human ear canal. Parasitic otitis may be noted at any season of the year and in almost any locality. Purulent disease of the middle ear is very rarely associated with fungous otitis, unless there be coincident inflammation of the ear canal. The prognosis is good in relation to the destruction of the fungus. Under proper treatment most patients recover promptly.

**A Logical Definition of Typhoid Fever.**—Henry A. Fairbairn gives the following definition: Typhoid fever belongs to the genus disease, to the species acute infection having the property of toxæmia and as accidents focal lesions. The essential characteristic is that it has as the associate with its lesions and as a determinate cause the Eberth-Gaffiky bacillus. While it presents, pathologically and clinically, a fairly constant picture when the bacillus is localized and develops in the lymphatic structure of intestine and mesentery, yet all this may be changed by its development in other quarters. Animals have repeatedly

exhibited the essential characteristics of the disease. The writer insists on the more frequent employment of chemic and bacteriologic tests for the presence of the bacillus.

**Treatment in 442 Cases of Movable Kidney without Surgical Intervention.**—Charles D. Aaron declares that it is not an easy matter to fit a band to patients having ptosis of the abdominal viscera. Every case is one unto itself, and demands the most careful study and consideration. The writer maps out in each case the position of the kidney, liver, spleen, and stomach, besides inflating the colon with air in order to be sure that there is not a coloptosis. When a band is fitted, care must be taken to so arrange the pads that all of the displaced organs may be held up, and that at the same time, equal pressure may be exercised over the entire abdomen. The writer does not think that operations for movable kidney have given good results. He believes that the wearing of properly fitted bands gives the best results. After a band that immobilizes the kidney, and supports the other displaced organs has been applied, the beneficial effects are felt immediately. The patients feel relieved, are much stronger, and are able to breathe better. Those who have had distress after meals, are able to eat without discomfort. Weakness, constipation, insomnia, and distress begin to subside. On the whole, improvement is very rapid. The band is necessary only until all these symptoms subside. The writer's custom is to have his patients wear the band a year. Besides the benefit which comes from a properly fitted band, diet, tonics, electricity, and massage all hasten the result of the treatment.

*The Lancet, November* 28, 1903.

**Patent Medicines.**—In a lecture, by R. Hutchinson, on patent medicines, in which he gives the results of analysis of many of the nostrums before the public, he says that the medical profession must counteract the prevalent tendency of the laity to use such remedies by doing two things: First, we must educate the public in the elements of physiology, so that they will realize that the same set of symptoms may be produced by many totally different diseases, and will distrust anyone who claims to have a panacea which will immediately effect a cure, no matter what may be the cause. Second, it ought never to be possible for a patent medicine-seller to truly say that he has cured a patient after a physician had failed so to do, and this means that we must give more attention to the treatment of disease, and especially of minor ailments than we do at the present time.

**Albuminuria as an Accompaniment of Diabetes Mellitis.**—In the opening portion of a lecture on this topic, F. W. Pavy cites the notable frequency of the association of these two affections. From this association he argues that it may be assumed that some condition or other connected with diabetes tends to affect the kidney, and to lead to the production of albuminuria, but the latter may also be developed in the diabetic patient, from the causes that lead to its development in the non-diabetic, and thus constitute a purely independent affection. Hence, we may have albuminuria as either concurrent with, or consecutive to, the diabetes. As a rule, the distinction can be drawn between the two from the features observable in connection with the case. In the former of the two instances the albuminuria presents itself as a concomitant of Bright's disease which may happen to become independently developed during the existence of a diabetic state. When such an event occurs, a different train of phenomena is met with from that following the advent of albuminuria as a consecutive condition upon diabetes. Springing from an outside source, the albuminuria is associated with the classical phenomena of Bright's disease. The case virtually falls in the category of Bright's disease, and apart from the condition of the urine is easily recognizable as such by the characteristic symptoms presented. With Bright's disease developing in this way, the diabetes may be found to decrease and even to disappear.

**Fracture of the Fifth Cervical Vertebra; Recovery.**—The patient of W. E. F. Tinley and A. R. Jones was a man who had fallen a distance of forty feet on to a slope, and had rolled down the latter for some distance. Some hours later he presented the following condition: Semi-consciousness with almost complete loss of power in the legs, some loss of power in the arms, complaint of pain in the back of the neck, contracted pupils, no hemorrhages. The next morning he had recovered consciousness. Catheterization was necessary. There was complete paralysis of the lower limbs and absence of patellar, epigastric, cremasteric, and other superficial reflexes. Bed-sores soon began to develop. Examination of the cervical spine located a tender spot over the fifth cervical vertebra. He remained in this condition for several months, and then, about seven months after the injury, began to improve. One year after the injury he was discharged from the hospital. He then walked with a distinctly spastic gait. He had good movement at the ankles, the knees, and the hips, and greatly increased knee-jerks; the superficial reflexes were normal; the intercostal muscles still lacked power. He had control over his urine, but occasional want of control over his motions. He was able to flex and to extend his fingers to some extent, but some of the joints were quite ankylosed. The left shoulder and the elbow were capable of movement to almost the normal extent, but his right elbow was nearly fixed at a right angle. He could feed himself and hold a paper to read. The nutrition of the body was fair; that of the skin was good. Over the fifth cervical vertebra was a distinct boss of bone as large as a walnut, and he carried his head bent forward and stiff.

*British Medical Journal, November* 28, 1903.

**Diabetes Mellitus with Rapidly Fatal Termination Following Typhoid Fever.**—J. F. C. Meyler reports this case. The patient was a man aged twenty-four years. He passed through a severe attack of typhoid fever with recrudescences. During the course of the fever jaundice developed, but passed off. Sugar was absent from the urine during the entire time that the patient was in the hospital. About a week after his return home he began to complain of intense thirst. He was passing large quantities of urine and was suffering from great weakness. He grew gradually worse, and finally died in coma. The course of the diabetes was very rapid—thirty-five days. There was no family history to suggest diabetes.

**The Etiology of One of the Heterogeneous Fevers of India.**—C. Donovan has found, in the blood from the spleen of a native boy, bodies belonging to the genus Piroplasma. He has found these parasites in sixteen cases among patients in his hospital. These have all been from punctures of the spleen and liver during life. The symptoms of this fever are enlarged spleen and liver, irregular pyrexia, paroxysmal œdema of the feet, congestion of the lungs, occasional subcutaneous hemorrhages, and cancrum oris. The medication—quinine, arsenic, and sodium salicylate—has proved ineffectual. The writer has found Piroplasma in the blood of two calves.

**Case of External Urethrotomy Treated by Continuous Retention of a Rubber Catheter Held in Position by a "Perineal Stop."**—C. Hamilton Whiteford sums up the advantages of a rubber catheter securely fixed. The patient is free from pain, and can turn freely in bed without risk of the catheter slipping out. The catheter can be retained continuously for several weeks, being removed every few days for cleansing—in fact, until the perineal wound is nearly closed. Retention of the catheter being continuous instead of intermittent, as is the case with a metal instrument, the wound heals round the catheter, and consequently the lumen of the strictured urethra is larger and requires less subsequent dilatation. Rigors are avoided, since the urine does not come in contact with the raw surface. The catheter, "stop," and clip, are easily sterilized by boiling. Tapes, plaster, rings, etc., are dispensed with.

**The Treatment of Vesical Papilloma by Injections.**—Herbert T. Herring believes that recurrence of papilloma after removal by suprapubic cystotomy, which unfortunately very frequently occurs, may be effectually held in check by injections of silver nitrate. If injections are made when it has been found impossible to remove the growth entirely by operation, the recurrence of the symptoms is retarded longer than could be expected without the treatment. Much of a tumor may be removed by the urethra without serious hemorrhage, and with a result gained equal in some cases to that of a suprapubic operation. There is reason to hope that papillomatous growths may be entirely destroyed by long-continued applications of silver nitrate. Injections should be made after operations for the removal of the growth, whether the operator is satisfied that he has done so efficiently or not. The urethral route should be tried, when removal of the papilloma is contemplated, before a more serious operation is undertaken.

*Deutsche medicinische Wochenschrift, November* 19, 1903.

**The Prophylaxis of Gastric Carcinoma.**—Alexander Katz cites various facts to prove that gastric carcinoma is, in part at least, the result of long-continued mechanical irritation of the gastric mucosa, due to the more or less solid nature of its contents. The stomach and the rectum—that is, the two parts of the alimentary tract whose contents are solid—are those most frequently the seat of malignant growths, while the small intestine which transmits only fluids is never attacked. The author therefore suggests as prophylactic measures extremely thorough mastication and the avoidance of uncooked foods in order

to have the stomach contents as free from undigestible matter as possible. A diet composed to a greater degree of semi-liquid constituents and the habit of drinking freely at meals are also to be encouraged.

**A Contribution to Mobility of the Heart.**— Silbergleit describes a case in which the entire heart was capable of a lateral displacement of several inches by a change from the left lateral to the right lateral position. The patient was a man of twenty-four years who came under observation for gastroenteritis, and was found in addition to be suffering from a moderate degree of chlorosis. He had no subjective symptoms referable to the heart, and in the standing position or when lying on the back, physical examination of the organ also was negative. When lying on the left side, however, the apex beat was three centimeters outside of the mammary line and the right border one centimeter to the left of the left sternal margin. When on the right side the apex beat appeared close to the left sternal margin and the right border was correspondingly displaced. Together with the cardiac displacements to the right or left, slight irregularity of action was observed. The author cites the case as a proof of Braun's statement that abnormal mobility of the heart does not of itself produce symptoms, and that when such are present their cause must be sought in organic disease.

**The Diagnosis of Gastric Ulcer Concealed by Hemorrhage Detected in the Fæces.**—Boas calls attention to the frequency with which a doubtful diagnosis of gastric or duodenal ulcer may be made positive by the demonstration of minimal quantities of blood in the gastric contents or fæces. Gastritis of the antacid, subacid or acid type, cases of hyperacidity, and of hypersecretion never give rise to concealed hemorrhage, according to the author's observations. The demonstration of blood in the gastric contents is liable to error owing to the probability of mucous abrasions occurring in the act of procuring the material, and before an analysis of the stools, hemorrhoids, colitis, etc., as possible sources of bleeding must be excluded, and underdone meat must not be eaten for two days previously. Even when ulceration is present blood is not constantly found in the stools, and repeated examination must be made before the result can be considered reliable. Even at best a negative result has less diagnostic value than a positive one, to which the same significanec attaches as to the gross hemorrhages constituting hæmatemesis or melæna. The author employs the following modification of Weber reaction: Five to ten grams of fæces are brought to a mushy consistency with water and the fat extracted with about twenty c.c. of ether. Three to five c.c. of glacial acetic acid are added to the residue and a second extraction made with ether. No alcohol must be added, as it gives rise to fallacies. Several grains of gum guaiac are added to the ether extract, and when dissolved twenty to thirty drops of resinified oil of turpentine are added. If blood is present a violet color gradually appears, which is increased by the addition of chloroform. A useful control is the use of a fresh solution of aloin in 60 to 70 per cent. alcohol in place of the guaiac. The aloin is to be added after the turpentine, and the presence of blood causes the prompt appearance of a light red color. Peroxide of hydrogen may be used advantageously in place of the oil of turpentine in both tests.

*Berliner klinische Wochenschrift, November* 6, 1903.

**Urticarial Œdema.**—Löwenheim describes a form of angioneurotic œdema, common in Silesia, and evidently of an infectious nature. The region where the disease is encountered is low-lying and swampy, and the persons attacked have usually been exposed to the night air. The prominent symptoms are chills, fever, œdema of the face, eyelids, nasal, and buccal mucous membranes, and a tendency to sciatica. Other parts of the body, as the hands and arms, sometimes show the œdema. No malarial organisms or other direct means of conveying the infection could be discovered.

**The Preventive Treatment of the Syphilitic Primary Lesion.**—Holländer reports his results in the treatment of syphilitic chancres by cauterization. This is done, not by the ordinary method, but by what the author terms cauterization without contact, accomplished by directing a stream of air at a temperature of 400°C. upon the affected part. Contact with the hot iron of the actual cautery produces local destruction of tissue unaccompanied by more diffuse action, as may be demonstrated by microscopical sections, while the author's method causes mummification of a wide zone, surrounding the region operated on and including both the superficial and deep parts. The procedure further offers a positive diagnostic test as to the nature of the ulcer; after such cauterization a syphilitic lesion presents a tough leathery surface from which no débris can be scraped with the sharp spoon, while indurated nonspecific ulcerations are soft and friable, and may be completely excavated by curetting. Fifty-nine cases in which the diagnosis of syphilis had been made with certainty were treated by this method, with the following results: Twelve suffered a general infection, in three the result was doubtful, while of the remainder twenty-two have remained free from all secondary symptoms for from one to two and a half years. In a number the completeness of the cure was corroborated by such facts as prompt marriage with non-infection of the wife, the birth of healthy children, a second syphilitic infection, etc. Even lesions of fairly long duration and with inguinal glandular enlargement were treated with happy results, the glands being in some instances extirpated. A point of importance is that even when secondary manifestations did appear after the cauterization, they were late in showing themselves, were few in number, and unusually mild in nature. The author, therefore, recommends the treatment for all forms of hard chancre, including extragenital lesions, as affording the best means of diagnosis and cure at our disposal.

*Münchener medicinische Wochenschrift, November* 17, 1903.

**Transitory Psychical Aberration Following Exposure to Cold.**—Vogt describes the case of a locomotive fireman who was forced to travel twelve miles against the wind on a reversed engine, so that he was unsheltered, on a night when the thermometer was 16° F. The effect of the cold was increased by the fact that he had lost his cap early in the trip. The next day he showed complete amnesia and soon lapsed into a semi-stupor, which persisted three days and then gradually subsided, leaving no traces. There was no hereditary or other taint, epilepsy is excluded, there were no physical signs of any nervous lesion during the attack, and there have been no symptoms since. The author, therefore, concludes that the condition was allied to that produced in cases of insulation, the exposure of the cranium in this instance making the brain the special seat of the thermal insult, as in sunstroke, the supposition being that extremes of heat and cold can produce analogous effects.

**Morphine Scopolamin Narcosis.**—Korff details the disadvantages inherent to the customary methods of anæsthetization which make an absolutely safe, uncomplicated, universally applicable system of narcosis an urgent desideratum. While he was an ardent advocate of the morphine scopolamin injections as first practised, and himself saw no bad results, still the experiences of others has shown that the plan is unsafe and must be abandoned. He has, therefore, modified it by markedly cutting down the amounts of the alkaloids until the doses are well within the limits of safety. Given in the prescribed manner, satisfactory anæsthesia is still obtained, though, in isolated cases, the inhalation of a few drops of ether or chloroform may be necessary during especially painful steps of the operation. Sixty cases are reported, all uncomplicated. One milligram of scopolamin hydrobromate and 25 mg. of morphine hydrochlorate are given subcutaneously in three portions: the first two and one-half hours, the second one and one-half hours, and the third one-half hour before the operation.

**Ether Narcosia Combined with Morphine and Scopolamin Injections.**—Hartoz says that ether is gaining ground rapidly in Germany a asroutine anæsthetic, and that its tendency to produce post-anæsthetic nausea and aspiration pneumonia is practically its only drawback. The latter complication is due to the inhalation either of the saliva, which is always secreted in large quantities, or of vomitus. Various attempts have been made to modify this tendency of the anæsthetic, and of these the most promising is the injection of scopolamin and morphine. As first used, this combination was intended to supplant other anæsthetics completely, and the alkaloids were given in doses sufficient to paralyze the faculties without the assistance of any other agent. The high mortality which speedily followed, however, proved the method too dangerous to be persisted in, but the author has found that, given in amounts too small to be hazardous, scopolamin and morphine react most favorably on ether anæsthesia, producing a narcosis agreeable to the patient and free from vomiting or salivation and their attending dangers. The routine is as follows: First the usual preparation, catharsis, fasting, etc.; then one-half to one hour before the operation the infection of one-half milligram of scopolamin in freshly prepared solution, and one centigram of morphine. The anæsthesia is begun one-half to one hour later with ether, on Wanscher's mask, administered very gradually, so that the surgical degree is not produced till ten minutes or more have elapsed. No danger need be apprehended from this dosage, and the patients are not salivated or nauseated and recover from the anæsthetic without the usual prostration. Ninety-three cases treated in this way gave excellent results, but on several subsequent occasions a protracted tachycardia was observed.

*French and Italian Journals.*

**Operative Interference in Infective Wounds of the Kidneys.**—Francesco Sorrentino reports a case in full, and concludes that a renal wound of a certain extent, if left to itself, almost invariably leads to infection of the renal region. The surgeon's duty is then to perform nephrectomy, no matter how grave the condition of the patient. After the operation the condition of the bladder must be carefully watched. If for several days it harbors blood-clots, it may easily become the seat of sepsis, and epicystotomy performed in time may save the patient.—*La Riforma Medica*, October 28, 1903.

**The Antistreptococcius Serum in Puerperal Infection and in Erysipelas.**—Pietro Guizzetti concludes from his experimentation that this serum is of benefit in puerperal septicemia. The fever falls, the pulse improves, there is absence of albuminuria, diminution in the size of the spleen, etc. It also prevents streptococcic infection. The effect on the uterus itself is beneficial, but slow. In erysipelas it brings about improved conditions after about twenty-four hours.—*La Riforma Medica*, November 11, 1903.

**The Subcutaneous Injection of Caffeine.**—H. Huchard and Ch. Fiessinger hold that practitioners have made a mistake in giving up the use of this remedy. It is of the greatest use in syncope and adynamic conditions, given in small doses of about four to eight grains. In infectious diseases it may give place to camphorated oil especially in nervous cases. In cardiac affections the doses may range from eight to twelve grains, but should not go above fifteen grains. As a rule, it is prescribed after digitalis has failed to give relief. In some rare cases it may be given first—*Journal des Praticiens*, October 31, 1903.

**The Tuberculous Serum Reaction.**—Guido Marchetti and Paolo Stefanelli conclude from their researches that in grave cases of tuberculosis, the serum reaction, applied according to the method of Arloing and Courmont is positive within the first six hours in 43 per cent. of the cases. In incipient or light cases, it gives positive results in 88 per cent, of the cases. In three cases of lupus the reaction was negative, as it was in nine cases out of ten in which the clinical symptoms did not indicate tuberculosis. After the first six hours the reaction occurs in cases which are not tuberculous, for which reason it can be used as a means of diagnosis only during the first six hours.—*Rivista Critica di Clinica Medica*, October 31, 1903.

**Appendicitis in the French Army During the Past Few Years.**—M. Chauvel states that the general impression among army surgeons in Algeria and Tunis, is that Mussulmans are rarely affected by appendicitis. Europeans living in warm climates also possess a relative immunity. As to the cause for this exemption M. Robert holds that it is because grippe is so rare in Algeria, while Schneider and Kelsch also appear to consider that influenza and appendicitis are in some way connected. The author believes, however, that the vegetarianism of the people, their sobriety, and their natve resistance to infections play the chief part, while a warm, dry climate certainly has some influence. The influence would seem to be that excessive meat eating predisposes to appendicitis.—*Le Bulletin Médical*, November 4, 1903.

**Iboga and Its Active Principle.**—Dibowski and Fandrin, Phisalix, Lambert and other scientists have studied the properties of this plant which comes from the Congo, and of its active principle, ibogaine. Medicinally, the latter is a powerful tonic, small doses of which can be given without danger, and will be found useful in cases of muscular or nervous atony during convalescence. It is also valuable in neurasthenia and other nervous diseases. Under its influence intellectual activities are strengthened, the will is developed, and sleep becomes normal and refreshing. A moral and physical regeneration occurs. In health, this alkaloid increases rigor and prevents fatigue from muscular exercises.—*Gazette des Hôpitaux*, November 14, 1903.

**Phototherapy as Used by the Chinese in the Treatment of Variola.**—Jules Regnault says that since 1893 we in Europe, thanks to Finsen, have known the value of the red light in the treatment of the eruption of smallpox. The Chinese, who have studied this affection for three thousand years, also know the valuc of red light and apply it in a somewhat original fashion. As soon as the eruption appears, the physician sprays the bed and the patient with arrack, gives various potions as indicated, and then touches the eruptive spots as they appear with a lotion obtained by boiling red pigamon. (Thalictrum rubellum) in water, and throwing into the infusion a handful of cotton impregnated with a red coloring matter extracted from the Carthamus tinctorius. The process is recommended to European physicians in the cases in which it is difficult to obtain the Finsen red room.—*Bulletin Général de Thérapeutique*, October 15, 1903.

**Experimental Atheroma of the Aorta from the Intravenous Injection of Adrenalin.**—O. Josué produced atheroma of the aorta in rabbits by numerous (sixteen to twenty) injections of three drops of a 1 to 1000 solution of adrenalin into the veins. Five or six injections only produced no effect. Nor was there any result from subcutaneous injections. The experiments prove that adrenalin possesses a special toxic power on the arteries, capable of producing atheroma. It may be due to the arterial hypertension induced by each injection, but this the author does not pretend to decide. He calls attention to the fact that adrenalin is a secretion of the suprarenal glands, and that therefore it is within the range of possibility that these organs may play an important rôle in the production of atheroma. The subject deserves further study.—*La Presse Medicale*, November 18, 1903.

**Eberth's Bacillus in the Circulating Blood of Typhoid-Fever Patients.**—Guido Q. Ruata holds that typhoid fever has been proved to be among the general infective diseases, and that it belongs to the lymphatic type; the localization in the intestines being only secondary. The lymphatics nearest to the intestinal ulcers are those presenting the most severe lesions. The mesenteric glands are also swollen. Sanarelli says: "We are now in possession of many facts which show that the Eberth bacillus penetrates into the organism—no matter by what path—and may be carried in the blood or lymph stream, or by the leucocytes, into the spleen and other organs of the lymphatic system, there to gradually produce its poison and initiate that period of propagation and slow general intoxication characteristic of the disease. The intestinal theory of the disease has no longer any reason for existence, and the terms abdominal typhoid, enteric fever, dothi-enteric fever, and ileotyphoid should be abolished.—*Il Policlinico*, November, 1903.

**Abortive Forms of Chronic Appendicitis.**—A. Siredey calls attention to certain symptoms of chronic appendicitis which in themselves do not appear to be very important, but which later may culminate in an acute and severe attack. In children especially should one be extremely watchful and on one's guard. Dyspepsia holds the first place among the symptoms, and may range from simple gastrointestinal atony to the most acute and intense suffering. In women, the symptoms of appendicitis may easily be confounded with those of inflammation of the adnexa. Most persons suffering from chronic appendicitis are thin because of difficulty of assimilation; nearly all have a yellow or earthy coloring. Children sometimes have no symptoms of appendicular trouble, but if observed are seen to become pale at certain times without apparent cause, express a desire to defecate, or have slight vomiting attacks. Especial watchfulness should be exercised when children vomit easily, more particularly when the vomiting occurs after walking, driving, or other forms of exercise.—*Le Bulletin Médical*, November 21, 1903.

**Certain Abuses of Sea-bathing and Sea-air Treatment.**—Henri Lamarque protests against the carelessness shown by many patients who go to the seaside for treatment, plunge into the water without observing the slightest precautions, suffer chills and have no reaction, and perhaps take two baths a day. Moreover, cold bathing is contraindicated in many cases, but no attention is paid to these contraindications. In rheumatism, gout, herpes, cold bathing can only be harmful. Young girls and women often suffer from a form of arthritic trouble which simulates anæmia. There may be amenorrhœa, or dysmenorrhœa, accompanied by nervous conditions, dyspepsia, neuralgia, etc. The cellular tissue is overdeveloped, the venous system is affected, as shown by the appearance of reddish or purple lines on the skin in various situations, and the ready formation of ecchymoses. The uterus will be found to be congested. In these cases sea-baths should be absolutely forbidden.—*Revue Internationale de Thérapie Physique*, October 15, 1903.

**The Nature of Some Forms of Protracted Fever in Childhood.**—G. Myà says that we must always take into account the tendency to high temperatures found in early life, especially in those with a neuroarthritic, syphilitic or tuberculous taint. We must also bear in mind several latent causes of fever, such as coli bacilli in the bladder, and infection of the pharyngeal lymphatics. We should avoid jumping to the conclusion that fevers of unknown nature are of gastroenteric origin, for in childhood the symptomatology of infections and intoxications of alimentary nature are usually very evident. The most frequent cause of fevers without adequate symptomatology is latent tuberculosis, which occurs often in children, and is often arrested if suspected and treated in time. In the face of a persistent and unaccountable fever, after having excluded gastroenteric toxi-infections, from alimentary gastroenteritis to typhoid, dysentery, pyogenous gastritis and enteritis, we should put the child on a nourishing diet and so avert the perils of tuberculosis.—*Revista di Clinica Pediatrica*, November, 1903

# Book Reviews.

A Textbook of Operative Surgery: Covering the Surgical Anatomy and Operative Technique Involved in the Operations of General Surgery. Written for Students and Practitioners by Warren Stone Bickham, Phar. M.D., Assistant Instructor in Operative Surgery, College of Physicians and Surgeons, New York; late Visiting Surgeon to Charity Hospital, New Orleans; late Demonstrator of Operative Surgery, Tulane University, New Orleans. New York, Philadelphia, London: W. B. Saunders & Co., 1903.

This is a comprehensive contribution to the literature of operative surgery, which is welcome, as being most full and precise in the matter of surgical anatomy and of operative technique. The operations of both general and special surgery are considered under the heads of surgical anatomy, landmarks, general considerations, and instruments. In the discussion of the arteries, the first impression obtained is the excellence of the illustrations. The subject of arteriorrhaphy is well discussed and illustrated, but, under the treatment of aneurysm by ligation, one misses any illustration to show the various methods. We note, also, the omission of angiotripsy, or arteriotripsy, no attention having been granted the angiotribe which, in the hands of many operators, now does away with the, older method of vaginal hysterectomy by the clamp described by the author.

In the discussions of the operations upon the Gasserian ganglion, it may be considered by some unfortunate that the technique of Cushing should be omitted. On page 202, in detailing the methods sequestrectomy, Neuber's method of infolding the skin is quoted, but Stimson's well-known views are not cited. On page 391 an opportunity to make clear to the student the exact method of inserting the pins in Wyeth's hip operation is lost. Occasionally throughout the book the lettering on some of the illustrations is not quite heavy enough to be distinct. The discussion of the operation upon the tongue might be open to the criticism that too much consideration is given to the technique of Whitehead's intrabuccal excision, which, in this country at least, is very rarely practised. One apparent omission in this book is that of descriptions of staphylorrhaphy and uranoplasty; they are, at least, not to be found in the index. A good feature of the book is the excellence and accuracy of the cross references.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; one-time Clinical Professor of Diseases of Children in the University of Pennsylvania; Member of the Association of American Physicians, etc. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-Patient Medical Department of the Jefferson Medical College Hospital. Volume III. September, 1903. Diseases of the Thorax and its Viscera, including the Heart, Lungs. and Blood Vessels; Dermatology and Syphilis, Diseases of the Nervous System, Obstetrics. Philadelphia and New York: Lea Brothers & Co., 1903

This issue contains four excellent monographs: that of William Ewart, on thoracic affections; of Gottheil, on dermatology and syphilis; of William G. Spiller, on diseases of the nervous system, and of Richard C. Norris on obstetrics. That of Gottheil is well illustrated and is most instructive, going over the literature of his department in a very painstaking manner. The publishers are to be congratulated on the fruition of their manifest efforts to give their subscribers a year book which reflects the greater portion of the real advances.

L'Ematologia nella Febbre Tipoide. Pel Dott. V. Guidiceandrea, Professore di Patologia Medica dimostrativa nella R. Università di Roma. Roma: Libreria Internazionale Del Policlinico, 1903.

In this volume of over 300 pages many of the most interesting questions connected with the subject of typhoid fever are entered into, especially the conditions of blood and fluids, bacteriology, and the modifications and chemical changes undergone by the blood, under varying conditions, cold baths, etc. The work shows wide personal research on the part of the author and reflects much credit.

Starvation Treatment of Certain Malignant Growths. Samuel D. Gross Prize Essay. By R. H. M. Dawbarn, M.D. Philadelphia: F. A. Davis Company, 1903.

Congratulations are due to Dr. Dawbarn on his excellent contribution to the surgery of malignant disease. The clinical histories recounted by the author easily convince one of the value of complete external carotid excision in inoperable malignant disease of the parts supplied by this vessel and its branches.

We have in these reports another proof of the fact that sarcomata and carcinomata are in their beginnings strictly local diseases; and that they may remain local in character even in their advanced stages. This should stimulate us to continue our teachings that malignant neoplasms in their early stages can be cured, and should encourage us to spread this doctrine amongst the laity.

The final portion of the author's essay is devoted to a study of the plugging of the terminal and occipital branches of the external carotid, with the idea of still further preventing anastomotic circulation. To inject into these arteries a plastic material, over the ultimate destination of which in the circulatory system we have absolutely no control is unsurgical and unsafe. The existence of an anomalous anastomosis between the occipital or terminal external carotid branches and the internal carotid system, and which is not in our power to ascertain, exposes the patient to cerebral embolism and death from such an injection.

External carotid excision is an excellent procedure, and one of value; the supplementing it with plugging of the occipital, temporal and internal maxillary arteries is unsurgical, because we cannot control it, and consequently dangerous, as the author's cases amply testify.

A System of Physiologic Therapeutics. A Practical Exposition of the Methods, other than Drug Giving, Useful for the Prevention of Disease, and in the Treatment of the Sick. Edited by Solomon Solis Cohen, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College; Physician to the Jefferson Medical College Hospital, and to the Philadelphia. Jewish and Rush Hospitals, etc. Volume VIII, Rest, Mental Therapeutics, Suggestion, by Francis X. Dercum, M.D., Ph.D., Professor of Nervous and Mental Diseases in the Jefferson Medical College of Philadelphia, Neurologist to the Philadelphia Hospital, Consulting Physician to the Asylum for the Chronic Insane at Wernersville, Consulting Neurologist to the St. Agnes Hospital, Consulting Neurologist to the Jewish Hospital, etc. Philadelphia: P. Blakiston's Son & Co., 1903.

The subject of this volume is one of great importance to physicians practising in busy centers. Rest is an agent often neglected in modern therapy, though understood better than formerly. Systematic rest cure is here systematically considered. While not neglected, medicines have been given only secondary importance. Chronic neuroses, neurasthenia, hysteria, hypochondria, chorea, prophylaxis of insanity, and special forms of mental disease have been considered in relation to this form of treatment with its various modifications, Normal suggestion, and suggestion of mystic and religious methods are two interesting chapters ending the volume. The work is well written, and the author shows a wide range of knowledge and observations brought to bear upon the preparation of the work.

High-frequency Currents in the Treatment of Some Diseases. By Chisholm Williams, F.R.C.S., Edin., Member Royal College of Surgeons, etc. London and New York: Rebman Company, 1903.

This may be said to be the first work in the English language that gives anything like an adequate idea of the subject. We have had a good French monograph, and chapters in foreign and domestic works, but the latter have usually been inadequate. Williams presents the subject in an attractive and not over-elaborate or deep manner. His therapeutic claims while not unreasonable are often not convincing. The type is large and much paper space goes to waste, so that in his 218 pages there is not more reading than one can do in an evening. The title indicates the author's belief that while useful in *some*, these currents must not be thought applicable to *all* diseases.

The Four Epochs of Woman's Life. By Anna M. Galbraith, M.D. Second Edition. Philadelphia, New York, and London: W. B. Saunders & Co., 1903.

This little volume was so well received when it first appeared that it is not surprising that a second edition should have been needed within two years. This has afforded an opportunity to add three new sections, viz., one on "The Hygiene of Puberty;" one on "Hemorrhage at the Menopause, a Significant Symptom of Cancer," and one on "The Hygiene of the Menopause." The author starts out with the motto, "Ignorance is the curse of God," and then gives an introductory chapter on "Education as the Controlling Factor in the Physical Life of Woman." The four epochs, maidenhood, marriage, maternity, and the menopause, are all discussed in a practical, common-sense manner, and with rare good judgment.

SECTION ON PEDIATRICS.

*Stated Meeting, Held November 12, 1903.*

HENRY HEIMAN, M.D., CHAIRMAN.

**Myelogenous Leukæmia.**—Dr. EDWARD MILLER presented a boy of eleven years having a negative family history. When first seen on September 11, 1903, he was suffering from diarrhœa, and the abdomen was distended. Following an operation for adenoids a few months ago, there had been troublesome bleeding, but this was the only history of hemorrhages. A year and a half ago it was noticed that the child was becoming pale and that the abdomen was large. Examination showed the child to be well nourished and only moderately anæmic. The abdomen was distended, and the superficial veins dilated. The spleen was enlarged, extending from the seventh rib in the axillary line to the crest of the ilium. The examination of the blood showed hæmoglobin 63 per cent., the red cells 3,976,000, and the white cells 432,000. There were 2.6 per cent. eosinophiles. On September 9 a loud cystolic murmur developed. A more recent blood examination showed hæmoglobin 54 per cent., red cells 3,232,000, and white cells 347,400. The differential count showed polynuclear nutrophiles 16.4 per cent., and eosinophiles 4.8 per cent. The patient had now been on Fowler's solution of arsenic for about a month.

Dr. D. S. D. JESSUP said that this was the first case of myelogenous leukæmia that he had seen in a child. The condition of the red-blood cells was very much the same as in adults. The proportion of eosinophiles was within the normal limits. The mast cells made up 10 per cent. of the number of white cells. The polynuclear nutrophiles ran from 60 to 65 per cent., which was higher than the average found in the myelogenous leukæmia of adults by 10 or 15 per cent. The myelocites constituted about 10 per cent., whereas 36 per cent. was the average in adult cases.

**Nodular Tuberculosis of the Skin. (Erytheme Induré of Bazin.)**—Dr. L. E. LAFETRA presented a boy of two years whom he had first seen last June. In November, 1902, the child was circumcised, and five weeks later a swelling appeared on the middle phalanx of the ring finger of the left hand. Shortly after this a red spot appeared upon the right cheek, and subsequently ulcerated. There had been no night sweats or obvious fever. Examination showed bronchitis and slight enlargement of the liver and spleen. The examination of the eyes for tubercles was negative. On the face were two bluish patches, one on either cheek. The one on the right side was discharging thin serum. Similar nodules, evident on palpitation, were found on the skin of the legs, particularly of the back and sides of the calves. In most places the skin over the nodules was bluish. On July 8 the dactylitis became fluctuating, and the examination of the evacuated pus was negative. On September 29 there was a mass on the left hand removed for examination; this showed a few tubercle bacilli.

Dr. HENRY KOPLIK said that these cases were quite rare here, although he had seen such a case recently in his hospital ward. If such a case were described as tuberculosis of the skin and glands, and dactylitis, the condition would not be so well described as if it were spoken of as scrofulosis.

Dr. JACOB SOBEL said that he had seen several such cases in this country, but not before in a child. The disease was more common in young women than in men. As a rule, the affection involved the lower third of the calf, whereas in the case under discussion the lesions were scattered over many other parts. The condition must, of course, be differentiated from erythema nodosum.

Dr. LAFETRA said that in searching the literature the youngest patient so affected that he could find reported was a boy of about nine years. It was a more common affection in young girls. particularly those who stood a good deal. One of the names for this disease was scrofulous gumma, and this was certainly a very expressive term. In only one other case had tubercle bacilli been found, although tuberculous tissue was usually present.

**Congenital Heart Disease.**—Dr. HENRY HEIMAN presented this patient, a little girl showing a marked bluish tint, and well-marked clubbing of the fingers. The dulness, so characteristic of the pulmonary stenosis, was best noted over the second interspace.

**The Constituents of the Layers of a Quart of Milk.**—Prof. JOHN S. ADRIANCE discussed this topic. He said that if sugar, fat, or proteid material were oxidized the result would be the formation of heat, the degree of which would vary with the ingredient oxidized. The heat produced by the oxidation of fat was about two and a half times greater than that produced by the oxidation of the other two food ingredients. The inorganic matter underwent no change. Milk contained all of the necessary food constituents.

The milk coming to this city could be divided into three classes: (1) That containing a little over the legal requirement of fat, 3 per cent.; (2) that containing between 4 and 5 per cent., and (3) that containing 5 per cent. or over. The best milk delivered in this city was at least sixteen hours old. The proteid material was not in true solution. The milk, when delivered to the consumer, had undergone some change. This change was the rising of the lighter material, the fat; in other words, the fat was held there only by surface tension. A bottle of milk contained at the top a layer composed of a large amount of fat. This layer was approximately the same from day to day. On analyzing this layer it was found that it contained nearly all of the fat of the milk. Most books stated that the composition of cream was the same as that of the milk except that it contained more fat, but, as a matter of fact, the proportion of sugar, proteid, and inorganic matter in the cream was much less than in the original milk, because everything else was pushed out as the cream rose. The composition of the milk examined by him was, fat, 5.02; sugar, 4.82; proteids, 3.56, and ash, 0.74. The proteid material was held there in combination with inorganic matter. The first ounce gave the highest percentage of fat. The ninth ounce contained practically 1 per cent. of fat, and this amount remained nearly the same until the fifteenth ounce was reached, which was found to contain 0.4 per cent. less than the first ounce. The last ounce contained less fat, and, hence, a larger amount of all the other constituents; in other words, the skimmed milk contained a higher percentage of proteid than the original milk. By proteid material was meant organic matter containing nitrogen in such a form that it could be utilized by the body. The point which the speaker especially emphasized was that the proteid material was decreased as the fat content increased, and that the inorganic salts which were necessary for the bony structures of the body, were likewise decreased.

**The Function of Maternal Milk in Developing the Infant's Stomach.**—Dr. HENRY D. CHAPIN read a paper with this title. (See page 921.)

Dr. ROWLAND G. FREEMAN said that all should feel indebted to Dr. Adriance for his careful work on the composition of the different layers of milk. The question arose as to whether this exposition would alter at all our methods of modifying milk. For practical purposes, he thought we could go on modifying milk as heretofore, such deviations as had been pointed out being lessened by the dilutions employed. Growing experience with the modification of milk had impressed most physicians with

the fact that small deviations were not of much practical importance. In his hospital work he had found the house physicians disposed to use too low formulas for feeding. Such formulas were of the greatest value for short periods, but should not be kept up long. In using cow's milk, it could be fairly well adapted to the infant's stomach by extracting the whey, thus obtaining a lactalbumin milk, which would often be well digested by infants who could not digest ordinary cow's milk.

Dr. H. KOPLIK said that Dr. Chapin had made the statement that colostrum had a distinct cathartic function, and this might be true of the lower animals. The textbooks handed down the statement that the colostrum, as such, had a cathartic function, but he had been unable to find any recent scientific data on which to find such a statement. It was not uncommon for the new-born infant to be constipated, and, in any case, the quantity of colostrum taken by the infant would seem to be too small to produce catharsis unless the colostrum possessed very cathartic properties. The statement had also been made in the paper, that as the child grew older the number of feedings were reduced naturally because of the increasing quantity of milk secreted. There were two sets of observations for determining the quantity of milk that the human breast would deliver. In one set the quantity was found to remain about the same from the second month to the time of weaning. In the other set, the quantity of breast milk increased gradually from birth to weaning. Dr. Chapin had made the statement that the milk adapted itself to the infant's stomach, and the infant adapted itself to the milk, but to this statement he would take exception, because cases occurred in practice which seemed to negative this view. The proteid of cow's milk should be adapted to the baby's stomach, but it must be remembered that it was not at all the same proteid in cow's milk as in breast milk. Sixteen times as much phosphorus was voided by a baby fed on cow's milk as by one fed at the breast. There was no hard and fast rule for infant feeding, and we were not yet prepared to say how or why food was digested and assimilated.

Dr. JOSEPH E. WINTERS said that in the summer of 1898 he had consulted Professor Adriance with regard to milk analysis, stating that he was confident, from clinical work, that the upper layers of cream contained a very small quantity of proteid. Professor Adriance replied that, according to all analyses, the upper layer contained the same quantity of proteid as the rest of the milk. At the request of Dr. Winters Professor Adriance made a series of milk analyses. Another series of analyses was made by Dr. Lederle, and still another by Mr. Henry C. Sherman of Columbia University. The milk supplied for these analyses was all from the same source, and the milk was not over sixteen hours old. He was glad that the results presented this evening by Professor Adriance fully confirmed his own views of five years ago, based entirely upon clinical observation. Whenever there was a diminution of the proteid there was a corresponding diminution of the inorganic constituents, because as the cream rose there was less of the proteid, and as the proteid diminished, the inorganic salts necessarily diminished. The reduction of the proteids of the food for a long period always meant the development of rickets. He would even go so far as to assert that it was the only cause of rickets. Lime-water had been added to milk in the proportion of one-quarter for a great many years by those who had been most successful in the feeding of infants, but it was not done to render the milk alkaline. In the summer the proportion of lime-water should be greater than in winter, and should preferably be one-fourth the quantity of milk.

Dr. HENRY L. COIT of Newark, N. J., said that his experience had taught him that every baby's stomach was a law unto itself. It had taken him ten years to learn how to individualize the feeding of infants, and, he thought, with most physicians this became eventually largely a matter of intuition rather than of the precise application of scientific rules. He had had twenty-two analyses of milk made at the twelve-ounce line, and nineteen of these gave 10 per cent. The lower down one examined the milk in the bottle the more uniform would the fat percentage be found. He was not yet convinced that proteid indigestion was the most important obstacle to success in infant feeding, being rather of the opinion that the digestion of cow casein had not received sufficient attention.

Professor Adriance, in closing, said that as the fat increased the other ingredients decreased, but that the ratio was not uniform for these other ingredients. Of course, as milk was diluted more and more the error became less. The physician should, however, aim at accuracy, because clinicians had learned that a difference of even one-fourth of 1 per cent. of proteid exerted an appreciable effect upon the infant's digestion. Some years ago he had shown that the percentage of proteid in cow's milk was not 4, as usually stated in the books. Richmond of England, as a result of thousands of analyses of milk, had confirmed this statement, and had declared that the proteid of cow's milk was ordinarily only 3 to 3½ per cent.

Dr. Chapin said that a very rich milk creamed differently from milk not so rich, and he was inclined to think that if Professor Adriance had taken an average milk, having a fat content of 3 to 3½ per cent., the figures would probably have been different. Moreover, he had given us the results of only one assay, and although no doubt this was most accurate, it was still only one assay. Again, it was much easier to assay the butter fat than the proteid, and even expert chemists were not always entirely agreed as to the method of estimating the proteids. It should not be forgotten that the proteids of milk were quite complex, and that some of them had very different functions from the others. The idea of using lactalbumin had been referred to, yet he did not believe the theory was correct. It had been found that nucleoalbumin was required; the phosphorized albumins had a different nutritive value. It was known that infants could be starved on these phosphorized albumins; nature craved nucleoalbumin for the building up of tissue. The longer milk was kept the more albumoses and peptones would be present. All these facts showed how complex was the subject, and how improper it would be to take such a table as that presented by Professor Adriance and use it as a basis for generalization. He thought that Dr. Koplik had misunderstood him, for he had not stated that the bulk of the milk varied much, but rather that the infant's digestive secretions varied. He believed this whole subject should be studied more from a biological than from a chemical standpoint.

## NEW YORK ACADEMY OF MEDICINE.

### SECTION ON OBSTETRICS AND GYNECOLOGY.

*Stated Meeting, Held November 27, 1903.*

L. J. LADINSKI, M.D., CHAIRMAN.

**French Instruments for the Production of Abortion.**—Dr. FREDERIC GRIFFITH exhibited a number of instruments that he had collected in Paris, where they were sold in the market places, and were intended for the production of abortion.

Dr. H. J. BOLDT presented a number of specimens and reports of cases.

**Myofibroma with Pregnancy; Cæsarean Section.**—The first specimen was a myofibroma of the uterus, which had complicated pregnancy, and had been associated with symptoms simulating those of ovarian tumor with twisting of the pedicle. The patient was a woman of thirty-five, married ten years, and the mother of four children. Soon after her last confinement, two years ago, it was said, she had been examined by two prominent gynecologists, who had diagnosticated an ovarian cyst. This was also the diagnosis of the family physician at the time of calling in Dr. Boldt. When seen by him she was seven months

regnant, and had been well up to the night before, when he was suddenly seized with intense abdominal pain. This was accompanied by a pulse of 120 and a temperature of 100.5° F. Examination showed a large tumor filling the abdomen up to the umbilicus, and pushing the pregnant uterus upward and backward. A diagnosis of ovarian tumor with a twisted pedicle was made, but on opening the abdomen the tumor was found to be a myoma in the lower segment of the uterus. Cæsarean section was done, and resulted in the delivery of twins, each having a separate placenta. The vagina not having been prepared, it became necessary to do a supravaginal instead of a panhysterectomy. The adnexæ were left. The infant lived an hour and the other for three days. The mother made a good recovery. The symptoms in this case seemed to point very strongly to the twisting of the pedicle of an ovarian tumor, and in the light of the operation he was unable to explain these symptoms.

**Fibrocyst of the Uterus; Total Hysterectomy by Unusual Technique.**—This specimen had been taken from a single woman, aged forty-seven years, whose principal symptoms were flatulence, emaciation, sharp pains in the thighs, and abdominal enlargement. Exceedingly extensive and firm adhesions were encountered at the operation, especially in connection with the ascending colon and the sigmoid flexure. The colon was spread over the tumor in such a way that the bowel must have been almost occluded, yet the history only noted ordinary constipation. As it was impossible to separate the intestinal adhesions without severe and extensive injury to the bowel, the operator first freed the uterus below, and then turned it upside down, thus reversing the usual mode of approach. A part of the mesentery had to be sacrificed during the separation. The cyst measured five inches in the anteroposterior diameter, five and three-fourths inches laterly, and twelve inches from base to apex. The recovery of the patient was interrupted by a bronchopneumonia, probably caused by the ether. The chief practical interest of this case centered in the unusual technique by which seemingly insurmountable difficulties were overcome.

**Ovarian Cystoma; Twisted Pedicle; Absence of Peritonitis.**—The next specimen presented had been taken from a woman of thirty-five, the mother of seven children. Her last confinement had occurred ten months previously. The woman complained chiefly of abdominal pain, which had increased in severity during the previous week. The pain was referred to the left iliac fossa. The diagnosis was ovarian cystoma of the left side with twisting of the pedicle. On operating, an ovarian tumor, 11 inches in diameter, was exposed. The pedicle was twisted four and one-half times from left to right. According to the history, the twist must have been present several days, and gangrene of the tumor was well advanced, but there was not the slightest evidence of peritonitis.

**Cancer of the Sigmoid Flexure.**—This specimen was removed from a patient, thirty-seven years of age, who had been ill six months with constant cramp-like pain in the lower part of the abdomen. She was obstinately constipated, and the stools usually contained blood. The physician who had treated her made a diagnosis of an ovarian tumor pressing upon the bowel and producing an ulcer of the intestine. Examination showed that the neoplasm was in the bowel and lying near the uterus. The diagnosis of neoplasm of the lower part of the sigmoid flexure was confirmed by operation. The bowel, with as much of the mesentery and glands as were diseased, was resected.

**Ovarian Fibroma; Symptoms Caused by Appendicitis.**—The patient was a single woman of twenty-five, who had been complaining for nine years of dysmenorrhœa and pain in the right iliac region. The pain in the right iliac fossa was constant, and at times so intense as to prevent her from following her vocation. The ovarian fibroma could be readily felt on examination, but was not specially sensitive on pressure, and what little discomfort was produced in this way was not like the constant pain of which she complained. On the other hand, when even slight pressure was made over the region of the appendix the pain of which she constantly complained was greatly aggravated. For these reasons a diagnosis was made of chronic appendicitis. At the operation the appendix was found in a condition of subacute catarrhal inflammation. The speaker said that he had seen a number of instances in which a similar error in diagnosis had resulted from the fact that the examining physician ferred fromily feel prolapsed and cystic ovaries, and incould read this that they were the cause of the distress.

**Adenocarcinoma of the Body of the Uterus; Abdominal Hysterectomy without Ligature or Clamp.**—Dr. Boldt reported the following case: He said that it was, perhaps, unique to have the abdominal contents so matted together that an abdominal operation could, and had to be performed without resorting to either ligature or clamp. The patient, a woman of fifty-five years, was the mother of two children, the last one having been born thirty-three years before. Menstruation had ceased several years before, but there had been an atypical flow during the past two years. Not infrequently a good deal of blood had been passed per rectum. For the past six weeks she had suffered severely from rectal tenesmus and abdominal cramps. Under ether it was found that there was an enormous fecal impaction high up in the bowel. At the first examination, without an anæsthetic, this mass was so firm that it was diagnosed as an incarcerated fibroid. After much difficulty the fecal impaction was finally dug out piecemeal. Curettage was then done for diagnostic purposes, and the material so removed was reported by Dr. H. T. Brooks to be an adenocarcinoma. Because of the large size of the uterus, its extreme relaxation, the narrowness of the vagina and the likelihood of their being some retroperitoneal glands requiring removal, the abdominal route was chosen, although the patient weighed about 250 pounds. After opening the abdomen, the omentum was found to be firmly adherent to the intestine and much thickened. The coils of intestine were so intimately adherent to one another, to the parietal and to the pelvic peritoneum, that it was impossible to separate all the adhesions. The dark red appearance of the bowel seemed to indicate an acute inflammation, but the firmness of the adhesions negatived this view, so the color was probably dependent upon chronic congestion. It took fully half an hour to locate the uterus. After reaching the fundus it was found so tightly embedded in adhesions that abandonment of the operation was considered. The intestine tore whenever a little more force was used in separating adhesions, so that several intestinal sutures were necessary. So intimate and firm were the adhesions that it was impossible to use either ligature or clamp. Working along the posterior surface of the uterus the floor of the pelvis was reached, and then with the fingers hugging closely the uterus so as to cause no further injury to the intestines, the right parametrium was approached and manually separated from the uterus from behind forward. The bladder could not be seen, but was separated from below upward. The parametrium on the left side was then approached from its anterior surface, and separated as had been done on the right side. Thus, the organ was finally extirpated. The free oozing was controlled by tamponing the pelvis with iodoform gauze, and the abdomen was closed. The first dressing was changed on the fifth day. Recovery was interrupted by a large abscess in the adipose tissue of the abdominal wall, and the woman had hallucinations and delusions for two weeks after the operation. It was subsequently learned that she had had an attack of general peritonitis fifteen years before, but this would hardly explain the condition found at operation. The state in which this woman's abdomen was found was almost incredible, and it was wonder-

ful that she recovered from the operation. She was now well, except for constipation.

Dr. GEORGE H. BALLERAY presented a number of specimens, as follows: Two specimens removed by vaginal hysterectomy from women, forty-four years of age, for procidentia. The tubes and ovaries, removed from a woman of thirty-six who had pyosalpinx and ovarian abscess, were also shown. In this case the woman nearly died under the anæsthetic. The pulse kept rapid, and there were vomiting and abdominal distention for three or four days after operation. On the fourth day the pulse became exceedingly rapid. The speaker was of the opinion that these symptoms were dependent upon implication of the pneumogastric nerves.

The next specimen was a uterus removed from a woman of thirty-five, because of excessive hemorrhage at the menstrual periods. All the usual medicinal measures, as well as tamponing, had been tried without avail.

The other specimens were, a multilocular cyst which had contained forty pints of fluid; a monolocular ovarian cyst which had contained fourteen pints of fluid, about three pints of which were pus, and an appendix.

Dr. S. MARX said that in cases of procidentia he did not think relief was afforded simply by removing the uterus. After such an operation there was apt to be much subsequent distress from prolapse of the vagina, bladder, and rectum. For this reason he had, in the past two years, a abandoned this method of operating.

Dr. P. A. HARRIS said that he agreed with the last speaker. He preferred to do an abdominal hysterectomy, leaving the cervix and sewing the latter into the musculature of the abdominal wall. This operation had given him considerable satisfaction.

Dr. A. STURMDORF said with regard to the case reported, in which vomiting, intestinal symptoms, and rapid pulse followed operation, that those who would make it a routine practice to examine the urine after operation would be surprised to find how many cases of acute nephritis, due to ether, developed at this time. Sometimes these symptoms were, of course, due to sepsis.

Dr. BALLERAY said that he had not hesitated to do vaginal hysterectomy in his case of procidentia, because the patient was past the child-bearing period. He could recall only a single case of this sort in which there had been prolapse of both the anterior and posterior vaginal wall of sufficient extent to demand a subsequent operation. In that case he believed this result was due to the house physician's having allowed the patient out of bed at the end of two weeks instead of keeping her in bed for four or five weeks. In the case of vomiting and rapid pulse reported by him, the urine had been examined daily for several days after the operation, but had failed to show the presence of nephritis.

**Tubal Pregnancy.**—Dr. P. A. HARRIS presented specimens from three cases of tubal pregnancy. The first was a tubal pregnancy operated upon before the fœtus had escaped from the tube. The patient was a woman of forty, the mother of four children, the youngest being sixteen months old. On June 17 she had a slight chill and a severe attack of pain in the hypogastric region. There was a good deal of tenderness on the right side of the lower part of the abdomen, and although the colic ceased the soreness continued for three or four days. There was a second attack of abdominal colic on June 27, which passed off in three or four hours. The next morning the pain was agonizing, necessitating the use of morphine. After another day of pain she did fairly well until seen by Dr. Harris on July 11. She then stated that ten days before the first attack of colic she had had a rather prolonged and profuse menstruation. Examination showed enlargement and tenderness of the right tube. A diagnosis of tubal pregnancy was made, and operation was done.

The other two cases were examples of quite advanced extrauterine pregnancy with severe internal hemorrhage. The first of these patients was a colored woman, twenty-six years of age, the mother of two children. Preparations had been made for operation immediately upon her arrival at the hospital. On admission, her pulse was so weak and rapid as hardly to be counted. and the slight delay necessitated by her refusal to submit to operation until the arrival of her husband was sufficient to so aggravate her condition that it was deemed best to postpone the operation long enough to give a saline infusion of 425 c.c. in the median basilic vein. This improved the pulse so that it could be counted, and, accordingly, the abdomen was opened. Quarts of clotted and fluid blood were turned out along with the fœtus and placenta Following the operation she was given an infusion of 650 c.c. saline solution. She made an excellent recovery.

The second patient was a woman of thirty-four, the mother of one child, eleven years old. Menstruation had been regular up to and including February, 1903. On March 8 there was some bleeding accompanied by severe pain in the hypogastric region. There was no more bleeding until March 22, but from that time on there was more or less "spotting" until April 8. On that day she had an attack of severe abdominal colic, and a fainting spell, and for many days thereafter the abdomen remained excessively tender and she suffered at intervals from cramp-like pains. It was learned that on April 7 she fell from a step-ladder and struck the lower part of the abdomen. A local physician considered the attack on April 8 a miscarriage, and attended her for two weeks, but she did not miscarry. She did fairly well until July 16 when another seizure led her to call Dr. Stinson. Her pulse then was 90 and temperature 97° F. He diagnosed tubal pregnancy and internal hemorrhage, and urged her to go to the hospital. Six hours later her condition was so bad that she consented to be removed, but she died just as she was being taken from the ambulance.

**Toxæmia of Pregnancy.**—Dr. WILLIAM S. STONE was the author of this paper. He said that a review of the textbooks on obstetrics indicated that hyperæmesis gravidarum was, in most cases, a reflex neurosis, or a form of toxæmia of unknown origin. In two-thirds of the cases there was increased irritability of the medullary centers, due to circulatory disturbances or toxic elements circulating in the blood. The literature was reviewed, and the author's own three cases reported. One of the cases was interesting because of the character of the vomited matter. It contained bile, blood, and epithelial cells from the stomach, and corresponded with what was known as "black vomit." In another case the symptoms all became very much worse after emptying the uterus; the urine contained numerous casts and large quantities of albumin, and in forty-eight hours the patient died in coma. The autopsy in this case was complete, and, so far as he knew, was only the second one on record in which the autopsy was complete. The condition of the liver, as well as the clinical course, corresponded very closely with acute yellow atrophy of the liver. The stomach and intestine were normal, and the coffee-grounds matter in the stomach was proved to contain blood The author concluded that nausea and vomiting were not physiological, but pathological accompaniments of pregnancy.

Regarding eclampsia, it was stated that the temperature might be normal or high, and that jaundice might or might not be present. Eclampsia occurred without albuminuria in one-tenth of the cases. There was a rapid disappearance of the albuminuria in many cases in which severe lesions of the kidneys were found. The kidney lesions varied from those of nephritis to degenerations like those in the liver. Eclampsia was now generally recognized as a toxæmia, the chief lesions of which were necrosis and multiple hemorrhages in the liver. The liver, in fatal cases, might show simple cloudy swelling, chronic congestion, acute yellow atrophy of the yellow or red stage. In eclampsia there were multiple miliary necroses or hemorrhages. The gall-bladder usually contained an abundance of bile. In grave conditions, marked by

black vomit, there must be very severe degeneration and some necrosis to account for the color of the vomitus. The moderate, uniform fatty degeneration commonly observed in the liver of pregnancy must stand as the anatomical basis of the toxic symptoms noted in the mild cases. In all cases the renal lesions appeared to be less severe and secondary to those of the liver. The kidney was often normal while the liver was diseased, yet a diseased kidney and a normal liver were never observed in these cases. There seemed to be no escape from the conclusion that pregnancy itself was an autointoxication. The pulse was ordinarily the best indication of the condition of the patient, although taken by itself it might mislead the physician. The character of the vomitus was of even greater importance; it was usually almost colorless mucus, changing in the severe cases to thin and brackish fluid in larger quantity. The urinary changes were a good guide in some cases. Albuminuria in slight amount was probably always present, but, by itself, was of greater significance when present in the earlier months of pregnancy. The presence of blood and casts in the urine, and the increase of certain normal ingredients, and the presence of leucin and tyrosin and bile were of the greatest importance in connection with the diagnosis and treatment. The presence of cerebral symptoms, convulsions and coma, except in the eclamptic type, denoted such severity that efforts at treatment were of no avail. It was most important to recognize the toxæmic origin of these symptoms, and the influence of various hereditary disorders. The treatment of the severe cases should be that recognized as best for eclampsia. We should limit our efforts to calomel, salines, and a few similar well-known and tried measures. In some cases it was well to try gastric lavage once or twice if vomiting were obstinate. The chief reliance should be on the frequent use of saline injections into the rectum, or continuous irrigation with hot saline solution. The direct injection of saline solution into the cellular tissue or into the veins was sometimes of service. It should not be forgotten that the injection of premature labor was often futile as regards the control of vomiting; indeed, in the later stages this procedure often only served to precipitate the fatal issue. It should be especially noted that urinary troubles often failed to make their appearance until very late in the disease. The speaker thought it was proper to terminate pregnancy when black vomiting appeared, or still better to do it at a somewhat earlier period.

**Significance of Albuminuria in Pregnancy.**—Dr. CHARLES JEWETT said that the keynote of the paper was the proposition that the underlying cause of most of the disorders peculiar to the pregnant state was toxæmia. We were greatly indebted to the reader of the paper for bringing out this theory so prominently, for it was certainly very important, and opened up a field for investigation and emphasized a new treatment. Some years ago Dr. Montgomery Crockett had contributed a chapter to a work on obstetrics in which he had taken this view. The speaker said he believed that it was still an unsettled question as to what was the nature of the toxæmia, whether it was due to a lesion of the liver, to intestinal putrefaction, or whether the poison was partly derived from the fetal products of gestation. It was the custom of most writers to belittle the importance of albuminuria as evidence of danger in pregnancy, and yet he believed it was of great value, although all knew that an albuminuria did not necessarily mean eclampsia and that eclampsia might occur without albuminuria. In the presence of albuminuria, however, the patient was never safe. If the quantity of urine and the quantity of total solids were ample, the patient was safe so long as no nervous symptoms developed; but such cases required the closest supervision. The quantity of urea seemed to him an over-rated danger signal of the re-eclamptic stage. If the urea were estimated daily in half a dozen cases the results would be found to vary widely. Moreover, the quantity of urea would vary a good deal with the quantity of nitrogenous food taken, and it should not be forgotten that the quantity of urea was ordinarily diminished in the later months of pregnancy. He had frequently seen cases in which the urine was very much diminished, and yet the patient evinced no evidence of illness, and went on safely through her labor. Mention was made of a case of eclampsia in which the patient passed over 100 ounces of urine for several days after labor, and then developed a severe eclamptic attack, which was finally controlled and the patient started on the road to recovery by the introduction through a stomach tube of a large dose of calomel and Epsom salts. The interesting feature was the large quantity of urine passed, but this was explained by the drainage of the œdematous tissues of the body without much elimination of the urinary solids.

Dr. MALCOLM MCLEAN said that inasmuch as the function of the liver was always very decidedly disturbed in cases of seasickness, he desired to call attention to the fact that a lady who had previously crossed the ocean eight times without being seasick, even in stormy weather, crossed the ocean when pregnant four months. She almost immediately developed a most pernicious vomiting, became extremely toxic, and was taken from the ship at the end of the voyage almost moribund.

**Diminution of Urea an Index of Danger.**—Dr. S. MARX said that he could readily understand that a hysterical condition might give rise to hyperæmesis of sufficient gravity to worry the relatives and lead the physician to induce abortion. Antecedent stomach disease was of the greatest importance in connection with hyperæmesis gravidarum. He treated these women as if they were not pregnant, but the victims of a very serious stomach disorder, such as gastric ulcer. He kept them quiet on liquid food, and gave them at a dose nearly a tablespoonful of subnitrate of bismuth. The more he made urinary examinations of pregnant women the less he thought of albuminuria as an index of danger, and the more he thought of the quantity of urea. He did not mean by this that urea was necessarily the element of danger, but he had never yet seen a case of eclampsia or a severe case of eclamptic toxæmia in which the urea was not diminished. On the other hand, he was free to admit that he had seen cases in which the quantity of urea had been so much diminished as to make him very anxious, and yet eclampsia had not developed. It was quite possible that we did not know what was the normal output of urea, but whenever the quantity of urea progressively diminished it should be taken as an indication of serious danger.

**Vomiting of Pregnancy of Two Kinds.**—Dr. E. B. CRAGIN said that the more one saw of obstetrics the more respect one had for toxæmia. We should look upon the vomiting of pregnancy as of two kinds, the later and the earlier. Severe vomiting in the later months of pregnancy almost always indicated a severe toxæmia, usually a liver toxæmia. He was not prepared to say that the early vomiting of pregnancy was always due to toxæmia, for there were so many changes in the pelvic organs which might produce nausea and vomiting in the non-pregnant that he was inclined to think that it might give rise to such symptoms in the pregnant. Again, if all such cases of vomiting were due to toxæmia he found it difficult to understand why that vomiting should cease spontaneously later on in pregnancy when the products of the fœtus were tending to increase the toxæmia. The only two fatal cases of toxæmia of pregnancy occurring in the past year at the Sloane Maternity Hospital were of the liver variety, *i.e.* acute yellow atrophy. Four cases of toxæmia of pregnancy, three of them eclamptic, at this hospital were reported by the pathologist to be cases of acute yellow atrophy of the liver.

Personally, he believed there was only one way of treating a severe case, and that was by emptying the

uterus before the severe symptoms developed. He would admit that sometimes this procedure only hastened the fatal termination, but not infrequently these patients improved after evacuation of the uterus. He had just such a case at present in his wards, emphasizing the improvement that sometimes followed, even in very severe cases, from prompt emptying the uterus before the supervention of severe symptoms.

With regard to urea and albumin as indices of eclampsia, he would admit that neither the diminution of the urea or the presence of albuminuria necessarily meant that eclampsia was imminent. He had seen a number of cases in which there was great diminution of the urea, and yet the patients presented no symptom of toxæmia. He believed, with Dr. Jewett, that albuminuria was not necessarily an indication of toxæmia, but that it should be looked upon as an important danger signal, and that by grasping the whole clinical picture one could arrive at a correct diagnosis. The treatment outlined in the paper was the one which he would indorse.

Dr. S. W. BANDLER regretted that the author of the paper had laid so much emphasis upon what he called "liver toxæmia," for this term would tend to blind us as to the true nature of the condition. The brain, the heart, the spleen, the pancreas, and other organs of the body were known to participate in this process, thus indicating that there was circulating in the blood certain toxins, but gave us no clue as to the origin of these toxins. In the opinion of the speaker, the important point to consider was the origin of toxins from the fœtus or the placenta. He believed that these toxins were given off by the placenta. As to why the placenta should do this in some cases of pregnancy and not in others, he said that microscopical examination showed no difference in the structure of the placenta in the toxæmic and in the normal cases of pregnancy. We knew what too little or too much thyroid or other internal secretion would do; hence, he saw no reason why grave consequences should not follow a diminution or an increase of the placental secretion.

Dr. STONE, in closing the discussion, said that one of the chief objects of his paper was to try to interest the profession in making more exact and exhaustive reports of these cases of hyperæmesis gravidarum.

## THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

*Stated Meeting, Held November 23, 1903.*

WENDELL C. PHILLIPS, M.D., PRESIDENT.

**President's Inaugural Address.** — Dr. WENDELL C. PHILLIPS delivered this address. He said that during the ninety-eight years of the society's existence sixty-five men had been elected to the presidency, one holding office for a period of seven, and another for five years. The first president, Nicholas Romayne, took office in 1806. The society had always taken a strong position upon all questions relating to the public health, sanitation, the enacting of medical laws and efforts to raise the standard of medical education. It was decided that there should be a just and equitable state law to determine the qualifications of those who desired to enter the medical profession of this State, and through the efforts of the State Society, influenced by the medical sentiment of New York City, such a law was enacted, but only after a revision of the Code of Ethics, chiefly in the matter of freedom in consultation with all legalized practitioners of medicine. This action was not taken primarily to obtain liberty to consult with homœopathic practitioners, but to secure their coöperation in bringing about the passage of this law, which was considered paramount even to any code of medical ethics. The result has been so satisfactory that Pennsylvania, Virginia and Illinois, and finally all the States of the Union, as represented in the American Medical Association, had, after twenty years, vindicated the action taken by the Medical Society of the State of New York by abolishing from its by-laws and constitution the code of ethics so long maintained. A harmonious union of the medical profession of this State was now being attempted, and it was hoped that a successful issue would be consummated.

Reference was then made to the good work done by the Milk Commission and by the legal department of the society. The work of the latter had been recently set forth at some length by the counsel, who declared that "The County Society has become a terror to evil doers." A notable instance of the success achieved in this field was the exposure of a so-called Lung Cure, but even the society's best efforts were not sufficient to keep pace with the offenders. It was most unfortunate that in the prosecution of this work the society was dependent upon the financial aid derived from the fines imposed, and he would recommend that a committee be appointed to investigate the matter and report concerning the possibility of doing away with this objectionable feature.

The speaker said that in the past two years there had been some notable improvements in the conduct of the two departments of the city government most closely allied to the medical profession, *i.e.* the Department of Public Charities and the Department of Health. It was difficult to believe that the present Commissioner of Charities, Mr. Homer Folks, could have accomplished so much in the short space of twenty-two months. Similarly the present Health Commissioner, Dr. Ernest Lederle, had brought his department to the highest state of efficiency in its history. A distinct advance would be made in the maintenance of good city government if our citizens could be made to appreciate fully the fact that the death rate rises or falls in direct proportion with the efficiency of the street cleaning, charities and health departments.

The society began the new year with a membership of more than 1,700, making it by far the largest medical society in the City of New York. It was his purpose as the presiding officer to spare no effort to maintain a vigorous administration of its affairs, both in things scientific and secular.

**The Tendency to Tuberculosis.**—Dr. JOHN B. HUBER read this paper. He said that many persons at the present day were of the opinion that tubercle bacilli gained entrance frequently through the alimentary canal, the course to the lungs being through the lacteals, the thoracic duct, the vena cava, the right heart, and the pulmonary circulation. If this theory were true it was certainly of transcendent importance that food and the secretions from the nasopharynx should be bacillus-free. Under the head of environment, perhaps, one of the most potent causes of tuberculosis was alcoholism, with its attendant evils.

**A Brief Description of the State Hospital for the Treatment of Incipient Tuberculosis.**—Mr. HOWARD TOWNSEND, Chairman of the Board of Directors, said that the trustees had had to contend with many things, and although there had been so much delay he felt that they were entitled to at least a little credit. To Dr. E. L. Trudeau was due the credit of selecting the site at Raybrook. It was located four miles and a half southeast of Saranac Lake, on the line of the railroad going from Saranac Lake to Lake Placid. The site comprised nearly a square mile of ground, on which was woodland, meadow, and pasture. The hospital itself was built on the southern slope of a hill, entirely protected from the west and southwest winter winds, and faced the southeast. The hospital was intended to accommodate only one hundred patients and only those suffering from incipient pulmonary tuberculosis. He could not say when the hospital would be opened, but he hoped some patients would be there by next March, and that the hospital would be in full working order by next August.

**Recent Care of Tuberculous Patients by the Department of Public Charities.**—Mr. HOMER FOLKS, Commissioner of Public Charities, reviewed what had recently been accomplished by his department in the care of cases of tuberculosis, illustrating his remarks by numerous photographs and lantern slides of the various buildings and tent cottages. He said that 142 patients had been accommodated in twelve tent cottages, built after the plan of Dr. Holmes. A large number of tuberculous persons were cared for in an old building that had been vacated by the Manhattan State Hospital for the Insane. In this building all the sickest patients, *i.e.* those confined to bed, were placed on the top floor, while the others occupied the two lower floors. In a few days they would open probably the first house intended wholly for dining purposes, and designed by a woman. It would seat 350 persons, and the food was to be served hot while these persons were seated at the tables. At first, a considerable quantity of cod-liver oil and liquors had been given the tuberculous patients, but last summer these supplies were largely discontinued, yet the results had been in no way inferior to those previously obtained. After the tubercolosis infirmary had been in operation for three or four months, a graduate of Princeton University was made superintendent of the institution, and was instructed to become personally acquainted with every patient, explain the nature and objects of the institution, and personally ascertain the reason for each patient's discharge. He was also given charge of the social features of the institution, and of such employment as might seem desirable. This gentleman's work seemed, to the speaker, exceedingly important. The institution was not, of course, looked upon as a model one, and he did not think it should be further enlarged. It now rested with the Board of Health to select a proper site for the out-of-town tuberculosis sanatorium for the city. It was difficult to state just what had been accomplished with the tuberculous patients at this infirmary on Blackwell's Island, but he would say that, in the main, those who were not evidently in the last stages of the disease at the time of their admission, had rather uniformly gained in weight and strength for a certain period of time. A certain number of them, at the present time about fifty, were pronounced by the physician to be practically cured. Quite a number of these had been placed upon the payroll as employees of the institution.

**Recent Measures Adopted by the Health Department for the Care of Tuberculous Patients.**—Dr. JOHN S. BILLINGS spoke briefly on this topic. He said that the registration of tuberculosis cases was secured by notification from institutions, by notification from physicians, and by sputum examinations. He was sorry to say that even now the smallest number of cases reported was by physicians, and out of 8,500 sputum examinations, only 3,200 cases were reported. They were preparing two indexes, one of all of the new cases of tuberculosis and another of all the consumptive poor under the observation of the department. Fully 40 per cent. of the cases reported by the institutions could not be found, largely because of wrong addresses having been given. The statistics of the department showed that there had been recently practically no fatal cases reported as dying of other diseases in order to conceal the fact that the cause of death was tuberculosis. There was a corps of inspectors, and also a corps of nurses, the latter following up the cases reported by the inspectors. It was the intention of the department to open a dispensary on the first of next January. The chief object of this dispensary was to strengthen the control of the department over the consumptive poor.

**Brief Description of the Stony Wold Sanatorium.**—Dr. JAMES E. NEWCOMB presented this description. He said that this sanatorium was the work of women for women, and was intended for incipient cases of tuberculosis, occurring in working women and children, including boys up to the age of twelve years. After due deliberaton, the present site in the northern Adirondacks, eight miles beyond Paul Smith's station, was selected. It was on the line of the New York Central Railroad, 379 miles from New York City. At present this site embraced two thousand acres of land and water, and was at an altitude of 1,730 feet. The main lake comprised about 350 acres. Most of the land was heavily wooded, and the soil was admirably adapted for drainage. The supply of water was from a lake, about one-third of a mile away. The grounds had not come into the possession of the trustees until December, 1901, and the formal opening exercises were held last August. The architects were those who planned the Adirondack Cottage Sanitarium. There were, at present, accommodations for about sixty patients, including sixteen children, although there were only twenty-five or thirty patients in the institution at present. Eventually accommodations would be provided for 150 patients. There were no free beds now, each patient being charged one dollar a day in advance, with no extras, except a charge of twenty-five cents per week for laundry. Each patient was received on probation for one month.

**Comparison of American and Foreign Methods of Sanatorium Treatment of Tuberculosis.**—Dr. HENRY P. LOOMIS discussed this subject briefly, illustrating his remarks by lantern slides. He said that the sanatorium treatment of tuberculosis had been in existence abroad for about forty years, and had reached its highest development in Germany during the past twenty years. In this country such treatment had only been in vogue, to any extent, for the past eight years. All sanatorium experience demonstrated beyond any doubt that tuberculosis was a very curable disease. The attention to slight details in each individual case was, in the opinion of the speaker, what accounted very largely for the great success of the sanatorium treatment. The sanatoriums abroad were constructed on the pavilion plan; in this country, they were, for the most part, on the cottage plan. This idea of having only a very few patients together under one roof was distinctively American. In Germany, either owing to the long familiarity with sanatorium treatment, or to the different national temperament, the people, when attacked by consumption, immediately went to a sanatorium. Again, the discipline, of the sanatorium abroad, particularly in Germany, was something which could not possibly be enforced in this country. The medical profession abroad did not consider altitude as of so much importance as did the physicians in this country, and, hence, many of their institutions were located in low altitudes; nevertheless, the two most successful sanatoriums abroad were situated at 1,300 and 1,800 feet respectively. It was worthy of note that in the foreign sanatoriums, creosote was not used, and it was believed that it was rather prejudicial. On the other hand, they made use of what was very seldom employed here, *i.e.* hydrotherapy.

---

**Feeling for the Cord Immediately After the Birth of the Head.**—Schultze wishes to abolish the universal custom of examining the child's head with the finger immediately after the birth of the head to determine whether the cord surrounds it or not. There is no doubt of the risk to the child when this condition is present, but the danger lies chiefly in compression of the cord between the symphysis and neck during the latter part of the descent, as soon as the head is born this danger ceases, while shortness of the cord sufficient to cause dystocia or premature separation of the placenta gives symptoms so pronounced as to make the diagnosis certain without digital examination. The great danger consists in having a band, often of questionable sterility, introduced into the freshly lacerated genital passages of every parturient woman, a procedure which, granted its superfluousness, is contrary to all the tenets of modern obstetrics.—*Centralblatt für Gynäkologie.*

**Contagious Diseases—Weekly Statement.**—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending December 5, 1903.:

| | Cases. | Deaths. |
|---|---|---|
| Measles | 326 | 6 |
| Diphtheria and croup | 408 | 68 |
| Scarlet fever | 211 | 19 |
| Smallpox | 1 | 1 |
| Varicella | 104 | ... |
| Tuberculosis | 306 | 163 |
| Typhoid fever | 68 | 12 |
| Cerebrospinal meningitis | ... | 3 |

**How a Pullman Car Is Cleaned.**—The management of the Pullman company, in controversion of the recent criticisms of the sanitary condition of their cars has sent out this statement of just what the process of cleaning a Pullman car is: As soon as a Pullman car arrives at its destination it is entirely stripped, the carpets are beaten and aired and the interior of the car is thoroughly scrubbed with soap and water. The blankets are taken out of the car and are thoroughly blown out with compressed air at a ninety-pound pressure. It is impracticable to wash them after every trip, but they go to the laundry several times a year, which is oftener than is the case with hotel blankets. All linen is renewed each trip. Every case of sickness in a car, however trivial, is followed by the antiseptic cleansing of the section occupied by the sick person, and the entire car is sprayed with formaldehyde. As a further sanitary precaution, in the newer cars of the company, purely decorative draperies are being omitted, and the necessary ones, such as berth curtains, are being made of a lighter material which does not hold dust or odors.—*The Sun.*

**A Golden Opportunity.**—It has been my experience that the greatest movements to help the consumptive poor have always originated through the activity of some family physician who could interest his wealthy friends or patients, or even the municipality in the cause. Therefore, should these lines be read by anyone of my colleagues who is in the position to help, I beg him to exert his influence as much as he can on behalf of the poor consumptive in our tenement districts.—S. O. KNOPF.

**Massage by the Blind.**—Among the Japanese, from whom we have yet much to learn, massage is generally recognized as the work of the blind The sightless Japanese operators are masters in their useful craft. The blind are usually endowed, by way of compensation for their loss of sight, with a sense of touch exceptionally acute, so that here is a field in which they may surpass their seeing fellows. Massage is chiefly dependent for its success upon the delicacy of its application, which depends in its turn upon the nicety of the operator's sense of touch.—*Medical Magasine.*

**Increased Longevity.**—The International Congress of Insurance Actuaries held its session recently in New York City. A prominent feature of the discussion was the admitted fact that people are longer lived now than formerly. This was attributed to the growth of hospitals, the advance in medicine and surgery and the more enlightened care of the poor and suffering, especially of the children. John K. Gore of Newark, N. J., presented statistics showing that during the last five years of the century there had been a very perceptible decrease in the mortality rate. From 1870 to 1874, the period including the fatal smallpox epidemic of 1872, there was an increase in the death rate of every age group but one. From 1880 to 1884 the rate was relatively high, owing to the great prevalence and wide distribution of diphtheria scarlet fever, and measles. The influenza epidemic of 1891 caused an augmented death rate from 1890 to 1894. As to causes, it was stated that there had been a remarkable decrease in the death rate from phthisis, and a slight decrease from typhoid fever in the northern countries.

**The Use of Adrenalin in Anæsthetic Injections.**—Braun considers adrenalin of great value as an addition to local anæsthetic mixtures, but finds caution necessary in regard to two points, viz.. toxic effects and secondary hemorrhage. Eight centigrams of cocaine, together with eight drops of one to one-thousand adrenalin chloride solution, have caused death, and even three drops are reported by Enderlew to have produced uniformly untoward symptoms. The author has often exceeded this dosage, however, without bad effects. The desired action of the drug, *i.e.* intensification of the anæsthetic properties of cocaine and eucaine, can be produced to the full by amounts so minute as to be absolutely harmless, while larger quantities are undesirable, through their tendency to permit secondary hemorrhage. Contrary to general belief, adrenalin does not cause a secondary relaxation of the vessel walls leading to oozing, but owing to its intense styptic action in larger quantities, even arteries, are kept from bleeding, and hence allowed to go without ligature. When the effect of the drug wears off the open vessels bleed, not because of any fault of the adrenalin, but because they were not secured. In minute amounts the anæsthesia is greatly enhanced, parenchymatous oozing entirely checked, but all vessels of any importance still bleed and may be ligated as usual. The solution used by the author for Schleich's infiltrations contains one-tenth per cent. cocaine with two to five drops of adrenalin chloride one to one-thousand to each one hundred cubic centimeters.—*Centralblatt für Chirurgie.*

**Health Report.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended December 5, 1903:

### LEPROSY IN HAWAII.

By JAMES T. WAYSON, M.D.,
HONOLULU, T. H.

LEPROSY is defined as an endemic, chronic, constitutional disease analogous to syphilis, caused by the Bacillus lepræ, and varying in its morbid manifestations, depending upon the tissues of the body affected, such as the skin, the nerves, the mucous surfaces, the lymphatic ganglia, and certain viscera.

It occurs in three forms, the tuberculated, non-tuberculated or anæsthetic, and the mixed tuberculated.

"The microscope is the supreme agent of the final diagnosis of leprosy. No patient should be committed to a segregated colony without a bacteriological demonstration of the disease. Of clinical symptoms, maculæ, chiefly leucodermic spots, are found in 89 per cent. of all cases. The lepra nodule, found in 74 per cent., is the one chief distinguishing lesion of skin leprosy. Thinning or complete loss of eyebrows and lashes is present in 63 per cent. Atrophic changes in hands and forearms with retraction and contraction of fingers and enlarged ulnar nerve in 32 per cent., a leading feature of nerve leprosy. The plantar ulcer found in 26 per cent., usually on the ball of the foot. Absorption of phalanges in 16 per cent., with occasional spontaneous amputation. Elephantiasis of hands and feet in 16 per cent. Facial paralysis in 11 per cent. The entire body should be carefully tested for anæsthetic areas. Some of the above symptoms can be found in some slight degree at least in every leprous subject" (J. T. McDonald).

At the present time it is firmly believed that the Bacillus lepræ, discovered by Hansen, is the cause of leprosy, but its method of entering the human body is absolutely unknown, whether by the skin, with or without abrasions; the mucous membranes; inoculations by insects; inhalations; or by articles of diet, such as salted or dried fish—the latter a theory of Jonathan Hutchinson of London, who believes the lepra bacilli are in such food. However, it is well known in Hawaii that people become leprous who have never made salted or dried fish a part of their diet.

Personally, I believe that a syphilized people are more susceptible to the disease than even the offspring of lepers; also, that there is but a slight predisposition among the children of leprous parents, and that the disease is in no way hereditary. Touching upon the point of the heredity of the disease, a striking peculiarity is to be noted, and that is, that while brothers, sisters, and cousins may be lepers their parents are aliens to the disease.

According to the latest authorities it is unknown whether the Bacillus lepræ has spores, but I believe it has, and that it is by the spores the disease is spread. The spores are thrown off the body of a leper and become lodged either in the integument or mucous membranes of a predisposed healthy person, where they remain inactive for many years, or become very active within a short time, developing into full-grown bacilli, and soon manifesting their presence by the usual lesions of leprosy.

Father Damien de Veuster said that when near lepers, as at confession, or in their cabins before coming to the Leper Settlement, he felt on each occasion a peculiar sensation in the face, a sort of itching or burning, and that he felt the same here at the Settlement, during the first two or three years.

The first lesions of leprosy are surely local, as there is undoubted evidence of aborted cases, especially in the purely anæsthetic form. The activity of the spores is due to their passage through the air before entering the human body (otherwise direct inoculation would be possible—an experiment which has often been tried, but has never been successful), and is also dependent upon the predisposition of the human body—which is probably caused by certain foods, syphilis, and climate, which so modify the tissues that the otherwise healthy person becomes a suitable soil for the growth of the bacillus.

I believe the length of life of the lepra bacilli is so short that it accounts for the inability of experimenters to cultivate it, and that the danger of infection is wholly due to the activity of the spores. Also, that it will be necessary before a cure is obtained, to find some drug that will act solely upon the spores (having a selective action upon the skin and mucous membranes of the diseased person), destroy them, and at the same time overcome the condition of the system upon which the spores seem to thrive. If a cure is obtained it will certainly stop the spread of the disease by eradicating the source of infection.

No specific remedy is known. General tonic treatment and hot baths with hygienic surroundings aid in checking the disease.

The Kausatsu Springs of Japan are reported to check materially the advance of the disease, and I have received personal letters from lepers who firmly believe they have been cured by the baths. It is a very severe treatment, but certainly very efficacious.

*Leprosy in Hawaii.*—The first attempt by the kingdom of Hawaii to check the disease of leprosy or to cure or alleviate the sufferers was made in 1865, when an act, entitled, "An Act to Prevent the Spread of Leprosy," was officially passed.

The native Hawaiians believed the disease to have been brought among them by the Chinese, so named it "mai pake" (Chinese disease), but it is well proven that the disease was among the natives before any Chinese had visited or lived in the Islands. In all probability it came from the South Sea Islands, as the disease was endemic there and the people of those Islands frequently visited Hawaii.

A hospital established for the examination and

treatment of persons affected with leprosy, was opened on the 13th of November, 1865, and has been in existence ever since. It is now known as the

Anæsthetic leprosy, showing the leper claw and palmar ulcers.

Kalihi Detention Hospital. Persons supposed to be affected are sent to the Kalihi Hospital, where

Macular eruption in early stage of anæsthetic leprosy.

they are thoroughly examined by a commission of physicians and a bacteriologist.

At the present time the lepra bacillus must be demonstrated before a leper is sent to the Settlement at Molokai. Previous to 1897 no bacteriological examination was made. Any person showing clinical symptoms sufficient to warrant the commission to keep them under observation, is kept at

Anæsthetic leprosy, showing muscular atrophy and mutilations of the hands and feet.

Macular lesions of anæsthetic leprosy showing the gyrate patches with elevated margins.

Kalihi or required to report at short intervals for further examination until the presence of the lepra bacillus is firmly established.

At Kalihi there is also a very creditable home, called the Kapiolani Home, conducted by the Franciscan Sisters. Here all the girls born of leprous parents at Molokai find a good home with the Sisters.

The Leper Settlement is situated on the Island of Molokai, one of the principal islands of the Hawaiian group. The peninsula upon which the settlement is located has an area of eight square miles, and is on the northern coast of the island; it is commonly known as Kalaupapa, named after the high precipice separating the peninsula from the rest of the island. The pali is about 2,000 feet in height, and is a natural barrier against escape, by land, of any of the inmates of the Settlement. A zigzag road has been cut down this nearly perpendicular pali, which would certainly take an old and accustomed mountaineer nearly one hour to descend.

There are two separate residence portions on the peninsula, known as Kalawao and Kalaupapa, giving an appearance of two small villages, as there are churches, stores, houses and streets, which go to make up a country-town of equal population. A jail is also in evidence, as it is at times necessary to punish the unruly there as well as in other communities, therefore you will find a resident magistrate, and one or more police.

The Settlement is governed entirely by the Board of Health; the Board having sole control of the people, whether lepers or non-lepers, at the Settlement. There is the Superintendent of the Settlement, an employee of the Board, who makes regular trips back and forth from the Settlement—who also does the buying of all necessary clothing and provisions (issued by the Government), attends to all disputes between the lepers where law is not called in action, and makes regular weekly reports to the Board of Health—in fact, the Superintendent has general supervision over the entire workings of the Settlement, under the direction and approval of the Board of Health. An assistant superintendent, usually a leper, is located at the Settlement.

A skilled physician and surgeon is a resident at the Settlement, and he has but little spare time, as the ailments of the lepers are many. His position is a most difficult one to hold, as the Hawaiians are very apt to have their own medicinemen attend them at the same time the resident physician is attempting to aid them. They will accept his remedies, but most likely throw them away, preferring the crude method of their kahuna or doctor.

There are two fine institutions, the Baldwin Home for boys (so called after the donor), and the Bishop Home for girls (also named after the donor), which, carried on in an ideal way, aid very materially in taking care of the young children.

There are Catholic and Protestant churches, also a Y. M. C. A. branch, having cheerful and suitable quarters.

There is a brass band, which very often gives public concerts for the amusement of the lepers, and every holiday is carried out in the usual manner of the Hawaiians, such as with a "luau" or feast, horse racing, and games.

The number of lepers admitted to the Settlement, from January, 1866, to December 31, 1875, the first ten years of segregation, was 1,587. The number admitted during the last ten years, ending June 30, 1903, was 888.

The largest number admitted in any one year was in 1873, when 487 were sent there; the smallest number was in 1886, there being but 43 admitted. The largest number there in any one year was 1,213, in the year 1890, and the smallest number after the first ten years of segregation was 590, in the year 1886.

At the end of June, 1903, there were 540 males, and 348 females at the Settlement, 796 being Hawaiian, 6 American, 2 English, 7 German, 49 Chinese and Japanese, and 28 of other nationality.

The present estimated population of Hawaii, including the lepers at Molokai, is 150,000, therefore the number of known lepers to each hundred of the population is one. Not knowing the length of the stage of incubation, it is extremely hard to estimate the number of lepers at large that are at the present time a source of infection to healthy people, but taking into consideration the number yearly admitted to the Settlement, and the advance condition of the disease of those taken, it is quite evident that from three to four hundred are at large. They are not a source of infection to the average inhabitant, because as soon as they realize they have the disease, they keep very close at home, or take up their abode in the high valleys and hills away from any chance of a passing stranger or police agent seeing them. Their relatives and friends supply them with food and clothing, and warn them of danger, therefore it is a very difficult matter to apprehend them.

It cost the territory of Hawaii about $116,400 per year to care for the lepers, $30,400 being paid for salaries and the balance for expenses at Kalihi and the Settlement, $86,000.

The care of lepers will soon become a national question, as it is a national calamity rather than a purely local issue. The Federal Government, with its Bureau of Public Health and Marine Hospital Service, having at its disposal well qualified and able medical men to attend to the physical wants of the lepers, and equally as well trained men capable of superintending such a Settlement, is surely better equipped to handle such serious conditions than even the Government of Hawaii, although great credit must be given this Government for the way it has taken care of its own afflicted.

During the time the Sub-Committee on Pacific Islands and Porto Rico was in Hawaii in 1902, the question of the Federal care of lepers came before it, and the greatest objections put forth by many people here, were:

(1) That the "dumping" of the mainland lepers in Molokai would be a source of discontent and at times riot at the Settlement, but here, it would seem, the fact was overlooked that the mainland lepers are equally as unfortunate and just as law-abiding as the present inmates of the Settlement, and as capable of affiliating with the Hawaiian peopl ethere, as the people affiliate with them outside the Settlement.

(2) That the Federal Government would not be as careful and considerate of their modes of living and diet, Here, again, the fact is overlooked that the Federal Government is just as humane as any local or foreign government would be in the care of their afflicted wards, and that it would as gladly furnish the Hawaiian leper his poi and fish as the present Government of the Territory of Hawaii is doing at the present time.

(3) The most serious objection would come from the Hawaiian lepers at the Settlement, supported by many of the former men who have had their care, and that is the fear that the Federal Government will segregate the sexes. At the present time

and ever since the Settlement was established the lepers have been allowed to marry, but few children have been born in consequence, as it is well known that lepers bear but few children, the male frequently becomes impotent and the female sterile, which greatly lessens the danger of bringing children into the world. If the woman becomes pregnant, it is

Perforating ulcers of anæsthetic leprosy.

no uncommon thing for her to abort as frequently as in syphilis.

Therefore, taking into consideration the fact of there being between three and four hundred known lepers on the mainland and several thousand in Guam and the Philippines, with the known conditions in

Lesions of tubercular leprosy.

Hawaii, the Federal Government will sometime in the near future awaken to the necessity, as did the Hawaiian Government in 1865, that something must be done with the lepers of our country and her colonies.

It would be somewhat of a hard task, but with the Government's usual good methods and foresight, the vexed question of segregation of lepers, even to the segregation of the sexes, and their care and treat-

Early stage of tubercular leprosy.

ment, would be accomplished for the good of the unfortunate lepers, and protection of the people from future danger of contagion.

The illustrations are from photographs of typical

Leonine facies of tubercular leprosy.

cases of leprosy as we see them at the examinations in the Leper Receiving Station. They show how far advanced the disease usually is before the sufferers are sent to Molokai. and emphasize the need of earlier segregation.

# THE DIAGNOSIS AND TREATMENT OF INTUSSUSCEPTION, WITH A REPORT OF FOUR CASES.*

By HENRY ROTH, M.D.,
NEW YORK.
ASSISTANT ATTENDING SURGEON, LEBANON HOSPITAL, NEW YORK.

Acute intussusception forms about one-third of all varieties of acute intestinal obstruction. In children and infants it is the most common variety of obstruction. More than one-half of the cases occur in children, and fully one-half of these are under twelve months of age. The disease may be acute, subacute, or chronic. Four cases of acute intussusception came under the writer's observation in a comparatively short space of time. One case occurred in an adult and three in infants, less than one year old. All of these patients were admitted to the service of Dr. Parker Syms, at the Lebanon Hospital, and of these, two were operated upon by the writer.

The histories are as follows:

Case I.—W. M. G., age forty years, single, admitted to Lebanon Hospital February 6, 1903. Good family history; venereal history is negative. Eighteen years ago the patient had a cough and expectorated blood for two years. After that he was perfectly well up to six years ago, when he had an attack of pain and vomiting like the present one. He remained in bed for a few days and recovered without medical aid. On February 5 patient worked the entire day throwing stones out of a wagon. At 5 P.M. he stopped work and went home; while partaking of his dinner, consisting of meat and potatoes, he felt a sudden pain, dull and rolling in character, most of the pain being in the right iliac region. He had to lean against the chair and the pain became gradually worse, which compelled him to take to his bed. He could not sleep on account of the pain, and of the incessant vomiting, which began soon after the initial attack of pain. Vomiting continued all night and the next day. Bowels moved several times on the following day; he could not retain even a drop of water. During the night he was seen by his physician, who sent him to the hospital, with a diagnosis of appendicitis. When he reached the hospital his temperature was normal, pulse 88, respiration 24. On examination, a distinct mass was palpable in the right iliac region. There was rigidity and considerable tenderness over the right side of the abdomen. Abdomen somewhat distended. After admission to the hospital, bowels moved freely after a soap-suds enema. On February 7, 1903, forty hours after the first symptom appeared, he was operated upon by the writer. Under ether anæsthesia, the abdomen was opened through a Kammerer incision. On opening the peritoneal cavity, a quantity of serous fluid escaped. The appendix was found normal. On further examination a movable mass was felt, which proved to be the cæcum and ascending colon, with the ileum invaginated. An ileocolic intussusception was demonstrated, and an attempt made to reduce it. This was impossible and resection was decided upon. The ileum was divided about two inches above the neck of the intussusception, and an incision around the ileocæcal valve allowed removal of the entire mass. The ileum and cæcum were united with the aid of a Murphy button, reinforced by a row of Lembert sutures. The abdominal wound was closed, down to its lowest portion, which was drained with iodoform gauze. The intussuscepted ileum, which was constricted by the ileocæcal valve, was considerably swollen and discolored a dark brown. Attempts to unfold the mass, even after its resection, were difficult. About thirty-two inches of ileum were resected.

After the operation the patient reacted well, but complained of considerable pain. He was given nutritive enemata, which he retained. The bowels moved on the third day after the operation. On the fifth day fæces appeared in the wound. This caused considerable excoriation of the skin, and required frequent changes of dressings. The fecal fistula contracted down to a small caliber, and on March 20, 1903, an attempt was made to close it. Under ether anæsthesia, the fistula was dissected out and the gut closed with silk Lembert sutures. The patient's condition was not very good after this operation; his pulse was 120, of poor quality; vomiting was incessant; the bowels, however, moved the day after operation, and the nutritive enemata were retained. On the fourth day leakage of fæces was noticed, which continued, but the general condition improved rapidly. The fistula became smaller, and on April 29, 1903, the writer operated through an incision near the median line. With the aid of a Murphy button, lateral anastomosis was performed between the small intestine and the ascending colon. This was done to short-circuit the fecal current. The bowels moved three days after the operation, and the button passed on the ninth day. There was some leakage from the original fistula.

At the time of writing, the patient is out of bed, has some leakage, but his bowels move more freely than at any time, and his local and general conditions are improving rapidly.

Case II.—Gertrude M., four and a half months old. Native of the United States, was admitted to Lebanon Hospital February 21, 1903. An infant brother of the patient died from acute intussusception nine years ago. On February 19 the patient suddenly started to cry, and continued to do so, apparently having a great deal of pain; vomiting set in and continued. The child's bowels did not move, but it passed blood and mucus, and strained constantly. The mother, learning from past experience, recognized the acute nature of the condition, and informed the family physician. Castor-oil and calomel were prescribed, but without any result. The child became more and more fretful and exhausted. On the 21st of February the mother was advised to take the child to the hospital for operation. On examination a tumor could be seen in the region of the sigmoid flexure. On palpation a long tumor was felt extending from the epigastrium down to the region of the sigmoid and hypogastrium; the mass was freely movable. Rectal examination revealed a tumor in the lumen of the rectum, about one and one-half inches from the anus. On withdrawing the finger it was found stained with blood. Otherwise the abdomen was not distended. The child was well-nourished, was listless, and took no notice of its surroundings; pulse 146, hardly perceptible at the wrist. Temperature subnormal; cold extremities and marked cyanosis. At the most urgent solicitation of the mother, laparotomy was performed. An incision was made through the left rectus muscle. The neck of the intussusception was found in the transverse colon. The tumor was irreducible, and on account of the desperate condition of the child, an artificial anus was made, and the rest of the wound closed. The child reacted to some extent, but only temporarily, and died six hours later.

*Read before the Medical Society of the Borough of The Bronx.

Case III.—Thomas S., age four and one-half months, native of United States, was admitted to Lebanon Hospital February 26, 1903. The patient was the only child in the family, and had had no previous illness. The child was taken sick suddenly on Monday, February 23, 1903, at 6 A.M. Began to cry as if it had colic. At noon of the same day vomited for the first time. Rhubarb was given, and in the evening some castor oil. That same evening the child had blood and mucus discharges from the rectum; otherwise, was constipated. The vomiting and the bloody discharge from the rectum continued. The child was getting progressively worse, and was brought to the hospital on Thursday, February 26, 1903, in a state of collapse, with an imperceptible pulse. On examination, four days after the onset of the disease, the child was found to be unusually well developed. The abdomen was slightly distented, and no distinct mass could be felt. Rectal examination was negative. The child was apathetic, took no notice of its surroundings, and only cried feebly when the abdomen was palpated. Temperature subnormal, and pulse imperceptible at the wrist; respirations very shallow; cold and cyanotic extremities; vomiting stercoraceous material, and seems to be moribund. At the most urgent request, on the part of the mother and family physician, an operation was attempted as a desperate last resort, but could not be undertaken on account of the rapid failure of all the vital functions. The child died within a short time after admission to the hospital.

At the autopsy an ileocæcal intussusception was found, and resected.

The intussusception is about three and one-half inches in length, the cæcum being intussuscepted. Only part of the appendix is seen protruding from the unsheathed bowel. The intussuscepted bowel is much swollen and very dark.

Case IV.—Gertrude E. S., six months of age, admitted to Lebanon Hospital, April 5, 1903. The patient is an only child, and had never been sick until the present time. On Wednesday, April 1, at 6 P.M., the child was suddenly taken ill with a severe crying spell, followed soon after by vomiting of a whitish material, resembling curdled milk. About half an hour later the bowels moved, a brownish fluid being passed. A second movement occurred about fifteen minutes later, the character of the stool being similar to the first. One hour later the bowels moved for the third time, the movement this time being distinctly bloody; blood was repeatedly passed, this continuing through the following day, and all this time being accompanied by vomiting. After Thursday night the stools were very slight in quantity, and of a dark, brownish-red color. A physician was called in on Wednesday, about an hour after the beginning of the disease. He prescribed some powders which were vomited. The next morning he called again and gave a liquid preparation. This call was repeated in the afternoon. On Friday, the third day of the disease, an enema was ordered, which was expelled immediately after admission. On Saturday, at 4 P.M., a consultation was held, and an enema was given with the aid of the fountain syringe; the result being negative, the parents were advised to take the child to the hospital for operation. The patient was admitted four days after the onset of the disease.

On examination the child presented the appearance of one very sick, was apathetic, eyes sunken, and did not cry. There was complete muscular relaxation; constant vomiting of stercoraceous material. The abdomen distended, and a mass was felt on the left side, which seemed tender. Rectal examination revealed apex of intussusception, one and one-half inches from the anus. There was a constant discharge from the rectum, of a material which looked like currant jelly. Radial pulse imperceptible, temperature 104°, respiration shallow; extremities cyanosed. The child being moribund, and it being almost four days since the intussusception occurred, operation was not deemed advisable, or was it considered that it would be of any possible benefit. The child died five hours after admission, the vomiting and bloody mucus discharge from the rectum continuing to the last.

Autopsy revealed an ileocæcal intussusception, which was removed and found to be about eight inches in length.

Observation of these cases impressed the writer with the fact that this disease is frequently overlooked, or else diagnosed too late in its course. Furthermore, it seems that the importance of the surgical treatment of intussusception is not fully recognized, and that mechanical treatment is given too long a trial. The experience of the writer leads him to believe that in many cases surgical treatment is sought only as a last resort. A study of the above histories shows that intussusception in children is attended by a characteristic chain of symptoms which should lead to an early diagnosis. The diagnosis once made, should be followed by early treatment, which, in every instance, should be surgical from the very beginning. Observation of these cases in so short a time, led the writer to a study of this disease, and a review of its recent literature.

The two most exhaustive essays on the subject, in recent American literature, are those of Wiggin, in 1896, and Gibson, in 1897. Wiggin[1] reports two personal cases, and his essay is based on a study of 103 cases treated either by intestinal distention or laparotomy. In his study he observed that while English surgeons paid considerable attention to the subject, and many cases have been recorded in English literature, American journals contain a comparatively small number of scanty reports. His cases are gathered from the English and American literature, since the beginning of the nineteenth century. Of the 103 cases collected, nearly 50 occurred at the fourth, fifth, and sixth months, in almost equal proportion. Of the 39 cases treated only by means of inflation or enemata, or both, 16, or 41 per cent., recovered, and 23, or 59 per cent., died. He found 72 cases in which distention was tried, but some of these cases were subsequently operated upon. In 54, or 75 per cent. of these cases, reduction failed, and had none of them been operated upon subsequently, the mortality of the treatment by injection would be represented by 75 per cent. Sixty-four cases were treated by laparotomy; 21, or 32.8 per cent., recovered, and 43, or 67.2 per cent., terminated in death. Excluding the operations done previous to 1889 and those of incomplete operation, there are left 18, of which 14 recovered and 4 died, showing the still lower mortality of 22.2 per cent.

Gibson,[2] in 1897, read an exhaustive paper on the mortality and treatment of acute intussusception, based on a study of 239 tabulated operative cases. His deductions are based on the largest recorded number of cases, and hence, their great value. Gibson obtained most of his cases from the tables of Braun,[3] Barker,[4] Rydygier,[5] Wiggin,[1] Braun collected all the reported cases up to 1895. Some of the cases collected by this writer do not belong to the purely acute form, and were not included in Gibson's statistics. He found the presence of a bloody discharge from the rectum the

most constant symptom, and considers that when present in a young child, accompanied by the sudden onset of abdominal symptoms, it is pathognomonic. He notes fecal vomiting as infrequent, and calls attention to the fact that in general, palpation of the abdomen yields more definite data than any other form of acute intestinal obstruction. Only the cases since 1887 have been utilized for deductions concerning operations. The mortality in 149 cases was 53 per cent. The first two days show the lowest mortality, while with each succeeding day it increases steadily, and is greater than the average mortality. Of 99 cases, in which reduction was possible during the operation, 38 died, a mortality of 38 per cent., while of the 50 cases in which the reduction could not be performed, the mortality was 82 per cent., or more than double. The proportion of non-reducible cases is shown to increase steadily after the first day. In the cases in which an artificial anus had to be made, the mortality rate was 86 per cent., and in cases requiring resection it was 79 per cent., or 82 per cent. for both, that practically being the mortality rate for irreducible cases. The ileocolic variety gave a mortality of 72 per cent., the enteric, 64 per cent., the ileocæcal, 58 per cent., and the colonic, 50 per cent. Gibson calls attention to the fact that the mortality is due not so much to the tender age of the patient, as to the condition itself. He contrasts the mortality of 53 per cent. from acute intussusception, with the mortality of 42.1 per cent. from other forms of acute intestinal obstruction, and is strongly impressed with the fact that our method of dealing with intussusception must be improved upon. To reduce the high mortality earlier operation is urged, so that the cases might be operated upon while the intussusception is still reducible. Gibson considers the treatment by inflation or injection as uncertain, deceiving and dangerous, and believes that it frequently delays the favorable moment for operation. He would limit its application to one attempt under anæsthesia, in the first twenty-four hours, the patient being prepared for immediate operation should reduction be impossible. Should there be uncertainty regarding the successful reduction, laparotomy is urged. He then describes the details of the treatment by laparotomy and advises immediate incision, under chloroform and ether anæsthesia. He cautions against pulling on the intussusceptum. In the irreducible forms he finds the following methods to choose from: artificial anus, enteroanastomosis, partial resection and typical resection. The first of these methods should be resorted to only in the most desperate cases, in which the patient's condition will not permit any other measure. In gangrenous intussusceptions, resection with immediate union of the divided intestine, or resection with utilization of the divided ends for a temporary artificial anus, is recommended. Maunsell's method is commended for enterorrhaphy.

In searching the literature since 1897, the date of Gibson's paper, it will be observed that most of the cases are recorded by English surgeons, who seem to pay more attention to the subject than the American, German, or French. The greatest number of cases are recorded from England, Australia, and Canada. The same observation was made by Wiggin, dealing with the literature prior to 1896.

In 1898 Edward Martin,[7] in response to 800 communications, most of which were answered, could obtain the histories of only 54 cases occurring in the practice of various surgeons. Only 15 of these were operated upon; 2 recovered and 13 died, giving a mortality of 86 per cent. This he attributes to operations which were delayed until the time when there was no hope from any other method of treatment.

Intussusception was the principal subject for discussion in the Section on Pediatrics of the British Medical Association, at its meeting in 1901. The papers read dealt with large numbers of cases, and the deductions derived from their study are of the greatest value.

Pitts[8] based his paper on a study of 115 cases occurring at St. Thomas' Hospital from 1875 until 1900. There were 105 children under 12, of which number 36 were cured, 13 after injection of water or air, and 23, or almost twice as many, after laparotomy. Since 1897, with the exception of one seven months' old baby, all cases were treated by laparotomy. The author is in favor of immediate operation, and condemns attempts at reduction by injections or inflation.

D'Arcy Power[9] studied the cases which occurred at St. Bartholomew's Hospital and the Victoria Hospital for children from 1860 to 1890. There were observed 113 cases; 66 died and 47 recovered.

William McAdam Eccles[10] studied 96 cases which were admitted to St. Bartholomew's Hospital; of these, 63, or over 65 per cent. were in children under one year. The total mortality was 55.2 per cent. Thirty-two cases were admitted on the first day. Of these, 19 got well and 13 died. On the second day 16 were admitted; of these, 10 recovered and 6 died. Between the third and seventh day 36 were admitted; 17 recovered and 29 died, showing the increase in the mortality rate after the first day. He found that a tumor could be felt through the rectum and abdominal walls 24 times; through the abdominal walls alone, 37 times, and through the rectum alone, 9 times, or in a total of 70 cases. During the discussion he stated that early laparotomy was indicated in all cases, as it was the only certain treatment.

One of the strongest advocates of early operation was Edmund Owen, who has written a most valuable paper[11] on the subject. He points out the necessity of early surgical treatment to relieve the strangulation of the invaginated bowel. With one exception, all who took part in the discussion, were in favor of early operative treatment, and opposed to the uncertain and dangerous treatment by injections.

Clubbe[12] delivered a clinical lecture, based on the study of 49 cases, of which 4 were reduced by injection alone; 45 were operated upon, of which 24 were cured and 21 died, giving a mortality rate of 45½ per cent. It is worth noting that in the successful cases the average duration of the disease before operation was 24 hours, while in the fatal cases it was 56 hours.

Commenting on Martin's paper, Erdmann[13] says, "It has been the fortune of the author to see 4 cases within a period of four weeks' time, during February and March of this year. And 3 cases within the three years preceding, while a typical and chronic case came under his observation a number of years ago, and 2 cases, chronic in nature, and due to malignant growths, were seen in the practice of a brother surgeon during the past year and a half. In addition, 2 cases were reported to him during the first half of the year. Such a series of cases, under the observation of a single operator, tends to the belief that the disease is much more frequent than most authors admit."

Erdmann[14] reports a series of 12 cases, of which 10 were operated upon, one recovered by the use of injections, and one in which enemata had been used, no operation allowed, died. Of the 10 operative

cases, 5 died and 5 recovered, and of the deaths, 3 were cases which were operated upon as a last resort, 2 requiring resecting for gangrene, and the third one being septic from a seven days' intussusception. The cases terminating fatally were of 2½, 3, 4, and 7 days' duration when operated upon, and of these, 3 were practically moribund at the time of operation. In a foot-note the author states that since writing his paper he has operated upon 5 more cases, all under 12 months of age.

In a subsequent paper, written in conjunction with Francis Huber, he reports one other successful case, in a child eight and one-half months of age, which was operated upon in less than six hours after the appearance of the first symptoms, and made an uneventful recovery.

At a recent meeting of the Section on Pediatrics of the New York Academy of Medicine,[15] Erdmann reported three additional operations, and presented two of the patients, all three successful cases.

According to a personal communication made to the writer, at the end of May, 1903, Erdmann operated upon 23 cases. This makes the largest number of personal cases in this or any other country. Excluding the cases which required resection, all being moribund at the time of operation, the recovery rate is 68 per cent.; including all cases, the mortality rate in 23 cases is 50 per cent.

Erdmann is a strong advocate of early laparotomy, and would try injections only within the first twenty-four hours of the disease. While formerly he advocated the production of an artificial anus in desperate cases, he is now in favor of resection, which takes only a few minutes' longer. It has been shown that the results after artificial anus are extremely bad. He did not find it necessary in any of his cases to attach the mesentery to the abdominal wall. He advocates an incision through the right rectus muscle, and claims to be able to explore the entire abdominal cavity through this incision. He found most of his cases belonging to the ileocæcal variety, and in two of his recent cases found double intussusceptions.

Successful operations in children are reported by Lees and Silcock,[16] Barker,[17] Barlow,[18] Boldt,[19] Connell,[20] Kammerer,[21] Bryant,[22] Primrose,[23] Moore,[24] Morrison,[25] Price,[26] and Dowd[27]. Howit[28] observed seven cases; four were operated, all successfully; all were under six months of age. Kocher[29] operated upon six cases. In the five successful cases resection was practised; one died after an artificial anus, made on account of peritonitis, which was present. Russel[30] treated twenty-two cases in infants; sixteen were treated by operation; twelve recovered and four died. The fatal cases were of three or four days' standing, in which the condition was not recognized until late.

A remarkable experience is Riddel's,[31] who saw three cases in a family of four children. Two were relieved by operation and one died.

Case No. 2 in my series was the second in the same family. There may be more than mere coincidence in these cases.

Rigby[32] saw seven cases in nine consecutive weeks; six were operated upon, resulting in five recoveries; only one was irreducible and gangrenous.

The chronic form of intussusception is usually due to some pathological condition of the intestinal wall, such as polypus, malignant disease or a diverticulum, and occurs principally in adults. Primary, acute intussusception in the adult is comparatively rare, and it is worth noting that while intussusception in children is readily diagnosed, in adults the condition is frequently mistaken for some other condition, especially acute appendicitis, as in the first case reported by the writer.

Munro[33] reports two cases in adults, with one recovery, after resection of 32 inches of jejunum. He reviews 72 cases of intussusception in the adult; thirty-four were acute, or chronic with acute exacerbation, 33 chronic, and in five it could not be ascertained. After reduction 21 recovered and 13 died; after resection, 17 recovered and 21 died.

Boldt[34] reports a case which was supposed to be one of ectopic gestation.

Syme[35] records a case of carcinoma of the ascending colon, with intussusception, in a woman thirty-four years of age. Resection and lateral implantation of ileum by Maunsell's method, was followed by recovery.

Auvray,[36] had a case in which appendicitis was diagnosed. At the operation an intussusception was found without any other lesion.

Boldt[37] reports a similar case in a girl sixteen years old, in which the symptoms all pointed to appendicitis, including a leucocytosis of 20,000; at the operation an intussusception of the ileum was found, necessitating the resection of 56 inches of gut, which was followed by recovery. The cause of the intussusception was found to be a polypus.

Poza,[38] reports the case of a woman, thirty-seven years of age. Enteroanastomosis was performed with the aid of a Murphy button. Seven days later a large necrotic mass was passed per rectum, which proved to be 60 centimeters of small intestine, resulting in recovery, with primary union.

Lilienthal,[39] Stead,[40] Quadflieg,[41] Helbing,[42] and Gibbon[43] each report a case of intussusception in the adult.

Meyer,[44] operated upon a chronic case which was found to be caused by a round-celled sarcoma of the intestine.

Erdmann[45] and Wainwright[46] each report a case in which a Meckel's diverticulum was the cause of the intussusception. The latter case occurred in a boy seventeen years of age. He was operated upon, the intussusception reduced and Meckel's diverticulum removed, which was followed by recovery.

Von Eiselsberg[47] reports 13 cases, eleven in adults and two in children, both of them boys six and seven years of age respectively; of the adults, six were males and five females; in addition to these, he saw two infants; in one operation was declined and in the other, after an apparently successful injection, the child was taken home. There were seven chronic, three subacute, and three acute cases. Two were of the enteric, ten of the ileocolic, and one of the ileocolic rectal variety, the last being caused by carcinoma. He found polypi, strictures, and lymphocarcinoma as the primary cause in a number of his cases. Total resection and end-to-end union was practised in twelve. In one case partial, and later, total excision was practised; nine cases out of twelve were cured after resection, and he points out that in Rydygier's series of cases there were only three cures in 12 resections, and in Gibson's cases, of 45 resections, only seven were successful.

Von Eiselsberg is a strong advocate of resection and end-to-end anastomosis.

There are a number of other papers on the subject in German literature by Ludloff,[48] Prutz,[49] and Haasler.[50] They all write on the cases from von Eiselsberg's clinic, which are referred to above. Haasler points to the fact that in Germany and France very few operative cases are recorded. He studied ten cases which occurred in the Halle Clinic in the last ten years. All of them were chronic cases, which he considers comparatively common. There was not one case in a child under

one year within the first twenty-four to forty-eight hours, and he regrets that practitioners are not sufficiently on the lookout, and that surgeons are not called to see these cases often enough. In adults, a cause for the invagination can, in most cases, be found. Polypi, Meckel's diverticulum and tuberculosis of the intestine are mentioned as causative factors.

From the above, it will readily be seen that instances of successful operations are becoming more frequent. This may be attributed principally to the earlier recognition of the disease. Up to 1885 very few cases of intussusception were operated upon. In that year Braun recommended surgical treatment as being the only proper method of dealing with acute intussusception.

It may not be out of place to consider briefly the anatomical varieties of intussusception. The most frequent form is the ileocæcal, and the rarest is the ileocolic. Besides these two forms. we have the enteric and colonic. Of the different varieties, the ileocolic is the most dangerous. In this variety, the ileum is prolapsed into the cæcum and the ileocæcal valve acts as a constricting ring. It might be well to call attention to the fact that the increase in the size of the intussusception is not at the expense of the entering gut, but that which is entered. Very frequently at autopsies one or more enteric intussusceptions are found, which very likely occur during the agony preceding death.

I shall briefly consider some of the changes which occur during intussusception. The intussuscepted intestine being constricted, undergoes certain changes which are due to the obstruction in the venous circulation. As the intussusception increases, the mesentery is pulled upon, the venous channels are obstructed, and we will find venous congestion of the intussuscepted gut. Slowly the gut enlarges, and in a short time the arterial circulation is interfered with, and soon changes occur which lead to necrosis, and finally gangrene of the entire intussuscepted portion. The congestion gives rise to one of the most characteristic symptoms of the disease—bloody evacuations from the rectum. When gangrene occurs, it is usually seen first around the neck of the intussusception. These vascular changes bring about a condition which soon gives rise to obstruction and prevents easy reduction. After several hours' adhesions are formed between the various layers which make up the intussusception, and they still further act as a barrier in attempts at hydrostatic or other reduction. If unrelieved, gangrene will develop, and the entire intussuscepted portion may be cast off in one mass. Such cases are found reported, and some of them as recoveries.

It is the writer's conviction that intussusception in children *may and should be diagnosed early.* The symptoms associated with this disease are characteristic, and if we bear in mind the possibility of the occurrence of this disease, we will never fail in recognizing it. The disease usually begins suddenly and, as a rule, in children, in previously good condition. The first and most important symptom is pain. This is usually paroxysmal and colicky in nature. Soon after the appearance of this paroxysmal pain we will find vomiting, which also recurs, at first at long and later at much shorter intervals, and may become projectile in character. With the onset of the pain, a marked change in the appearance of the patient will be noted. The child will usually be in a condition of shock, which is brought about by the irritation of the terminal branches of the solar plexus of nerves. It is the same condition which we find in the beginning of most intraabdominal injuries or inflammations. This condition of shock will be characterized by an anxious expression of the face, pale skin, rapid and feeble pulse, the skin may be covered with cold perspiration, and the respiration may be shallow. In fact, the child will present the appearance of one very seriously ill. This is of great diagnostic value, because it usually occurs in children who only a few hours previously presented the picture of perfect health. Several hours after the onset of pain, there may be an escape of bloody mucus from the rectum. The child may have had a movement from the bowels which may have been blood-stained or may have absolute constipation, dating from the time of the first symptom. At times there may be no escape of blood or of bloody mucus from the rectum until a rectal examination is made, and on withdrawing the finger, an escape of blood will be noticed.

This group of symptoms is looked upon by most clinicians as being pathognomonic of the disease under consideration. After this disease has lasted for a number of hours, we will find that the vomiting and the bloody discharge become more frequent and prominent, and that the child is suffering from tenesmus; the latter symptom is most marked in those cases in which the apex of the intussusception is in the rectum. In the beginning there will be no rise in the temperature; on the contrary, there may be a subnormal temperature. If the child should now be examined, we will find that the abdomen is not distended; in fact, the abdominal walls may be found relaxed. In the early part of the disease there will be no rigidity of the abdominal walls, and during the paroxysms of pain we may observe a tumor or fulness. On palpation a tumor may be felt, and most frequently about the right iliac fossa. Many times the tumor is on the left side of the abdominal cavity, or may not be felt at all, being hidden under the lower ribs. As remarked above, if not otherwise felt, a tumor or fulness might be detected during the paroxysms; at times a tumor might be detected on bimanual examination, and in a number of cases the examining finger in the rectum may detect the apex of the intussusception. This was present in two of the cases reported by the writer.

Should the disease be allowed to go on, without treatment, the clinical picture will change, and the changes will be brought about by the occurrence of gangrene and peritoneal sepsis. While the temperature in the beginning was possibly subnormal, it will now be above normal, the pulse becomes rapid and feeble, and the appearance of the child will be like that of one suffering from peritonitis; it will be listless, show general muscular relaxation, eyes sunken and extremities cold and cyanosed, and be absolutely indifferent to its surroundings. On examination the abdominal cavity will be found distended, and there will be rigidity of the abdominal walls; in fact, the distention may be so great that the tumor will not be felt. The vomiting in the later stages becomes almost continuous, projectile in nature, and of a stercoraceous odor.

This, I believe, is a good picture of the disease, and one that ought to be appreciated when seen.

The treatment of the disease in former years was principally mechanical, by injections and inflation. The mortality from this treatment is as high as 75 per cent., as found by Wiggin. On the other hand, we find that the percentage of recoveries after operative treatment, is daily increasing, and the great majority of the patients will recover if early surgical treatment is applied. The results from early operation are very much better than they were five years ago.

In studying the pathology of intussusception we are struck by the great similarity existing between this disease and strangulated hernia; and the writer believes that mechanical treatment in intussusception has its limitations, just as has taxis in strangulated hernia. There are very few physicians at the present time who place much reliance upon taxis, and there should be just as few who advocate mechanical treatment in intussusception. There are very few who would make more than one attempt at taxis, and there should be even fewer who will try injection or inflation more than once. There are cases of strangulated hernia in which taxis at times succeeds, and similarly, there are cases in which intussusception has been reduced by injections. But this surely, should not be an argument in favor of mechanical treatment, and the time has arrived when physicians should consider both of these conditions as *surgical*, from the very beginning. And, bearing in mind that intussusception is a surgical disease, these cases should be turned over to the surgeon at the earliest possible moment, for here again, we find the analogy between strangulated hernia and intussusception. If a case of strangulated hernia is operated upon early, all that is necessary is to cut the constriction, and relieve the strangulation. Should operation be delayed, however, we may find gangrene of the intestine, which may require the formidable operation of resection. And so it is with intussusception. If the case is operated upon early, reduction will be readily accomplished, but if operation is postponed, this will be impossible, and in order to give the patient relief, a far more dangerous operation will be necessary. In fact, the high mortality rate we still have in this disease, is due either to mechanical treatment, or to delayed operations.

In studying the mortality rate in the operative cases, we will find that it increases with every additional day, and the very high mortality is due to long-delayed operations, and to operations done where reduction is impossible, and in which gangrenous intestine has been resected.

To return to the mechanical treatment of injection and inflation, we must realize that it is unscientific, dangerous, difficult, uncertain, and antiquated. From the cases which were operated upon, we learn that reduction is difficult in some of the cases, even in the first few hours; and it can be readily seen how much more difficult it is to reduce an invagination by mechanical distention by air or water. It is the writer's conviction that all cases of intussusception should be operated upon at the earliest hour, and if mechanical treatment is tried at all, it should be employed in the first twelve hours. If mechanical treatment is decided upon, an anæsthetic should be used, after all preparations have been made for a surgical operation.

Of the two methods of distention, only one is worth considering, and that is, by the injection of water. This should be done by the aid of a fountain syringe, held not higher than three feet above the level of the patient. The child should be turned upon its face, the hips raised, and the fluid allowed to run in slowly. While the fluid is allowed to run in, the abdomen should be massaged, and occasionally it may be our good fortune to feel a previously existing mass gradually disappearing. If the distention is followed by success, there will be an escape of gas and possibly fecal matter from the rectum, and if the child is allowed to come out of the anæsthesia, a most pronounced change in its appearance will be observed; the child which only a short time ago had violent paroxysms of abdominal pain, was straining and vomiting, will become quiet go to sleep, or eagerly take its nourishment. Such a result, however, is the exception rather than the rule, and frequently we are unable to state positively whether or not the invagination is reduced. In such instances an operation should be performed immediately.

Before leaving the subject, it may be well to call your attention to the fact that the greater part of the intussusception may have been reduced, but the apex of it is left unchanged, so that the condition is practically unrelieved. Many cases are recorded in which, after an apparent successful reduction, the symptoms have returned, showing a recurrence of the intussusception. We must not lose sight of the fact that mechanical distention is dangerous because of ruptures which it is liable to produce. It may be the means of perforating a beginning area of gangrene around the neck of the intussusception, and it is certainly the cause of considerable shock in an otherwise unfavorable condition.

As said above, the writer would make one attempt at mechanical treatment, and that only in the very first hours of the disease, and he takes this opportunity of adding a word of warning regarding the administration of cathartics of any kind during this disease; if administered they not only fail to relieve, but they make the condition decidedly worse. We will find that a great number of fatal cases were those which were overlooked, and those treated by cathartics.

The objection may be raised that the patients are too young to stand an operation, but it is an indisputable fact that infancy is no bar to successful operation, and that children stand operations very well.

If a case is submitted for surgical treatment early in the disease, reduction after a laparotomy will be readily accomplished. On the other hand, if the condition is not recognized early, or operative treatment has been delayed by unsuccessful attempts at reduction by injections, reduction will be difficult, even during a laparotomy, and operations, such as resection, partial or complete, entero-anastomosis or artificial anus, may be necessary. The mortality rate from the latter operations must be very much higher for the reason that the conditions which require them in themselves, are connected with a very formidable mortality.

When a case is seen within the first twelve hours and an attempt is made to reduce the intussusception by mechanical means, all preparations should be made for an aseptic and rapid laparotomy. The patient should be anæsthetized by chloroform or chloroform and ether. Should reduction fail, or should there be doubt regarding the result, and in cases over twelve hours' duration, the abdomen should be opened at once through incision in the right rectus muscle. In most instances this incision will answer the purpose. The intussusception is brought out of the abdominal cavity and an attempt made to reduce it. This is best done by pressing upon the apex of the intussusception through the ensheathing bowel. To attempt reduction by pulling on the bowel is very dangerous, and will cause lacerations of the intestine or mesentery and at times an extravasation of fæces. In early cases reduction will readily be accomplished, and after assuring ourselves that there are no other intussusceptions, the abdomen is closed in the usual manner. Where reduction is impossible on account of adhesions between the various parts of the intussusception, and the patient's condition will permit, partial resection can be done, after the method of Barker, Rydygier, or that recommended by Erdmann,[51] in which after incision of the en-

sheathed bowel, the intussusceptum is resected and the operation completed after the method of Maunsell. The writer will not attempt to give a description of these operations, as it would carry him beyond the scope of his paper. If the intussusception is gangrenous, or the condition of the patient will permit, complete resection, with immediate union of the divided intestine, may be practised. Union can be established with the aid of sutures, the Murphy button, or after the manner recommended by Maunsell. In cases of long standing, in which reduction is impossible or gangrene is present, the condition of the patient being so bad that partial or complete resection, with immediate union of the bowel cannot be practised, the divided bowel may be left open, to be united at some future time, should the patient's condition improve. In desperate cases, in which reduction is impossible, enteroanastomosis can be performed or an artificial anus made. The last two measures might improve the patient's condition, but leave the intussusception unrelieved, to take care of itself. Enteroanastomosis excludes the intussusception and relieves the obstruction, but takes almost as much time to perform as partial or complete resection, and has none of the advantages which the last two operations afford. Artificial anus is the only operation which is left for the desperate cases, which are irreducible or gangrenous. It can be performed very rapidly, though it leaves the intussusception unrelieved, and carries with it the risk or peritonitis and starvation.

663 EAST ONE HUNDRED AND FORTIETH STREET.

## AN UNAPPRECIATED SOURCE OF TYPHOID INFECTION.*

BY P. B. BARRINGER, M.D.,
CHARLOTTESVILLE, VA.

" . . . , *en l'obligeant à tout voir, lui permet aussi de tout dire.*"—Tardieu.

THE "scenes of confusion and creature complaint," which the American traveler beholds with such wonder at every European railway station, when the doors of an incoming express are unlocked, tempts him to patriotic self-congratulation that among the good things American not least is the railway water-closet.

A call to look after a typhoid-fever patient, on a railway train, a few years ago, first drew my attention to certain possibilities of enteric infection from these same closets which have been almost ignored by the profession.

In the case in question the railway journey was one of several hours, and the diarrhœa and straining were so constant, that, in the language of the patient himself, he had been "on the stool for a hundred and fifty miles." This peculiar standard of measurement, infection in miles, doubtless first suggested the idea embodied in this paper, viz., the infection of the road-bed of our American railways through the discharge of typhoid patients traveling over the road while in the infective stage.

The infectiousness of the typhoid stool even in the early stages when patients are well able to travel and hardly know they are ill, is well-established. The prolonged presence of the *Bacillus typhosus* in the urine of typhoid convalescents, going about, is equally well known. The fact that all American railway lines use closets which discharge all fecal matter passed on the train by passengers directly upon the road-bed, is not so generally known to medical men, but it is none the less a fact.

If these things then are true, the only chance of ultimate escape for any foot of road-bed must lie in the hope that traveling typhoid patients are rare—a hope not well-founded, as the following figures will show: In the United States six hundred million railway tickets are sold annually, representing over seventeen thousand million miles of travel, to be used on the two hundred thousand miles of railway in this country. It will be seen that the average distance traveled on each ticket, *i.e.* traveled by each passenger, is about twenty-eight miles. At this rate some seven thousand passengers, each on a twenty-eight mile ticket, would be required to cover once each mile of the two hundred thousand miles of road-bed in the United States.

But as over six hundred million passengers travel each year over this same road-bed, it will be seen that each mile will be covered in this time by over eighty-five thousand persons. How long do you suppose a road-bed, receiving the discharges of eighty-five thousand passengers annually directly upon its surface, would escape infection with such travel as this?

Further light may be thrown upon this problem by remembering that the death rate of typhoid fever for the United States is 46.2 per hundred thousand.

*Read at the annual meeting of the Virginia Medical Society at Roanoke.

per annum. As only about one typhoid patient in every ten dies, this would mean some 460 cases of typhoid each year for every one hundred thousand of population.

Now, I believe that the proportion of typhoid patients that travel, either to their homes during the early stages of infection, or back to their homes during the equally infectious stage of convalescence, is very large. Contract doctors send them away from the mines, factories, etc., once a diagnosis is made; summer resorts and other hotels show them the door even on suspicion, and when we remember that the years of typhoid susceptibility are also the years in one's life when the lust of travel burns freely in the blood, we will understand why we hear of them so often on the rail. If the proportion of sick and well on the railway is anything like the proportion of sick to well shown above, viz., four hundred and sixty typhoids to the hundred thousand of population, then with eighty-five thousand passengers to the mile, annually, we would have over three hundred and seventy cases of typhoid traveling over each mile of road in the United States each year. Would not a few years of this give almost complete infection even to a new road, and if so is there any hope that any of the old road-beds in the East, twenty, thirty, forty, and even fifty years old, as they are, could remain free from permanent infection. I say permanent infection because I believe that in the well-drained but cool and moist soil under the ties and ballast of a modern railway road-bed, baptized day after day and year after year with the albuminous fluids of human excrement, the *Bacillus typhosus* once planted, in this natural culture medium, will live forever, revitalized at intervals by new infection, perhaps, but, in the meantime facultative enough to meet seasonal and other changes and remain potent. I further believe that the old trunk lines of the United States are already infected for practically their entire length, and unless some radical change is made in dealing with railway excrement this country will ere long be threaded and traversed in every direction by long and narrow but none the less deadly zones of enteric infection, a permanent and ever growing menace to national health. Here in America, in a new land, thinly populated, we have already a death rate of 46.2 per 100,000, while England, an old country, densely populated and crowded has a death rate of only 18.0. It is too much to believe that this great difference is due solely to the peripatetic watercloset, but if the closet were abolished in America, as it should be, I feel sure that the close approach of our figures to the low English death rate would surprise us.

In advancing proof of infection of these road-beds it must be borne in mind that there is at present in every community a certain, constant, and very appreciable amount of typhoid fever which cannot be traced to any known source. For several years I have worked on these cases, when opportunity offered, and I have been myself surprised at the number in which the trail led to some recent connection with a railroad.

Infection of a long, narrow strip of earth, like a road-bed, would be expected to influence two distinct classes of persons: First, those living more or less permanently along the line of road, and, second, those usually living elsewhere, whom the necessities of travel or vocation have brought into transient or temporary contact with the road and its influences.

As regards influence upon the first class, the permanent inhabitants, we turn at once in mind to the direct infection of streams, brooks, creeks, and rivers which pass under the line of road, or as a secondary consequence to the infection of springs and wells which flow from the area crossed by the infected road-bed. The danger of this class of population must necessarily multiply with the increase in travel and contamination, but so far little or no attention has been paid to guarding against such infection by those entrusted with the care of public health. As I came to this convention, my train, with closets certainly open and, perhaps, active, crossed a river not two hundred yards *above* the point of intake for the water supply of a city of thirty five thousand inhabitants. The possibilities of an acute general infection in such a city are manifest, and it may yet perhaps have its name become a by-word and a reproach among cities, as Plymouth, Maidstone, Lausen, Ashland, etc., for all the world hears of the great epidemics. In less degree this infectious influence and this danger exists for every town, village, and farm-house along every line of railroad, and the only reason we have not found it is because we have not looked. We will travel up stream ten miles to look for a house with a case of typhoid that might have produced our infection below and ignore the railway line, which parallels the stream the entire distance, and crosses it at intervals.

But immense as the possibilities of road-bed infection may be for the people along the "right of way," a danger far more difficult to avoid and none the less potent threatens the people that travel the infected road.

It has long been observed that a journey, usually a railway journey, increases one's chances of typhoid fever. Even the laity have observed this, and the family physician has the stock explanation ready in ascribing it to "contaminated water taken in travel." For some years, with doubt in mind, I have carefully observed the filling of the railway tanks in travel, and on all roads that have any claim to be called passenger lines, they invariably fill the drinking-water tanks in the cities or towns where they can get city fire pressure for prompt filling. This being the case, why should we have more fever among those who drink this water in travel than among those who drink it at home. I know that we do have more, for any practitioner with experience in towns where railroad employees form any considerable part of the population will tell you that railroad employees are particularly prone to typhoid infection. Bearing upon this subject is the fact that traveling salesmen—"drummers"—are also prone to typhoid. Within the last year I heard the president of a large corporation, employing many salesmen, make the statement that his firm had several salesmen incapacitated with fever every fall. In spite of all this I still found it hard to believe that water which was seldom or never charged with misdemeanor at home could do all this mischief on the train.

My first ray of light came from a railroad hospital where the interne told me that "nine out of ten of our typhoid cases are track men." By track men he meant section bosses and section "hands," whose labors are directed toward keeping the road-bed in good condition, taking out old ties and putting in new, leveling up the general surface and redistributing the ballast, etc. Why did this class have more fever than brakemen, conductors, etc.; they seldom took a drink of "city water," of the kind here suspected?

The report of the United States Army Commission chosen to study the causation and methods of spread of typhoid fever in the camps of the volunteer armies of the Spanish-American war had been accepted by me as proof conclusive of the possibilities of typhoid-fever infection through contami-

nated dust, so when in one hour of summer travel I saw from an observation car four gangs of trackmen in turn swallowed up in receding clouds of stifling dust I felt that I was on the right track at last for the solution of this problem. I subsequently found that these men were exposed not only to the dust and dirt thrown up by their "billies," picks, and other tools, but every half hour, day after day, they lined up beside the track to let some train pass, and then stood choked and blinded by the dust for several minutes after it had passed. Their drinking water, obtained, as a rule, from some well, spring or stream near the track, was usually carried in an open bucket, which, with its tin cup, hangs beside the track to receive its quota of the disturbed road-bed dust. Of course the high sick rate among these track men may be due simply to the fact that their water is usually drawn from the drainage area of an infected road-bed, but if this water were the sole cause we would still look in vain for the source of the infection producing travel typhoid in drummers, train crews, etc. I am convinced that railroad typhoid is traceable to one common cause. I believe the high sick rate of the track men is due to direct infection from handling the contaminated ties, earth, and dust of the road-bed, supplemented by constant exposure to the clouds of dust raised by passing trains. It is my belief that this same dust is the unappreciated source of typhoid fever infection in railway travel, as this, and this alone will explain the facts as they exist for track men, train men, traveling salesmen, and the general public alike.

The only practical cross-tie, the wooden tie, is, unfortunately, rapidly perishable, and the whole genius of railroad construction has been directed toward creating such conditions of road-bed as will best preserve the tie. To this end the track is now always well-drained, the ties are elevated on broken stone, or if that is not available, cinders from the roundhouse or yards is used. On such a bed as this fecal matter dries very rapidly, and once dry the forces of disintegration move apace.

An examination of any section of passenger road will show two distinct forms of track pollution depending upon the type of closet used on the train. The first type of closet, usually found on "day coaches" and those doing local traffic, consists of a slightly conical metal tube with a simple seat and lid at the upper extremity and open below. There is no water used in this closet, and it delivers fecal matter and urine direct and unmixed upon the road-bed about the ends of the ties. I say about, because complaint in days past by section hands and bosses against handling soiled ties has caused the car builder to give this tube an outward turn to make it clear the track, and as this brought the open end of the tube over the truck frame or stay chains we sometimes find these tubes with a double turn, outward and forward, hence the fecal matter nearly always falls on the side of such an oblique shaft, clings there, and by the vibration of the train what naturally would infect a few rods is doled out to the track for miles, and falling in very small masses is blown all over the road-bed.

The other type of closet found—the so-called railway "watercloset"—is purely an imitation affair, intended to impress by its resemblance to the genuine hygienic type, and also to keep the cold air out of the car. These are found in the better class of coaches, parlor cars, sleepers, etc. Here the open metal delivery tube has, at the upper end, in place of the simple seat, a hinged seat and cover fitted over a bowl closed below with an old-fashioned "pan" seat. On raising or lowering the lid of the closet the pan is tilted and the excrement discharged into the open tube, at the same time water is turned on, washing the tube reasonably clean. It will be seen here that water is first mixed with the natural discharge in the pan, and then the softened mass is washed out with more water. The result of this is that such discharges sink at once into the road-bed, leaving only the spattered paper pulp to mark the place of fall. It will be noted that while both closets are deadly, in that they discharge human excrement undisinfected, upon the roadway, the watercloset type makes for the saturation of the soil of the road-bed, while the simple closet gives the superficial deposits. The latter, dried, broken, and driven by the fierce blasts which sweep the track, forms a constant and appreciable organic factor in the dust which we find ever present in travel. If now the fecal matter constituting this dust chance to be that from a typhoid patient, and containing viable bacilli, we can see that the contents of the drinking tanks and cups, the fruits, candies, and other foods upon which this dust settles become at once dangerous.

The passage of a train at high speed over the rails, even in still air, creates most violent currents and draughts, particularly close to the ties, where pilot, fire-box, and numberless brake beams skim the ground and force the air out from under the car, carrying with it not only dust but even coarse particles of cinder. A wind of fifty miles an hour could not do more for the limited area covered by the ties, and this dangerous dust, once clear of the running gear that disturbed it is swept by strong lateral currents backward to afflict most seriously the rear coaches, where we pay an otherwise justifiable premium for safety.

This is my theory of infection, and while it, to my mind, harmonizes all facts known of typhoid from Pettenkofer to Widal—I put it forward now only as a working theory to explain, not epidemics, but the steady seasonal presence of typhoid all over the land, which has never yet been explained. Over 50 per cent. of all cases of this fever occur in the months of August, September, and October—these are first of all the traveling months; they are the hot and dry, and hence dusty months; they are the fruit and ice and drink months; and this, I believe, is exactly why they are the typhoid months This question cannot be settled by simple bacteriological examination of the soil. This is so difficult as to be impossible. This question is one for the clinician and not the pathologist. As throwing some light on it, will cite the following facts:

At the University of Virginia we have between six and seven hundred students, nearly all within the age limits of prime enteric susceptibility. These students come to us in September, and remain till the Christmas holidays, when they go either to their homes or to visit some city, to return in January; a large proportion of them also make a railway journey at Easter, and yet this singular fact exists—in fifteen years we have never known the Easter holidays to bring back to us a travel case of typhoid, only once in this time have we had a case follow the Christmas travel, but in the fall pilgrimage to college (one way only) we see nearly every fall one or two travel cases, and one year—'98, I believe it was—we had three.

By travel cases I mean cases in which the first manifestations appear just about a fortnight after a railway journey. Had they been infected after arrival, there would have been found subsequently a local cause and other cases would have appeared; had they been infected earlier they would not have left home; so when two or more men, living in boarding houses widely remote and using different

milk supply, show manifestations of typhoid on the same day, and that day just about two weeks after a hot, dusty railway journey of several hundred miles. I call that travel typhoid, because I cannot but believe it was acquired in travel.

If these things be true what is the remedy? Is it to ballast the road till there is no dust? I am persuaded that fæces on the cross-tie or on the surface of the ballast is in the most dangerous site for ready infection, but the contained bacillus in such a place is short-lived, while the water-soaked fæces from the Pullman which sinks down at once through the ballast, out of the sunlight and free air to the cool, moist earth to become dry only in the late summer and fall, furnishes the condition for permanent infection. Ballast, at least, harbors the infecting agent. Is relief to be obtained from the use of crude petroleum? Dust in itself, while disagreeable, is not dangerous. Coal oil will not prevent infection of the road-bed drainage area, even if it stops the dust.

The remedy lies in a retention closet which will retain safely, and without offence to the passengers, all dejecta passed on the trip, and at the end of the trip, in some suitable and approved place, these closets can be emptied of their contents and cleaned. For the poorer roads, with mediocre equipment, a good metal-lined, dry earth box would suffice, while for the better class of roads their mechanics could, without trouble, devise a retention watercloset, using a plunger instead of a pan. Such a closet would add little weight, would give no offence to the senses of passengers, and it also could deliver its material safely at an appointed place. These things are but matters of detail—the direct deposit of fecal matter which might be infected with the organism of enteric fever, cholera, uncinariasis, or a dozen other possible sources of human contagion, on the soil daily without regard to any surroundings or consequences should be forbidden. It is a hygienic anachronism and it must go. European roads, having few or no closets on their trains, escape these difficulties at great discomfort to their passengers. We can have both comfort and safety at little expense. Infected road-beds relieved of their annual supply of new infection and natural culture media will in time be starved out, so to speak, but under present conditions the menace to health grows with time, grows with increase of population, with increase of traffic, with increase of disease, is self-perpetuating, and must be, for these very reasons, stopped.

## POINTS TO BE OBSERVED BY THE FAMILY OF A TUBERCULOUS PATIENT.

By C. P. AMBLER, M.D.
ASHEVILLE, N. C.

When a diagnosis of pulmonary tuberculosis is made in a member of a family the first duty of the physician making this discovery is probably to the patient in advising him as to the course best to pursue in caring for himself and attempting to bring about a recovery. As physicians, we should listen to the likes and dislikes of the patient in so far as they do not jeopardize the health of those with whom he is to come in contact.

Frequently the patient will desire that the other members of the family are not to be informed of his condition; will, in fact, demand that the physician does not so inform them. Until the State requires notice of all cases of this disease discovered, the physician will be forced to decide whether his duty lies in listening to the whim of the patient or in taking measures to protect the other members of the family. Personally, we believe that the family should always know the facts and be thoroughly instructed as to wherein lies the danger to others.

We should take all time necessary in explaining, both to the patient and to his friends, the source of danger of infection and the means of avoiding the same. We should carefully point out that when discretion is used and directions are followed, very little danger to others exists from residing in the house with tuberculous patients, but if no regard is given to advice and directions, then there is great danger in being so situated.

Our records show that a single tuberculous patient in a family is the great exception. This does not by any means prove the heredity theory of the disease. It is easy, however, in many cases, to trace the source of infection to some other member of the family who probably died months or years before the symptoms become manifest in our patient.

To be born of tuberculous parents does not by any means imply that the child who later develops the disease inherits the same. Contact with such parent, on the part of the small child, is frequently followed by infection of the child. Very little resistance exists against infection in the young. When they are once infected, the disease may advance rapidly, or may become latent and develop only in later years of life.

It would be unfortunate indeed, and unjust to the patient, should our warning words be construed by the family as meaning that the infected member was to be looked upon as a sort of leper and shunned as such. When this occurs in a family it means that the physician has only done half his duty. He must take time to explain fully his statements. He must by no means create an aversion on the part of the family. He must seek to gain their coöperation with that of the patient. They, as well as the patient, must be made to understand that the care is used both for the advantage of the patient and for their own protection.

The coöperation of the patient can usually best be secured by showing him that he is a possible source of infection to himself, that he can infect sound lung tissue from his own sputum, if the proper regard is not given to the disposal of the same.

If physicians in general would take more time in instructing their patients and informing their families as to the source of danger, we would not have nearly so many second and third and fourth cases in the same family.

Medicines have their place in the treatment of tuberculosis, but in point of benefit to the patient, no possible medication can accomplish the good that careful, painstaking, repeated, and intelligent instruction by the physician can and will result in. Further, when a case exists in a family an ounce of prevention distributed among the members is worth many tons and years of treatment and cure.

*Disposal of Expectoration.*—The greatest danger from expectoration is that the same may become dried and be whipped or stirred up in the shape of dust to be inhaled by the patient or others. It should, therefore, always be our aim to keep the expectoration moist. If cuspidores or other receptacles are used, they should always contain liquid, preferably a strong disinfectant, while the greatest care should always be exercised by the patient to see that the expectoration is expelled into the liquid. Metal pocket flasks are convenient and are easily disinfected. The habit of expectorating into handkerchiefs is bad, and should always be discouraged. Paper napkins may safely be used if properly cared for and burned. Under no cir-

cumstances should the patients be allowed to expectorate into the open fires, grates, registers, or corners, upon carpets, rugs, or floors, or about the walks, lawns, or other similar places. Either sputum cups, flasks, cuspidores, or paper napkins should always be within reach of the patient, and should be used carefully and knowingly.

The ultimate disposal of the collected sputum should be by burning, or, after thorough disinfection, by passage into the sewer.

The insanitary, disgusting, and dangerous custom of expectorating about the lawn or over the veranda railing should be absolutely prohibited. The patient should be taught the danger of expectorating upon floors, sidewalks, or, in fact, into or upon anything except the vessel or object prepared as a receptacle for such expectoration.

When the patient expectorates at night, either sputum cups should be used or some large-mouthed vessel, containing liquid disinfectant should stand beside the bed upon a large piece of paper. The paper is, of course, burned in the morning. Napkins, handkerchiefs, and towelling should never be used for the purpose of receiving expectorated matter, and should never come in contact with the same.

*Eating and Drinking Utensils.*—It is not necessary that the patient should have separate eating and drinking utensils. All such objects should, however, be subjected to the action of boiling water after use. The patient should not use the common drinking cup or glass kept at the water cooler for the members of the family.

It can be easily demonstrated that the lips of the tuberculous patient contain upon their surface tubercle bacilli in variable numbers. This means that all objects brought into contact with his lips receive such bacilli and may be carried to the mucous membranes of others.

*Kissing.*—For the reason just mentioned, the patient should never kiss another person, especially upon the lips. Parents, in particular, are to be cautioned against kissing children.

*Foods and Breadstuffs.*—It is impossible for the consumptive to keep his hands free from bacilli. He should, therefore, never be employed in markets where foodstuffs are sold to the public, and he should not handle or prepare food for the family; especially such foods as are eaten uncooked or unwashed.

*Coughing.*—It is a fact, not commonly understood, that when a person coughs there are myriads of small globules of mucus, saliva, or sputum expelled with the expired air. This necessarily means that tuberculous patients do unthinkingly and unknowingly distribute bacilli into the air immediately surrounding them. In the open air the danger from this source is slight, but in the room it makes one of the most dangerous and difficult to overcome of any source of infection with which we have to come in contact. The breadth from the patient quietly breathing does not contain bacilli. Any one can demonstrate the danger from forcible coughing if he will but cough violently against the polished surface of a looking-glass, holding the same from a few inches to two feet from the face. Since this is true, coughing at the dining table must be prohibited, and the floors of the rooms occupied by tuberculous patients should not be covered by carpets, rugs, or mattings.

*Dust.*—Rooms occupied by tuberculous patients should be so arranged that dust floating in the air can be kept at a minimum. The patient himself should not inhale dust, and the members of the family should remember that all dust arising in apartments occupied by a consumptive is very probably a highly infected material and one of the, if not actually the most common, sources of infection to others.

*Ventilation.*—No person should sleep in a poorly ventilated room. The patient should occupy his room alone; he needs all the oxygen in the room himself and, moreover, the sleeping room of the consumptive always contains tubercle bacilli beyond the reach of disinfectants.

*Wounds or Abrasions.*—Wounds or abrasions of the skin of the healthy offer modes of entrance for bacilli. A wound (ever so small) so infected will, perhaps, never give more than slight local inconvenience, but may be the beginning of what later terminates as pulmonary tuberculosis.

*Danger to Small Children.*—We allow our little ones to creep on the floor where we walk with soiled footwear and in many homes where but slight regard is given to the disposal of expectoration. Most of these little ones are frequently putting their fingers into their mouths, sucking from them the dirt collected from the floor. Is it remarkable that intestinal diseases among children are so common? Tuberculous nodules are frequently started in the intestine of the small child in this way. Such a nodule may remain latent throughout life, or may soften and start an active general or local tuberculosis at some remote part of the body at any future time of the child's life.

*Advice to Patient by Members of the Family.*—The family should be sure that their advice conforms to that of the physician. His word should be law. Healthy individuals rarely appreciate the necessities and limits of the patient's vitality and strength. Take, for instance, the matter of walking: if the patient accompanies healthy friends, they, in the buoyance of their vigor, forget his weakness; result—the patient must bring his gait up to theirs at the expenditure of what is to him overexertion, but to them no effort whatever. The family should not "nag" the patient by always saying "don't," but should use tact and judgment, seasoned with common sense and patience.

*Public Hall and Meeting Places.*—Public halls and meeting places should be avoided by the consumptive, both for his own good and for the good of the public generally.

The slow development of tuberculosis disarms the public and the friends alike. Rarely do the friends attribute the trouble to the true source of infection. Months and years generally elapse before the symptoms become so marked as to call the attention of the party infected to the same. As a rule, the patient from whom he received his infection is long since dead, and months of good health were enjoyed since the infection occurred, hence no thought is given to the subject.

If tuberculosis were the rapidly fatal disease that smallpox is, or produced the visible disfigurement resultant from the same, we would long ago have quarantined against it. The public is always frightened at the very word "smallpox," but fails to appreciate that thousands die every year from tuberculosis where one dies from smallpox. Tuberculosis is the cause of one in every seven deaths in this country yearly.

Disinfection will do great good as a prevention, but does not compare in efficiency with care in the disposal of the expectoration.

All members of a family in which has occurred a case of tuberculosis should remember that they may have been infected at the same time the sick member was, at the same source, and that their own case may simply have been less active. All mem-

bers of such family should therefore be from time to time thoroughly examined. It is in the cases thus discovered that the percentage of cures is high. Any member of such family, discovering that he or she has a temperature record varying daily from one to two degrees between the minimum at morning and the maximum at evening, should be very suspicious of tuberculosis unless the variation is otherwise satisfactorily explained.

The head of the family should learn in detail exactly what the physician has advised about these tuberculous cases and should see that such directions are carried out carefully. All physicians should have printed directions for both patient and family to observe; and finally, if the patient does not and will not follow such directions, he should in order to protect the other members of his family, be removed from home and placed in some institution in which such cases are cared for.

We have a great duty to the healthy members of the family, and should not lose sight of the fact in advising the tuberculous patient. We can protect the healthy when we cannot save the dying.

---

**The Sterilization of Catgut by Claudius' Iodine Method.**—Martina has subjected this method to a careful series of tests and reports very favorably on it. The preparation of the catgut is very simple, consisting of immersion of the gut, as it comes from the maker, in an iodine solution for eight days, at the end of which time it is ready for use. The iodine solution, in which the gut is sterilized and kept, is made as follows: One part of potassium iodide is dissolved in a little distilled water, then one part of iodine is added and the solution made up to one hundred parts with distilled water. Claudius originated the method about a year ago, and has since published the opinions of a number of well-known surgeons, which were all favorable. Martina has investigated the product obtained from all points of view and praises it highly. An elaborate series of cultures made under many different conditions showed the absolute sterility of the gut, and also that the iodine retained makes it markedly antiseptic without, however, being sufficient in amount either to produce local irritation of the tissues or involve any risk of iodine poisoning. Claudius advises that before use the gut be placed in a three-per-cent carbolic solution, but the author does not recommend this, as it diminishes the antiseptic value of the iodine. Comparative tests showed that iodine catgut possesses about one-seventh greater tensile strength than the raw material, though it gradually loses this property unless the iodine in the solution be kept up to full strength. The method, therefore, offers an extremely simple and inexpensive means of preparing gut which can be easily preserved in a sterile condition, and is not only aseptic but antiseptic. Its disadvantages are the unpleasant odor emitted by the iodine solution while exposed to evaporation during the operation, the fact that if kept together with instruments the vapor attacks these, the yellowish color the gut imparts to the hands and dressing, and the fact that it is absorbed in six to seven days so that it is not adapted to use under circumstances in which greater permanence is desired.—*Deutsche Zeitschrift für Chirurgie.*

**Observations on Auscultation in the Cardiac Region.**—Syllaba points out that the so-called Flint murmur may give rise to serious diagnostic errors unless care be taken to make repeated examinations of the patient, preferably after rest in bed and digitalis. The true Flint murmur is largely dependent on variations in blood-pressure, and when this is high, as after the administration of digitalis, the conditions for its production become much less favorable. Although patients exhibiting this sign are likely to suffer more than those without it, still it is not necessarily of bad omen, and but little prognostic information is to be derived from it. The systolic murmur at the apex frequently accompanying arteriosclerosis, and nephritis is due to a relative insufficiency of the mitral valve; when constant, an organic insufficience; when evanescent, a functional insufficience may be assumed. An important feature in the production of relative insufficiencies is the dilatation of the muscular ring about the auriculoventricular ostium; when this is enlarged, owing to ventricular hypertrophy, the valve does not receive its legitimate assistance and regurgitation follows. Thomayer's friction sound consists of a cardiorespiratory sound heard over the upper part of the sternum in old persons. It is audible during inspiration, mainly its latter half, but not during expiration. It occurs synchronously with systole. Thomayer believed it was due to inflammatory roughening of the adventitia of the large vessels just above their exit from the heart, but this has not been confirmed by autopsy. The author describes three forms of pseudopericardial murmurs. The first is due to the well-known extrapericardial pleurisy, which affects mainly the lingula of the upper lobe of the left lung. A much less common form is due to a perihepatitis of a serofibrinous nature, in which the cardiac movements cause friction sounds between the liver and diaphragm. The last resembles the first, but is due to a pleurisy affecting the mediastinal portion of the right lung.—*Zeitschrift für klinische Medicin.*

**The Arch of the Palate.**—In concluding an elaborate paper on palatal growth and development, H. L. Swain notes that it is possible by deforming processes which artificially alter the shape of the skull to produce a change in form and shape of the hard palate. Under the above mentioned conditions the septum seems to conform itself to the altered development of the rest of the face, rather contrary to our previous ideas regarding the habits of this structure. If, however, from arrested or retarded development of the superior maxilla the palate fails to descend to its proper level, a bent septum is as liable to be produced as when the palate is arched too greatly by an unnatural narrowing process. Hence a palate of perfectly normal height as compared to breadth may produce a bend in the septum. Swain also contends that in considering the various causes which produce the abnormalities of the palate, we must lay more stress upon the lack of proper aëration of the maxillary sinuses retarding their development and hence that of the whole superior maxilla. He believes that the conservation and general care of the deciduous teeth help to produce a normal horizontal curve in the hard palate and lessen the tendency to narrowing.—*The Laryngoscope.*

**The Treatment of Ménière's Disease.**—J. M. Bradley reports a case successfully treated by the use of the hydrochlorate of quinine in solution. Starting with 21 grains in twenty-four hours, it was found that by increasing to 24 grains and keeping at that point for one month, the spells were thoroughly controlled. The strength of the solution was then reduced to 3 grains to the drachm, taking one drachm in the morning, 2 at noon, and 3 at night, without the recurrence of paroxysms of vertigo. After ten days the dose was reduced to 15 grains in twenty-four hours without return of the spells. Finally the dose was reduced to 12 grains in the twenty-four hours, which thoroughly controlled the paroxysms. This dose being as small as may be given without recurrence of the spells, and still not large enough to cause an aural congestion, it will be the permanent dose, in this case, and the patient will be required to take that amount for an indefinite time. By this method of treatment the number of paroxysms was reduced from two each day to one in three months.—*Therapeutic Gazette.*

**A Cheap Method of Removing Silver Stains from White Fabrics.**—Moisten for two or three minutes with a solution of bromine 5 in water 500. Then rinse in clear water. If a yellowish stain remains, immerse in a solution of sodium hyposulphate 150 in water 500. Rinse in clear water. This formula has been found especially useful for hospitals and laundries.—*Revue Médicale de l'Est.*

## SOME THOUGHTS CONCERNING THE PARASITIC ORIGIN OF CANCER.

MUCH has been written during the past two or three years with respect to the parasitic origin of cancer. Clinician and scientist alike have advanced their convictions concerning the fundamental etiology of this disease. In the main the staunchest advocates of the parasitic theory have been the self-proclaimed discoverers of the causative microorganism of malignant growths. The data offered by them in support of their claims relate almost exclusively to the demonstration by various methods of the supposed microorganisms in cancer tissue. To the unprejudiced mind it is evident that the mere histological demonstration of microorganisms in malignant tissue is small proof of their etiological relation thereto. Recent advances in biology force this conclusion. Our present knowledge conclusively shows that during infection definite and, in the majority of instances, specific biological relations exist between the infecting microorganism and the tissues of the infected individual. That is to say, during infection certain substances are produced by the tissues of the infected individual. These substances are in various ways antagonistic to the infecting microorganism, and in the majority of instances to that microorganism only. They are known as bacteriolysins, agglutinins, etc. They can be obtained, although not isolated from the body tissues and submitted to experimental examination. Not alone does this invariably occur in the presence of bacterial infection. Such relations are also known to be universally present following the inoculation of various substances, such as bacterial toxins, various body cells, and many chemical compounds. Under the latter conditions there arise in the tissues of the inoculated individual antitoxins, cytolysins, hæmolysins, precipitins, etc. These facts are universally admitted by all who are competent to form an opinion with respect thereto. It is apparent therefore that he who would receive recognition as the discoverer of the causative microorganism of cancer must accomplish one of two objects, viz., (1) Produce proof in accordance with known facts relative to the biological relations existing between his microorganism and the tissues of those suffering from cancer, or (2) demonstrate that such biological facts are false. This is the more forcible since the careful pathological study of malignant tissue renders it somewhat improbable that such relations can ever be shown to exist between any microorganism and the tissues of cancer patients.

In this connection it is interesting to consider the statements of one of the most recent advocates of the parasitic theory. Feinberg announced, in the *Deutsche medicinische Wochenschrift*, 1902, No. 11, that he had discovered the causative microorganism of carcinoma. This he claimed to demonstrate in fresh carcinomatous tissue by a special staining technique. In the *Wiener klinische Wochenschrift*, 1903, No. 45, he publishes a second article on this subject. Here it is stated that this parasite is a protozoa, belonging to the special class of sporozoa. According to the researches of the author, protozoa are to be differentiated microscopically from the cells of the human and animal body essentially by the minute anatomy of the nucleus. The nucleus of the latter is made up of a nuclear membrane, a nuclear framework, a nuclear protoplasm and nucleoli. In contradistinction, the nucleus of the protozoa as a class consists of a nuclear membrane, a nuclear protoplasm, and a compact mass of chromatin substance. In the sporozoa, however, the nuclear membrane is wanting. Hence in them the nucleus appears merely as a mass of chromatin substance surrounded by nuclear protoplasm. Furthermore, the nuclei of the sporozoa and the cells of the human and animal body are different in staining reactions. By these means the author seeks to establish as sporozoa the bodies which he describes in carcinomatous tissue. This microorganism he names the "Histosporidum carcinomatosum." It is capable of vegetation only in the epithelial cell. Outside the human or animal body it exists only in the form of spores. The development of the parasite in carcinomatous tissue may be followed by the aid of a special technique. This microorganism is not capable of producing infection when directly transmitted from man to man. In order that it may produce such an infection a sporulating stage outside the body is necessary. So-called "cancer pearls" are none other than this parasite surrounded by a mass of cancer cells. The biological relations between this parasite and the tissues in general of the human and animal body are *nil*. This is so because it can vegetate only in the epithelial cell. In the presence of this parasite the epithelial cell loses its normal form, enlarges its nucleus, and becomes simpler in construction. In this way it is transformed into the cancer cell. This is not a degenerative process on the part of the epithelial cell, but an endeavor to combat the parasite. This sporozoa produces no toxin. Hence, under its influence the cancer cell undergoes indefinite multiplication. This excessive multiplication of the cancer cell reacts upon itself. From mere overgrowth it loses its vitality and degeneration occurs. Metastases are due to the direct transmission of the cancer cell inclosing the parasite from one portion of the body to another. Sarcoma is due to another protozoa. This is named the "Histosporidum sarcomatosum." It can vegetate only in the connective tissue cell. It is entirely analogous in its action to the parasite of carcinoma. In support of all of these latter statements no proof in fact is offered. It is stated that by analogy they may be assumed.

Viewed from the standpoint of strict analysis, these claims are to be separated into two subdivisions: (1) The demonstration of the supposed para-

site in carcinomatous tissue. (2) Theoretical reasoning concerning the specific etiological relation of the parasite to the disease. Observations of numerous investigators show that the data offered in support of the first contention are open to severe criticism. It is extremely doubtful whether, on the basis of minute anatomy and staining reactions, a differentiation is possible between protozoa and the cancer cell in its various forms of degeneration. Concerning this phase of the subject, however, the author's endeavors deserve no condemnation. They are undoubtedly painstaking demonstrations concerning a debatable subject. Hence they are calculated to stimulate research in a field where such is greatly to be desired. The endeavors to establish the etiological relation between the supposed parasite and carcinoma are less praiseworthy. Here no demonstrations are offered in support of the claims made. Analogy is advanced whenever it can be advantageously utilized. When this is impossible fanciful assertions are made which are in direct opposition to universally acknowledged biological facts.

No unbiased observer conversant with the situation denies the possibility of the parasitic origin of cancer. Unfortunately the arguments in favor thereof have been usually brought forward by those whose field of research is limited, when we consider the many lines along which investigation must be conducted in order that the etiology of this disease may be definitely solved. Thus the arguments hitherto advanced lack the rounded-out character which alone can command respect. They have been essentially destructive rather than constructive. For these reasons the MEDICAL RECORD has been obliged to withhold its support. The present vital need is a systematic combination of effort directed toward this protean subject. Such a necessity has been frequently emphasized in these columns. Nor alone must this be effected with respect to the individual fields of research. The pathologist, the bacteriologist, the biologist, the physiological chemist, and not less the clinician, must join issues in order that the final goal shall be attained.

## ITCHING AS CAUSE AND CONCOMITANT OF DISEASE.

IN the *Medical News* Dr. E. B. Bronson says that itching has its seat in the simple nerve endings which subserve the contact sense, which is a very different thing from the highly specialized sense of touch. Smarting and burning, on the other hand, are sensations allied to pain, and also form an adumbration of the temperature sense. That, however, the sensation of burning in causalgia is allied to itching is shown by the latter not infrequently preceding or following the attack. Pruritus may occur reflexly, as itching of the anus from ascarides in the rectum, of the end of the penis from stone in the bladder, etc. It also occurs associated with internal tumors, especially the malignant. Sometimes it occurs as a pure neurosis and may affect the distribution of a single nerve. It may be symptomatic of hysteria or neurasthenia, and it may have a psycho-sensory origin.

Whether pruritus be the first symptom or not it is always a factor aggravating the disease, and Bronson believes it is oftener than is generally supposed the primary factor. Thus in pruritus ani and vulvæ the physician seeing the case after an eczema secondary to the scratching, has developed, is apt to attach undue importance to the eczema and to look on the itching as one of its symptoms. Where an eczema is limited to these parts and is attended by excessive itching, in most cases the itching is the primary trouble. Some authorities regard kraurosis vulvæ as secondary to the scratching of the parts, and there is abundant evidence that such a sequence does exist in many inflammatory reactions of the skin. Apart from infectious conditions distributed by scratching, many pure vasomotor disturbances, with more or less decided trophic changes, arise as "scratch effects," *e.g.* "flannel eczema," and the so-called papular eczema.

In the treatment of all pruriginous diseases the relief of the itching is of the first importance. The underlying hyperæsthesia will be alleviated only when its underlying general conditions are discovered and removed. As regards local treatment, our first care should be the avoidance of all irritant contacts. The skin should be protected from changes of temperature, excessive dryness or scaliness, irritating discharges, and from scratching. In place of the last, firm pressure on the skin may be made, or the nails may be drawn with some force but not violently over it. The rationale of many of the antipruritics is their substitution of another sensation for itching. Judiciously applied when there is not too much inflammation, they often give relief. Perhaps the most generally serviceable remedy is menthol, in ointment, in oil, or as a dusting powder, but most effectively as a two to four per cent. alcoholic solution. Thymol or chloroform (the latter being especially serviceable when urticaria is present) may be added. Thymol is in some degree anæsthetic, and is especially useful in certain severe and persistent itchings, its anæsthetic action supplementing the cooling action of menthol. When applied for some time hot water is decidedly sedative, particularly in itching around the anus and genitals. Many antiseptics (notably corrosive sublimate and carbolic acid) are antipruritic and anæsthetic to the skin. Indeed, of all local antipruritics carbolic acid is the most reliable and lasting. A 25-per-cent. solution used not oftener than once a day is suited more particularly to limited areas of pruritus where inflammation is not prominent, but weaker solutions may be used over larger areas. There are no definite internal antipruritics. The bromides are not only useful, but sometimes, when there is great hyperæsthesia, indispensable. In very severe cases the cautious inhalation of chloroform relaxes spasm and has not the after-effects of pilocarpin, gelseminum, and atropin, which last in large doses will sometimes abort a violent urticaria, but is not often to be recommended. In toxic urticaria (particularly the chronic or recurrent), in which the attacks are presumably connected with toxin formation in the economy, antiseptics such as creosote or the salicylates in full doses sometimes seem of decided benefit. In simple urticaria following drugs or errors of diet, an emetic, or later a saline purge, usually affords speedy relief. In pruritus senilis harsher methods of treatment (such as vigorous rubbing) can be tolerated than in ordinary essential pruritus. Electricity (particularly in the forms of faradism and the static

electric brush) has been found especially useful. Cannabis indica internally in full doses is sometimes beneficial, and strychnine is decidedly appropriate. In pruritus hiemalis all dietetic errors should be carefully avoided, the surface (particularly the legs, where the disease is worst) should be protected from cold, and at night an antipruritic (preferably alcoholic menthol or thymol) should be at hand. Salve should be applied daily to points of excoriation liable to become the initial focus for eczema. As the skin is apt to be dry, cold cream should be rubbed in, especially after the bath. In the even more troublesome bath pruritus the bath and room temperature should be comfortably warm, only the blandest soaps, such as the superfatted Baby Soap of Eichhoff, should be used, and those sparingly. After the bath the skin should be thoroughly dried with the softest towel and the least possible friction, and a little cold cream should then be applied. Arsenic internally occasionally is beneficial. In pruritus around the anus and genitals, while search should be made for more or less distant sources of irritation and casual general conditions (lithæmia, neurasthenia, diabetes), usually more direct measures of treatment yield a quicker return. When inflammation is present, emollients (aluminum acetate solutions, simple Lassar paste without salicylic acid, with two to three per cent. of carbolic acid or with ten per cent. of orthoform, perhaps preceded by cocaine, may answer better. When itching is intense cocaine is sometimes indispensable, but it is not a good remedy for prolonged use, as continued it produces vascular atony and an increased disposition to hyperæmia. Orthoform in powder is often useful on abraded fissures of the anus or vulva. On account of the starch it contains, Lassar paste is preferable to other ointments in this region. Hot water sometimes has an excellent effect, especially in traumatic or inflammatory thickenings; the temperature may be gradually raised to 110°, and continued several minutes. The sovereign remedy, however, in pruritus ani and vulvæ is, however, carbolic acid, a single application of the 25 per cent. oil often affording relief for an entire night. Not more than one or two applications a day should be used. In some rebellious cases silver nitrate (5 to 30 grains in water or sweet spirits of niter) produces a good effect. Silver nitrate is also very useful in pruritus of the scrotum. The author passes in review the other remedies in vogue, but only to reject them.

---

### The Leg and Foot in Relation to Marching.

The *Journal of the British Royal Army Medical Corps*, November, discussed this subject. The remarks of our contemporary are based upon an article written by Boigey, a French army surgeon, which appeared in *Le Caducée*, June 20, 1903. Opinions in regard to the ideal conformation of foot and leg to fit a man for marching vary considerably. Some hold that a flat foot should be almost sufficient cause to disqualify a man for service in the infantry, while others think that "spindle legs" should act as a bar to those desiring to become foot-soldiers. Boigey considers these points in their logical and anatomical aspects. He ventures the prediction that if we could see those who competed in the foot races and games of prehistoric times, we should be probably astonished with the anatomical conformations of the contestants, and yet walking or running were the main modes of locomotion in those days. Again the feet of negroes at the present time, who are notoriously good walkers, are flat. The human foot is composed of three distinct parts—the tarsus, metatarsus, and the toes. The essential feature in the foot of a good walker is width of tread. The feet of all the lower races show a much wider tread than those of Europeans, so that what is termed among us a flat foot is rather the rule with them than the exception. In other words, in respect of arching, the foot of the negro is intermediate between the highly vaulted foot of the European, and the very flat or expanded foot of the ape. To construct an ideal foot for the foot-soldier, it is necessary to critically examine the tarsus, bone by bone, both in our own race and the negroes. Thus the astragalus is more spread out in the lower races, than in the higher. In these latter the articular surfaces are comparatively small. From these characters it follows that the astragalus more fully overhangs, and is a more perfect keystone to the plantar arch in the former races than in the latter. The length of the os calcis is in direct relation to marching aptitude. It is noticeable that climbing animals have a comparatively small calcaneum, and among the monkeys, those which habitually walk as well as climb, this bone is much larger than in those who are essentially climbers. Anthony has described the apophysis of the calcaneum as the true support of the good walker, and among the lower races it is more developed and nearer the ground than among ourselves. In short, the larger and more prominent the heel, the greater is the fitness of the foot for marching. The study of the plantar arch is intimately associated with that of the angle at which the calcaneum rests on the ground. In all the lower races this angle is very small; it is greatest among adult Europeans, especially those with high insteps. The comparative study of the scaphoid in different races gives little information. Its inner border—that is, the tuberosity—is more developed and nearer the ground in the lower races; similarly the glenoid cavity by which it articulates with the astragalus is shallower in whites than in negroes. The tarsus best fitted for walking and marching is that which is firmly rigid and well-braced together by strong ligaments. It may be compared to an arch supported on three pillars, which are the os calcis and the heads of the first and fifth metatarsal bones. Its great essentials are strong plantar ligaments and the astragalus placed exactly on the summit of the arch, for it to transmit the weight of the body evenly to the three supports of that arch. One can form an idea of the right position of the astragalus in normal subjects by drawing a perpendicular line along the axis of the tibia which will coincide with the anatomical axis of the foot. In other words, if the internal malleolus and the tuberosity of the scaphoid do not overhang the inner portion of the foot the subject may be deemed well-fitted to be a good marcher.

Dr. Boigey's views are certainly instructive, and, on the whole, there is no reason to believe that he is not correct in the deductions he draws from the conformation of the leg and foot in relation to marching. The best form of foot, according to Dr. Boigey, for a foot-soldier is one in which the axis of the leg coincides closely with the anatomical axis of the foot. Prominent muscles on the calves, which are characteristic of the athletic white man, are not necessary to be a good walker. The mechanical value of a muscle must not be estimated by its apparent volume, but rather by the weight of contractile substance in this mass. The legs of negroes contain proportionately more contractile

substance than do the legs of the white, which makes the members of the black races, as a rule, very good marchers.

### Investigations into the Cause of Plague in Sydney.

Dr. J. Ashburton Thompson, the President of the Board of Health, New South Wales, who some time ago made investigations in regard to fleas as a cause of disseminating plague, has recently published an elaborate report on the subject, the main features of which are given by the Sydney correspondent of the *Lancet* in its issue of November 21. "Prefacing his reply," says the *Lancet* correspondent, "the statement that the events of the epidemic of plague in Sydney in 1902 justify and enforce the advice which was given in the report on the outbreak of 1900, Dr. Ashburton Thompson proceeds to discuss the causes of the maintenance and spread of plague. The observations of 1900 that the epidemic was not caused by direct communication with the sick, nor by diffusion of infected articles, nor by place infection, have been confirmed and amplified. The evidence in support of the theory that the rat is the sole source from which infection is communicated to man has been largely supplemented, and the attention of the authorities is now being given to determine the species of fleas which infest rats in Australia, to variations in their frequency on rats at different times and to examine into their ability to bite man. The President of the Board of Health concludes the preface to the report by emphasizing the fact that the promise of safety for the future lies neither with attempts to prevent the importation of plague-infected rats, which must fail from time to time, nor with attempts to exterminate the rats infesting the locality to be defended, which have been found to be practically impossible, though both of these measures have their valuable uses. The really safe course lies in habitually excluding rats from inhabited premises."

Dealing with the origin of the epidemic, the only hypotheses worth serious examination in the opinion of the Board of Health are the two following: Either the epidemic depended on a recrudescence of the epizootic of 1900 or upon a second epizootic set going by newly infected rats. As to the former, the health department had reason to believe that the epidemic of 1900 died out in the course of that year, but the evidence gathered was insufficient to establish the fact. Still, the recurrence was apparently too long delayed to have been a recrudescence, and the balance of evidence at Sydney appears to tell in favor of reimportation. Practically the local authorities have decided that while there is no pathological evidence that man is infected by food, there is abundant testimony that he is usually infected by inoculation, and that the agent between the rat and man is the flea.

### The Army Canteen Question.

The abolition of the army canteen, brought about by the efforts of well-meaning but misguided members of the Woman's Christian Temperance Union, has been made the subject of severe criticism in the report by General Young, chief of the staff to the Secretary of War, which has been published recently. In the course of his remarks General Young says: "Special attention is invited to the incisive comments of department commanders upon the demoralizing effect of the operation of Section 38 of the Act of February 2, 1901, which prohibits the sale of beer and light wines in post exchanges. This law has now been in operation for over two years and a half, and has been fairly tested. Reports received from officers of all grades throughout the army who have had practical experience in supervising and observing post exchanges under present conditions exhibit practical unanimity of opinion as to the evil effects of this restriction. These evil effects show themselves in increased drunkenness, increased desertion, and generally increased insubordination. In addition to these considerations of morality, discipline, and health, there is a further one advanced by the Commanding General Department of Texas, that the soldiers' rights and privileges should not be curtailed simply because he is a soldier."

The entire matter lies in a nutshell. A certain proportion of the rank and file of the army, like their fellows in civil life, will drink spirituous liquors, and if they are unable to obtain these at the canteen they will procure them elsewhere. At the canteen the products offered were of good quality, and drunkeness or excessive drinking was prohibited. In the present state of affairs, these soldiers who desire refreshment of an alcoholic nature have perforce to go outside the lines to satisfy their wants, and, in the nature of things, do not get a good article, nor is excessive drinking restricted. The consequence is, as officers of the army almost to a man unite in stating, drunkenness and vice are far more frequent than was the case when the canteen was in existence. Officers should be—and undoubtedly are—better judges as to the situation than are the women reformers, excellent though their intentions may be. Alcoholic beverages do more harm than good, and soldiers would, perhaps, be better mentally and physically if they abstained altogether. But as they will not do so, it is a question of choosing the lesser of two evils, and as the canteen has been proved the lesser, it should be reëstablished.

### The Indorsement by Laymen and Clergymen of Patent Medicines.

Dr. S. A. Knopf has recently written a pamphlet, issued by the Committee of Tuberculosis of the Charity Organization Society of New York, in which he draws attention to the frequent indorsement of patent medicines and other secret remedies by clergymen and other persons of position and prominence. The writer considers that ministers of all denominations should pause to think of the probable consequences ere they allow their names to be thus used for advertising purposes. Further, he is convinced that if they were aware of the fact that many of the advertised patent remedies contain as much as 30 or 40 per cent. of alcohol, and often other dangerous ingredients, they would refrain from indorsing the use of medicines, of whose composition they have not the least idea. Dr. Knopf also criticises in strong terms the same procedure on the part of statesmen and senators, and is especially severe on the custom of religious newspapers of lending their columns to the advertisement of nostrums and patented remedies of all sorts. The American public is ever too ready to be beguiled by the wiles of the patent-medicine manufacturer. The taking of remedies has become a second habit with a large proportion of the population of this land. It has been proved on numerous occasions that many of these medicines—witness headache powders—not only do no good but positive harm. As Dr. Knopf remarks, a large amount of alcohol is contained in many of the advertised patent remedies. It is then more than unwise of clergymen and other educated men that they should deliberately recommend the use of a remedy of whose composition

they are completely ignorant. Ministers would seem to be imbued with the belief that they are competent to judge as to the merits of a therapeutic remedy, and have even been known to be so confident in their medical knowledge as to prescribe for suffering members of their fold. It should be pointed out in the plainest manner possible that in indorsing patent medicines they exceed the scope of their duties, to the probable detriment of those who are foolish enough to be influenced by their advice. Dr. Knopf's pamphlet is strongly recommended to the consideration of clergymen, statesmen, senators, and others who are in the habit of allowing their names to be appended to laudatory advertisements of patent medicines and secret remedies.

---

### The Antiseptic and Germicidal Properties of Glycerin.

Dr. M. J. Rosenau, Director of the Hygienic Laboratory of the Public Health and Marine Hospital Service, has published in Bulletin No. 16 the result of his investigations as to the antiseptic and germicidal properties of glycerin.

When working upon the bacteriology of vaccine virus, the fact became clear to Dr. Rosenau that the germicidal value of glycerin had been overestimated. The director and his co-workers, during the past two years, have made a careful study of the question. These studies were considered under three heads: (1) The antiseptic power of glycerin was first determined; that is, its property of restraining bacterial growth and the amount required to prevent putrefaction and fermentation. (2) Its exact germicidal value was determined; that is, the amount and time required to destroy pathogenic and saprophytic bacteria, both spore-bearing and non-spore-bearing varieties. (3) On account of the great importance of tetanus as a contaminator of vaccine virus, an extensive series of special studies were made to determine the effect of glycerin upon the spores of this organism.

The conclusions reached as the result of these investigations were as follows: Glycerin as an antiseptic. Small quantities of glycerin, less than 10 per cent., added to nutrient media, have well-known powers of favoring the growth and multiplication of many forms of bacteria. The presence of 50 per cent. of glycerin will restrain all bacterial growth. Less than this amount cannot be depended upon for the preservation of vaccines and other organic growths. The antiseptic power varies for the different glycerins. For instance, some restrain all growth and development when present in the proportion of 43 per cent.; others require 49 per cent. No evident growth or multiplication of bacteria takes place in nutrient media containing 32 per cent. of glycerin, but molds grow in stronger percentages., viz., 40 to 49 per cent. In order to prevent the growth and development of pus cocci at least 33 per cent. of glycerin must be present. This is more than that required to restrain the growth and multiplication of the other eighteen pathogenic and saprophytic bacteria tested.

Glycerin as a germicide: Glycerin has a distinct, though exceedingly feeble, germicidal action. It probably acts by virtue of its great affinity for water, abstracting this substance from the germ. As a rule, glycerin destroys the micrococci of suppuration, whether these be in pure culture or in the pus itself, within two weeks. This action, like that of all germicides, depends for its activity upon the temperature. Pus cocci may live in glycerin for months in the ice chest. They would die in a week at the body temperature. Glycerin seems to be a selective poison for the bacillus of diphtheria, which in all the experiments died much more quickly than any of the other organisms tested. The bacteria of the typhoid and colon group often show a marked resistance to the effects of glycerin in strong proportions. Glycerin asserts its greatest germicidal effects during the first twenty-four hours. The remaining members of the colonies which resist its action for the first period succumb very slowly. Glycerin in all proportions has practically no effect upon endogenous spores. Anthrax spores have been kept alive and virulent two hundred days in the stronger percentages and at warm temperatures.

Tetanus in glycerin: Tetanus spores in pure culture, freed of all organic matter and washed free of toxin, may lose their virulence in glycerin in thirty days at the body temperature, but they live for months at room temperature or in the ice chest. Glycerin, therefore, cannot be depended upon to purify vaccine or other organic matter containing this contamination. The virulence of the spores is lost long before they actually die, for they still retain the power of growing and multiplying if placed under favorable conditions. Under these circumstances they also regain their original pathogenic properties.

Glycerin has practically no effect upon tetanus toxin: Such toxin added to glycerin was found to be active for sixty days at the body temperature, and one hundred and eighty days at room temperature, or in the ice chest.

It may then be definitely stated that the experimental work of Dr. Rosenau and colleagues has shown the germicidal and antiseptic properties of glycerin to be but very feeble.

Other substances, such as chloroform vapor, chloretone, potassium cyanid, carbolic acid, formalin, etc., have been substituted for glycerin in the manufacture of vaccine virus, with more or less success, and as Dr. Rosenau remarks, "it is possible that one of these more energetic germicidal substances may be found to be superior to glycerin for this particular purpose in commercial practice."

Dr. John Anderson, speaking on the subject at the recent meeting of the American Public Health Association, referred to the statement of Green of England in which he said that by the use of chloroform vapor the crude pulp was freed from non-spore-bearing germs in from a few hours to seven days. While the active agent of the vaccine remained potent as long as the glycerin controls, and in six cases longer. This method of preparing is superior to the use of glycerin for the same purpose, in that, by the quick elimination of the extraneous bacteria, much time is saved. In hot countries where vaccine virus does not retain its potency for any length of time, or when, as in case of epidemics, sudden calls are made for large quantities of the virus, its composition with chloroform would render this mode of preparation especially valuable. Chloroform being of a very volatile nature, might be allowed to evaporate from the vaccine under careful aseptic precautions after being allowed to act as long as desired.

---

**Apomorphine Hydrochlorate as a Sedative and Hypnotic in Acute Alcoholism.**—Dr. Paul E. Becket of New Orleans concludes that (1) strychnine counteracts the depression of the heart and respiration which follows the use of apomorphine in frequent doses. (2) It acts as well in delirium tremens as in other conditions of alcoholism, and is indicated in these cases. (3) It is better to begin with a small dose (about gr. $\frac{1}{60}$) and increase it, if necessary. —*New Orleans Medical and Surgical Journal.*

## News of the Week.

**New Hospital for the Bronx.**—The plans for the new Fordham Hospital, to be built by the Board of Trustees of Bellevue and Allied Hospitals for the accommodation of that section of The Bronx lying between One Hundred and Seventy-second street and the city boundary, have been completed by R. F. Almiral, the architect. The new hospital buildings will cost about $550,000, and will occupy four acres, to be purchased from St. John's College, at the junction of Crotona avenue and the Southern Boulevard, at which point Cambreling avenue ends. The institution will comprise a group of four buildings, so disposed that the hospital building proper faces the Southern Boulevard, on the eastern side of the grounds. The Nurses' Home will also face the Southern Boulevard. A third building, the power house and laundry, occupies the northwest corner, while on the southwest corner will stand the fourth building, comprising the ambulance barns, stables, and the morgue. The six medical and surgical wards will accommodate 150 patients, and provision has been made for two additional wings similar to those now to be built, when the growth of the city requires them. The wards are provided with fire-escape balconies, six feet wide along the rear and facing the southwest, designed for use as outside balconies by the convalescent patients. Each ward is also provided with a sun parlor at its southern end. The dormitory building for the nurses, to the north of the hospital, is 56x43 feet, five stories high, and provides sanitary accommodations for forty nurses. The first floor is taken up by a classroom, sitting room, and reception hall, which may be thrown into one by sliding doors. The morgue has accommodations for twelve bodies, and contains autopsy room, refrigerating room, undertaker's room, and a small chapel. The force system of ventilating the hospital is used. The air is first filtered through an accordion screen, and then allowed to circulate in air chambers, where it is tempered by radiators. The blower then sends the air through ducts, where it is slightly dampened and then allowed to circulate through the various rooms. Air chambers at the top of each room are provided with fans for driving out the impure air. The rooms are heated by radiators. The refrigerating machinery consists of a mechanical brine plant and an ice manufacturing machine. The entire hospital is fireproof. The partitions are of terra cotta brick with clinker concrete arches. The floors of the operating rooms are tiled, while the surgical wards have composition floors and the medical wards wooden floors. The board of trustees plan to begin construction of the new hospital early next year and to finish it, if possible, before autumn.

**The American Röntgen Ray Society** held its annual convention in Philadelphia on December 10 and 11. On the first day, Dr. Charles Lester Leonard of Philadelphia read a paper entitled "The Results of the Röntgen Method in the Diagnosis of Renal Calculus." He dwelt upon the dependence that could be placed upon the *x*-rays in this connection and related cases in which operation was abstained from on account of failure to demonstrate the presence of a suspected calculus with the aid of the *x*-ray. Dr. Clarence Edward Skinner of New Haven read a paper entitled "Two Cases of Severe *X*-ray Necrosis Presenting Some Unusual Features." Dr. Miran K. Kassabian of Philadelphia read a paper entitled "How to Obtain an Instantaneous Skiagraph of the Thorax." He pointed out that the time of exposure for making skiagrams of the lungs and the heart has been reduced to a few seconds, and he predicted their production so rapidly as to demonstrate the movement of these and other viscera in kinetographic reproductions. The advance has been due to improvements in apparatus and increased skill as the result of experience. Dr. Henry Hulst of Grand Rapids read a paper entitled "Skiagraphy of the Chest. Its Why and How." He pointed out the utility of this procedure as an adjunct to other methods of physical diagnosis, and its usefulness especially in the recognition of the early stages of pulmonary tuberculosis. Dr. William S. Newcomet of Philadelphia read a paper entitled "Pathologic Changes in Tissue under the Influence of the *X*-ray." Dr. William M. Sweet of Philadelphia, paper on "Localization of Foreign Bodies by the Röntgen Ray," and Dr. Henry Waite, one upon the "Care of the Static Machine." In the evening the President, Dr. Arthur W. Goodspeed of Philadelphia, delivered an address entitled "The Trend of Modern Thought upon the Subatomic Structures of Matter." On the second day, Dr. Henry K. Pancoast of Philadelphia read a paper upon the "Therapeutic Effects of the *X*-rays as Shown by the Results of Treatment in One Hundred Cases." He related a number of instances in which carcinomatous growths disappeared under treatment. The results were less successful in cases of sarcoma. Lupus, also, has proved amenable to the influence of the *x*-ray. Dr. John T. Pitkin of Buffalo read a paper on "Dangers to the *X*-ray Operator." Dr. Russell H. Boggs of Pittsburg read a paper entitled "Accuracy in *X*-ray Diagnosis." He reported a number of instances in which a diagnosis was made with the aid of the *x*-rays when other methods of investigation had failed. Dr. M. A. Wilbert of Philadelphia presented a communication entitled "A Comparative Study of Fractures of the Extremities." Dr. Weston A. Price of Cleveland read a paper upon "The Technique Necessary for Making Good Dental Skiagraphs." Papers were read also by Dr. Preston N. Hickey of Detroit on "The Development of the Skeleton Radiographically Considered"; by Dr. Kennan Dunham of Cincinnati, on "The Effects of *X*-rays upon Lower Animal Life"; by Dr. Gordon D. Burdick of Chicago, on "Developers," and by Dr. H. K. Pancoast of Philadelphia on "Exploding Tubes."

**Pathological Society of Philadelphia.**—At a stated meeting, held December 10, Dr. G. P. Müller presented a specimen of pancreatic calculus. The patient died in a few days after admission into the hospital, and nothing of clinical importance could be elicited. After death, however, the pancreatic duct was found occluded by calculi, and the gland itself was greatly atrophied, the islands of Langerhans being preserved. The concretions contained calcium carbonate. The condition is a rare one, and probably dependent upon an infective process. Dr. Jos. McFarland presented a case of xanthoma tuberosum. The patient was an undeveloped boy, eighteen years old, employed in a knitting mill. The condition had been present for five months, and was particularly marked in the hands, following the flexures and furrows in a striking manner. Lesions were present at the flexures of the elbows, near the axillæ, on the knees, and one on the gums below the lower incisor teeth. A full description was given of the histologic changes in a bit of excised tissue. Drs. W. M. L. Coplin and A. G. Ellis presented a cummunication entitled "Trypanosoma—Specimens of the Trypanosoma Lewisi." They traced the history of the knowledge of this parasite and of the diseases to which it gives rise, particularly in rats, in horses,

and in man, and they exhibited specimens of blood from rats caught at the Philadelphia Hospital in which the trypanosome was present. Dr. R. C. Rosenberger read a paper entitled "The Actual and Comparative Resistance of Acid-fast Bacteria to Various Reagents." Dr. D. J. McCarthy presented a communication entitled "Some Recent Contributions to the Pathological Anatomy of the Peripheral Nervous System." He discussed especially the changes in the cells of the invertebral ganglia in cases of hydrophobia, and compared them with the changes induced by other infections and toxic processes. He took up for consideration the subject of the regeneration of divided nerves, with particular reference to its bearing on the neuron theory. He also mentioned the occurrence of optic neuritis as a complication of diphtheria.

**Philadelphia Pediatric Society.**—At a stated meeting, held December 8, Dr. Ellis E. W. Given showed an infant with congenital hæmatoma of the sternomastoid muscle. Dr. D. J. Milton Miller showed a patient with congenital heart disease. Dr. J. P. Crozier Griffith showed (1) a patient with extreme cretinism; (2) a girl of four years with paralysis of the bladder; (3) a child with infectious neuritis of uncertain origin, with a report of a second case. Dr. D. L. Edsall read a "Report on Intravenous Injections of Collargol in Chorea." Dr. A. P. Francine read a paper on "Diastasis of the Recti Muscles in Rickets."

**Philadelphia County Medical Society.**—At a stated meeting, held December 9, Dr. T. L. Coley read a paper entitled "Diet in Enteric Fever." Dr. Barton C. Hirst read a paper entitled "Practical Lessons from an Experience of More than One Hundred Cases of Eclampsia." Dr. G. Morton Illman presented a "Report of a Case of Hydrophobia with Autopsy." Dr. Alfred Gordon read a paper entitled "Myxœdema Complicated by Diabetes."

**Bill to Suppress Degeneracy.**—The Iowa Society for the Suppression of Disease and Degeneracy has prepared a bill, it is said, to be introduced in the coming Assembly, providing for a physician's certificate of examination before a marriage license can be issued.

**German Physicians So Numerous that Law May Limit Their Number.**—Under special correspondence of the *Chicago Daily News*, dated Berlin, November 27, it is stated that physicians and surgeons have become so numerous in Germany that there is talk of nationalizing the profession, making doctors employees of the government, or limiting their number by law, like drug stores and saloons, according to the population of the community. Meantime a concerted movement has been set afoot for discouraging young men from studying medicine. The physician's calling enjoys unusual high respect in Germany and physicians command a dignified place in society. Largely owing to this fact the ranks of the profession are terribly overcrowded. The number of practitioners increased 12 per cent. in 1901, and another 16 per cent. in 1902, without any corresponding increase in the necessities of the people for medical treatment, or anything approaching it. There are to-day 29,200 doctors in the country, or more than double the number practising in 1876, while the empire's population has multiplied only by a sixth in the same period. The result is that thousands of German physicians are unable to make a decent living. In the most favored localities there is one physician to every 1800 inhabitants, but the proportion is far different in the cities—in Berlin, one to every 766 inhabitants; in Frankfort-on-Main, one to 814; in Breslau, one to 731; and in Munich, one to 608. It has been ascertained that 46 per cent. of the doctors in Berlin have incomes not exceeding $750 a year. About a quarter of these earn annually from $180 to $750. An eighth of the number are in receipt of doubtful incomes, while 5 per cent. have no incomes at all. In contrast to these figures, it is stated that 80 per cent. of the lawyers in Berlin earn over $2,500 a year. The system of free medical treatment maintained by the State contributes to making the lot of the German physician discouraging. He is allowed only a pittance for services rendered at the "Krankenkassen" or free clinics. It was owing to their desperate financial plight that physicians in several populous communities went on strike last summer and autumn, their object being to compel the State to raise the rate of remuneration at the "Krankenkassen," to which the masses and employed classes flock instead of hiring their own doctors.

**Great Increase in Suicides in Chicago.**—According to the report of Coroner Traeger, during the year 459 suicides were reported and investigated. Of these, 239 were of married people. Of 225 suicides who died by poison, 169 ended their lives by taking carbolic acid. Next to self-destruction, railroad accidents claimed the greatest number of victims—359. The greatest number of suicides occurred during September, reaching as high as 46. March is also a bad month for suicides, having a record of 44. The greatest number of deaths reported occurred between the ages of thirty and forty years.

**The Manufacture of Radium.**—Richard Guenther United States Consul-General at Frankfort, referring to the "Radium Industry" already developed in Germany and France, says: "Notwithstanding the difficulty in its production, a radium industry has already developed in Germany and France, and although 1 gram is sold at a little less than $2,000, the manufacturers are said to have orders for several hundred grams. The demand for medical purposes exceeds the supply. Radium possesses all the important qualities of the Röntgen rays, in addition to the invaluable property of being ready for use at any time and furnishing its rays without the employment of apparatus. It has been demonstrated that a small glass tube, not larger than a goose quill, containing a little more than a thousandth part of a gram, is as effective as an expensive and complicated electric apparatus for the treatment of cancer—surpassing the best effects of the Röntgen rays. The ease with which radium can be administered locally, as, for instance, in the nose and throat, is an invaluable advantage."

**New York Prisons Condemned.**—According to the *New York Times*, John P. Jaeckel, as President of the State Prison Commission, strongly condemned in his report to the Commission—which has recently been sitting in Albany—the city workhouse and the county penitentiary on Blackwell's Island and the condition of Sing Sing prison. His report on the Tombs prison, with the exception of the women's section in the old part, was most favorable. "Sing Sing," he said, "has been occupied eighty years. It is, therefore, plain that it has outlived its usefulness. It is an axiom that the State of New York has failed to keep pace with the advanced demands of public sentiment in the housing of its criminal classes, and has, no doubt, through a narrow and false sense of economy, tolerated a dangerous condition by continuing in service this old obsolete and inhuman receptacle in which human beings are cast to acquire disease and stimulate criminal tendencies."

**General Miles on the Liquor Feature of the Canteen.**—General Miles, talking of the canteen, recently declared that the army posts were very much better

without it. That element discarded, it would be an injury and a step backward to reintroduce it. He went on to say, "I have visited many posts the last year, and I know the conditions are better now than ever before. At one large post in the West the canteen is so well conducted that it has paid dividends of $1 a month to every man, showing that the canteen can be sustained without the liquor feature. There is no more reason for the saloon at any army post than at any well-conducted college or university."

**Red Cross Society to Aid Butler.**—Clara Barton has offered the assistance of the Red Cross to help in fighting the typhoid epidemic at Butler. A lodging house, with twenty-six bedrooms and a large storeroom in the same block, on Negley Avenue, have been offered for the Red Cross.

**Annual Report of the New York Association for Improving the Condition of the Poor.**—This report, which has just been published, shows that the association's work is constantly increasing in efficiency. A prominent feature in the work of the past year has been the care of the foundlings. The report says that under the old system, by which all foundlings were sent to the City Hospital on Randall's Island, ninety-five out of every hundred died before reaching two years of age. Under the present system, by which the association shares responsibility for their care, only twelve out of a hundred die. The report, likewise, says that the death rate among its foundlings is only 11 per cent., while that of all children in the city is 13 per cent.

**Yellow Fever in Mexico.**—It has been reported from Austin, Tex., that no new cases of yellow fever have appeared at Monterey, Tampico, and other places in Mexico for some days. Dr. Eduardo Liceaga, president of the Superior Board of Health of Mexico, has requested the Mexican Congress to make an appropriation of $100,000, to be used in combating yellow fever on the Gulf Coast of Mexico next season.

**Reports of St. Vincent de Paul Work.**—The annual meeting of the Society of St. Vincent de Paul was held on Sunday night, December 13. The reports read showed that during the year the 1,049 members of the society in the Boroughs of Manhattan and the Bronx, divided into seventy parish conferences, had made 45,578 home visits to the poor, and had given relief to 5,892 families, consisting of 21,279 persons, the total cash expenditures amounting to $62,434. The Fresh Air Committee reported the purchase of a fresh air home at Spring Valley, N. Y., where 1,200 children received a two-weeks' free outing during the season. The total expenditure for the fresh-air work during the year were $26,177.92. Reports were also received for the seventeen boys' clubs under the care of the society in the Borough of Manhattan. The Catholic Home Bureau for placing out dependent orphan children in homes reported that 252 children had been placed in good homes during the year, and that the 497 other children previously placed had each been visited by the agents of the bureau at least twice during the year.

**Diphtheria at Harvard.**—There have been six cases of diphtheria recently at Harvard University, all of which have occurred in the Mount Auburn Street district. It is denied emphatically, however, that there is any epidemic. Dr. Bailey, the college physician, believing that in each instance the disease has been contracted in Boston. One of the cases, that of a freshman, resulted fatally.

**Diphtheria at Elmira College.**—Elmira College has been closed for the holiday vacation, two days earlier than had been planned, owing to the fact that one of the students developed diphtheria.

**The Phipps Institute Lectures.**—The third lecture in the course established by the Henry Phipps Institute will be given in the auditorium of the Witherspoon Hall on Tuesday, December 29, at 8.30 o'clock P.M., by Dr. G. Sims Woodhead, Professor of Pathology at Cambridge University, England. The subject of the lecture will be "The Paths of Infection in Tuberculosis."

**Lectures on Alcohol and Opium Inebriety.**—Dr. T. D. Crothers of Hartford, Conn., professor of mental and nervous diseases at the New York School of Clinical Medicine, will deliver a course of four lectures on "Inebriety from Alcohol, Opium, and Other Narcotics," January 5 and 6, 1904, at 4 P.M. and 8 P.M., in the hall of this school, 328 West Forty-second street, New York City. The public are cordially invited to attend.

**A Crusade against Rats.**—An engineer of Copenhagen has organized an "International Association for the Diffusion of Information Regarding Injuries Caused by Rats," the object being to demonstrate the necessity of concerted action looking to the extermination of rats. Last year, by private subscription and public appropriation, a systematic campaign was carried on in Copenhagen and Fredericksberg. A bounty of three cents each was offered for dead rats delivered to the fire-engine houses. The campaign lasted from August 3 to December 9, and 103,786 of the rodents were killed. The Asiatic brown rat is, however, so migratory in his habits that it is scarcely worth while to wage a local campaign, and it is only by a general warfare that a considerable diminution in the number of rats can be brought about.

**First Aid by Railway Employees.**—The trainmen of the Chicago and Eastern Illinois road are to be given a course of instruction regarding the best method of giving aid to the injured in case of railway wrecks. The plan is to establish schools in the various division headquarters and require the trainmen to attend the lectures and demonstrations which will be given on the subject.

**Alcohol as a Medicine.**—At a recent meeting of the W. C. T. U. in Youngstown, Ohio, a resolution was passed appealing to the physicians of the city not to prescribe whiskey or brandy for their patients under any circumstances.

**Good Samaritan Hospital of Cincinnati.**—An annex to the Good Samaritan Hospital, located on Clifton Avenue, Cincinnati, was formally opened last week by a reception to the physicians of the city. The annex is more or less independent of the main hospital, and is open to receive the patients of any physician, whether a member of the hospital staff or not, who may continue to treat them while in the annex.

**Washington University, St. Louis.**—Dr. H. McC. Johnson has been appointed Clinical Professor of Genito-urinary Surgery, and Dr. E. C. Burnett, Clinical Professor of Genito-urinary Diseases in the Medical Department of Washington University, St. Louis. These appointments are made to fill the vacancy caused by the death of Dr. John P. Bryson.

**The St. Louis Medical Society** adopted a new constitution and by-laws on December 12 bringing these more in conformity with the constitution and by-laws of the American Medical Association.

**The American Association of Obstetricians and Gynecologists** will meet in St. Louis in September, 1904. Dr. Walter B. Dorsett of St. Louis is the president-elect. Dr. Potter retains the secretaryship.

**The Model Hospital** in which the sick and wounded will be cared for on the World's Fair grounds during the St. Louis Exposition, is practically finished, and will be dedicated in a few days. The building is 108x109 feet, and contains besides operating rooms, a dormitory for the matron and nurses.

**Officers of the Orleans Parish Medical Society.**—At the regular annual election of the Orleans Parish, La., Medical Society, held December 12, 1903, the following were elected for 1904: *President*, Dr. M. J. Magruder; *First Vice-President*, Dr. J. A. Storck; *Second Vice-President*, Dr. Wm. M. Perkins; *Third Vice-President*, Dr. O. Joachim; *Secretary*, Dr. S. M. D. Clark; *Treasurer*, Dr. E. J. Huhner; *Librarian*, Dr. Homer Dupuy; *Additional Members Board of Directors*, Drs. E. J. Graner, E. H. Walet, and M. M. Lowe.

**Coeducation at Munich.**—The United States Consul-General at Munich states that the Bavarian Minister of Cultus has opened the doors of the University of Munich to women on the same terms as for male students. For the present it limits its admission of women by regular matriculation to such as possess the "abituria" of a German gymnasium. American women, graduates of recognized colleges, but not possessing the gymnasial abituria, are admitted only as hearers, and although with the consent of the faculty they may pursue a regular course of study and finally come up for a degree, they have not the rights of the German students. It is hoped, however, that the authorities will eventually concede to American woman students the same advantages that are now offered to men who are graduates of recognized colleges in this country.

**Dr. Finsen Seriously Ill.**—It is announced from Copenhagen that Dr. Finsen of that city, to whom the Nobel Medical Prize was awarded recently, is seriously ill.

**An Epidemic of Measles.**—Several hundred cases of measles were reported last week at Plymouth, a mining town near Wilkesbarre, Pa.

**Marmorek's Tuberculosis Serum.**—At a recent meeting of the Paris Academy of Medicine an adverse report was presented on the consumption serum prepared by Professor Marmorek. Drs. Dieulafoy and Le Dentu stated that they had had under observation seven patients with pulmonary tuberculosis treated personally by Marmorek, and of these seven five had since died, the remaining two being unimproved.

**Obituary Notes.**—Dr. ELISHA H. BRIDGES died at Ogdensburg, N. Y., December 9, of acute nephritis. He was a member of the Medical Society of the State of New York, the St. Lawrence County Medical Society, and the Ogdensburg Medical Society. At a meeting of the latter organization, the following resolutions of respect and condolence were adopted:

"Dr. Elisha H. Bridges was one of the earliest members of the Ogdensburg Medical Society, having been associated with it since its foundation in the early sixties.

"He brought to the practice of medicine an unusually vigorous and active intellect and an unswerving devotion to his life's work, which he considered the grandest and noblest of all professions.

"His kindliness toward the younger members of the profession and readiness to aid by counsel and example especially endeared him to them. The profession in general always benefited by his thorough knowledge of medicine, quickness of perception, and lucidness of description.

"*Resolved*, That in the death of Dr. Bridges, this society and our profession of medicine have lost one of their most brilliant and honored members.

"*Resolved*, That we extend to his family our profound sympathy in this, their hour of bereavement. —W. Grant Cooper, Willard N. Bell, Walter L. Ryan, Committee."

Dr. EDWARD FRIDENBERG died of apoplexy on December 9, at his residence, 242 Lexington Avenue, in this city, at the age of forty-eight years, having been born here in 1855. He was graduated from the College of Physicians and Surgeons in 1878, and was for some considerable time house physician at the Charity Hospital, and also served as one of the medical staff of Mount Sinai Hospital. He was a member of the State and county medical societies, president of the Harlem Medical Society and a member of the Alumni Association of Mount Sinai Hospital. At a meeting of the latter society the following minute was adopted:

"Our honored president and companion, Dr. Edward Fridenberg, has passed from among us in the fulness of life and activity. We recall with pride the fame he had achieved in the practice of his profession, and the esteem in which he was held by his patients. We recall his unusual kindness, his generous courtesy, his sweet companionship, his broad fairmindedness, his remarkable breadth of character, his great love of humanity, and above all, his great love for children. His culture and his love of the beautiful dominated his life and thought. His qualities made his life an example which we shall always cherish.

"A copy of this shall be sent to the family and to each of the New York City medical papers.

"SAMUEL M. BRICKNER, M.D.
"EDWIN STERNBERGER, M.D.
"WILLIAM H. LUCKETT, M.D."

Dr. CORNELIUS N. O'LEARY of 560 West One Hundred and Thirty-third street was killed by a motor train at New Utrecht Avenue and Fifty-seventh Street, Brooklyn, on Saturday night, December 12. He was removed, on the following day, to the O'Leary residence, where the funeral services were held on December 14. Dr. O'Leary was born in Ireland, and at the time of his death was sixty-four years of age. After having graduated from the College of Montreal, he attended the University of the City of New York, and graduated from the medical department in 1862. Upon the death of his father in 1864 he succeeded him as professor of philosophy and classics at Manhattan College. In 1870 he was connected with the Board of Health in the capacity of inspector, and resigned that position to become a commissioner of pharmacy. Dr. O'Leary was a writer of some note.

Dr. WILLIAM H. HOLMES of Orange, N. J., died at his home in that city on November 30, at the age of sixty-nine years. He was a graduate of the College of Physicians and Surgeons in the class of 1857, and had practised in Orange for nearly forty years. During the Civil War he served as assistant surgeon in the navy.

Dr. JOSEPH M. HARCOURT died at his home in Brooklyn on November 30, at the age of eighty years. He was born in Ireland, but came to this country over fifty years ago. He was a graduate of the New York University Medical School in the class of 1874.

Dr. ISRAEL B. WASHBURN of Renssalaer, Ind., died in Valparaiso on December 11. He was a graduate of Rush Medical College in the class of 1861, and served as surgeon in the army during the Civil War. Two years ago he was operated upon for gallstones, in Chicago, but the results were unsatisfactory, and another operation was decided upon. This was done, and upon opening the abdomen the operator discovered, near the liver, a forceps, about five inches in length, which had been overlooked during the toilet of the peritoneum after the former operation. Dr. Washburn died a few hours after the second operation.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

MEDICAL COUNCIL—COLLEGE OF SURGEONS—EPSOM COLLEGE—OOPHORECTOMY FOR PAIN—COMA IN MEASLES—PERNICIOUS ANÆMIA—SPEED OF NERVE IMPULSES—GUY'S HOSPITAL—INCURABLES—CHARITY ORGANIZATION—MR. ABBOTT'S RESIGNATION—ANTIVIVISECTION RESULT—OBITUARY NOTES.

LONDON, November 27, 1903.

THE General Medical Council met on Tuesday and is still sitting. The proceedings so far are not likely to interest you much. The president opened with another of his lengthy statements of what has passed since the last meeting and what is to be done at this. Most of the past occurrences are familiar to all, and those of chief interest I have told you about at the time they happened.

The Dublin Apothecaries' Hall proposes to resume the preliminary examinations it formerly held. The secretary of that body has asked the Council to pay the travelling expenses of its inspectors, but as the act directs the corporations to pay, the Hall will ask in vain for such relief. The president thought that perhaps an inspection might be less frequent than heretofore.

The two royal colleges decline a conference with the Council on their differences. On the invitation of the Board of Education, Sir J. Tuke and Dr. MacAlister were appointed to represent the Council at a conference on the question of "leaving examinations" at schools taking the place of many preliminary examinations.

The Friendly Societies' Alliance has intimated an intention to oppose the Council's Disciplinary bill in Parliament. The Pharmaceutical Society's bill will contain a clause protecting all existing rights of medical practitioners. The subject of death certificates has to be more fully considered, and the Council will press the importance of the subject on the government. Besides all these matters, the finances of the Council have to be discussed, and the judicial duties which have already consumed much of the time of the session must be completed.

The annual meeting of the fellows and members of the Royal College of Surgeons was held on Thursday. The resolutions were passed, and will no doubt prove as useless as heretofore. This conviction is probably the reason that so few members attend to reiterate their claims. At one time the discussions were so uninteresting that many left the room, and some had to be sought for in the corridors and asked to come back to keep a quorum.

Yesterday Lord Roseberry presided over a meeting of the Governors of the Royal Medical Benevolent College, at which it was resolved to change the name of the institution to "Epsom College." The school has long been popularly known by the short title, now made the legal appellation. It has been felt that the word "benevolent" was a distinct disadvantage and really meaningless for a great school such as Eton, Harrow, and others, and which accommodates 500 boys with fifty foundation scholarships for sons of medical men. Lord Roseberry, as president, takes great interest in the school, and very strongly recommended the change. He wondered that the college had prospered so well under such a name. It was as absurd as it would be to add the adjectives to Eton, which had seventy foundation scholars. Having dropped the encumbrance, he prophesied that the change would mark a new era of prosperity and he knew Epsom College deserved it.

The epidiascope is being freely used for demonstrations at societies. Some instances I have already mentioned at the last meeting of the Gynæcological Society, the president (Dr. Heywood Smith) showed with it a section of a large fibroid tumor in a state of calcareous degeneration from a sterile married woman, still menstruating, though fifty years old. The tumor was so permeated with calcareous matter that there was considerable difficulty in making sections.

Dr. Bedford Fenwick, by the same means, demonstrated sections of ovaries removed from a young woman for pain persisting for ten years in both ovarian regions. She made no other complaint, but there was loss of weight, increased weakness, frequent sleepless nights. She was carefully observed for five weeks in the hospital. Then, as a last resource, Dr. Fenwick did laparotomy. Both ovaries seemed scarcely enlarged. The left had some adhesions round it, the right was quite free. To operator and to Dr. Stevens, who assisted him, they were healthy to all outward appearance. But remembering her ten years' suffering and the results of some half dozen other cases, Dr. Fenwick removed both. From the second day after, she has been free from pain and rapidly gained flesh. The sections of these healthy looking ovaries showed that they were literally riddled with cysts, so that little ovarian tissue remained. Moreover the stroma and capsule appear condensed and thickened.

The question of removing ovaries for the one symptom of pain naturally arises. Out of hundreds of cases of severe pain Dr. Fenwick said he had only had the courage to remove five or six ovaries, but in all these cases which were extreme ones marked thickening of the capsule and cystic degeneration were found. In every one the pain was relieved permanently. In one the patient was also cured of maniacal attacks brought on by her pain.

Dr. Parsons, Dr. Hodgson, and the president agreed that the operation was justifiable. The first thought the pendulum had swung too far toward conservatism, and sometimes the surgeon held his hand when operation would cure. Dr. Hodgson mentioned a case of cure after seventeen years of acute suffering, though he had been reluctant to operate, as in one case of the kind the pain did not absolutely disappear. The president on this point said pain did in some cases persist, and suggested the inclusion of a nerve in the pedicle might account for it, but he believed the pain generally disappeared after a time.

Dr. Fenwick, in reply, admitted that he had hesitated to bring forward the case, but he agreed that the tendency was now not to operate so often as used to be done. His patient was only twenty-seven. He had watched her in hospital for five weeks before operating. She is now dissatisfied that she had not been operated on earlier.

Coma in the course of measles is certainly rare, and when it occurs is usually fatal. Dr. Newton Pitt communicated a case to the Clinical Society at the last meeting, which ended in recovery. The patient was a young man of nineteen. On the fifth day of his illness he became noisy and violent, on the seventh collapsed and comatose. There was more or less coma for four days, and for months afterward his memory was defective. Dr. Pitt looked upon the case as due to a local encephalitis, which cleared up and left only a temporary amnesia. Out of 200 recorded cases of hemiplegia in children eleven started in measles. Other cases more or less similar were related in the course of the discussion. It would appear that coma occurs more frequently than might be supposed in children but far more rarely in adults. Bronchitis, or other complication, may precede the coma. Sometimes the rash is delayed, or scanty, supporting a popular belief that a full rash is a favorable symptom.

Dr. Wm. Pasteur then related an unusual case of pernicious anæmia in a man of twenty-four years, who had to leave his work three weeks before admission, on account of weakness and breathlessness. Nearly all the characteristic blood changes were absent, but the case ran a rapid course, ending in death in seven weeks. Double hemorrhagic retinitis was noted. Sections of the liver, spleen, and testes gave the Prussian blue reaction, and chemical analysis showed the iron in the liver amounted to six times the average, exceeding that in the spleen.

Dr. W. Hunter said the sudden onset and rapid course with absence of usual blood-changes suggested a septic origin, and Dr. Norman Dalton related a similar case in which he had found a fistula leading from the gums to the palate. Dr. Pasteur replied that he had not detected any septic focus in his case, and based his diagnosis on the liver and spleen changes found after death.

Dr. Alcock read a paper last week before the Royal Society, in which he reported that in a series of experiments as to the time occupied by nervous impulses in traveling between the brain and extremities. The time being measurable, he wished to determine whether the rate differed in tall and short men. He examined some varying from 1758 millimeters to 1930 (say about 5 ft. 4 in. to 6 ft in height) and found the rate in both about seventy yards a second. So he reckoned, in the journey between the brain or toe, the time occupied would show a difference from the $\frac{1}{100}$ to the $\frac{1}{180}$ of a second. From the elbow to the wrist he calculated the difference as $\frac{1}{1000}$ of a second. The experiments were made by Waller's method, and so far support the popular belief that little men exhibit quicker actions than taller men.

A history of Guy's Hospital, well illustrated, has been issued by the managers, which will, perhaps, help their appeal for funds. The extensions are traced from 1724, when Thos. Guy founded it and endowed it with £220,000. The first building cost £18,000. Nearly a century later William Hunt left it £180,000, on condition that the accommodation for patients should be increased. Much of the money was invested in land, and the depreciation of that security is well known. In 1886 a sum of £100,000 was subscribed to tide over the bad times which, it was fondly hoped, would not continue long. In 1895 Mr. Gladstone's appeal was made and led to the Prince of Wales (now King) becoming president. In 1901 a further appeal for £180,000 produced £103,000, and now a still larger sum is required.

The Duke of Connaught presided recently at a dinner in aid of the Hospital and Home for Incurable Chil-

dren. In an eloquent appeal he spoke of the interest of Queen Alexandra in every effort for the relief of suffering, and Her Majesty's intense love of everything affecting the well-being of children. For this institution, continued His Royal Highness, more room, more air, improved nursing are required, and to carry out the new buildings a sum of £12,000 is necessary, of which half has been promised. Before leaving the chair the Duke intimated that £5,400 had been subscribed in the room, leaving only £600 to complete the sum appealed for.

The secretary of the Charity Organization Society (Mr. C. S. Loch) read a paper in which he proposed the establishment of a board which should associate all our charities and supplement, perhaps supplant, the system of outdoor relief. A registrar and inspector of all charitable institutions was suggested to coördinate them and bring about administrative unity. Perhaps Mr. Loch would prefer the appointment thus proposed to the secretaryship of the Charity Organization Society. There was some little discussion of his project chiefly directed to eliciting more definite information. No resolution was passed.

Mr. F. C. Abbott is retiring from the assistant surgeoncy of St. Thomas's Hospital—much to the regret of his colleagues. He suffers from that curious condition called night-blindness, and as that interferes somewhat with the duties of an operator, he thinks it well to give up his post and devote himself to some other branch of surgery. His case cannot but excite sympathy and good wishes for his success in private practice.

Dr. Bayliss intimates that he will devote the £2,000 awarded him as damages to further physiological research in University College. So the antivivisectionists have the satisfaction of endowing their aversion.

Dr. G. E. Yarrow, until recently a deputy-coroner in Middlesex, died on Wednesday. In addition to many medical diplomas, he was a barrister-at-law, and so highly qualified for the coronership and the numerous medical and sanitary offices he had held. He was for many years superintendent of the City Lying-in hospital, surgeon to the Royal Maternity Charity, and to a division of the police. He was a past president of the Society of Medical Officers of Health, a D. P. H., and had been superintendent of the City Road Workhouse, and served on the Holborn Board of Guardians. He contributed to the journals on Midwifery, vaccination, and allied subjects.

Surgeon-Major H. de Tatham, who died on the 25th inst., in his sixtieth year, took his M.R.C.S. in 1865 and M.R.C.P. in 1877. He served in India, and was Examiner in the University of Bombay. He accompanied the Abyssinian Expedition (1867-8), for which he received the medal.

Surgeon-General A. J. Dale, M.R.C.S. (1852), died on the 24th inst., after four years' illness, aged seventy-three. He served in the Afghan war (1879-80) and retired in 1886.

Fleet-Surgeon Gilbert Kirker died in Hasler Hospital on Tuesday. He was one of the staff, and while performing an operation on Friday pricked his finger. Septic poisoning ensued. He was M.D., R.W.I., 1876; M.R.C.S., Eng., 1877 He entered the navy in 1879. Served as surgeon on the *Iris* during the Egyptian war of 1882, and was awarded the medal and the Khedive's bronze star.

Inspector-General Pottinger died on the 16th inst. in his eighty-sixth year. He qualified in 1838 and entered the navy the next year and saw much service in China, was at the capture of Amoy, and later at the bombardment of Bomarsund. He held the China and Baltic medals.

## GONORRHŒA IN WOMEN.

To the Editor of the Medical Record:

Sir: The letter of Dr. G. S. Scott of Lampoc Cal., in the Medical Record of the 21st ult. was very instructive and suggestive. As the doctor wrote, it is a common error to examine the vagina instead of the urethra in looking for gonorrhœa in woman. He stated that at the moment of penetration the male and female urethræ come together, that such contact is unavoidable. Somewhat in confirmation of this, Garrigues, in his late work on the "Science and Art of Obstetrics," makes this surprising statement: "The writer has repeatedly examined women who, although they had been married for years to apparently strong men, presented untorn, strongly resisting hymens. Sometimes there is an abnormal laxity of the urethra, so that the examining finger of the gynecologist and the male organ during copulation find less resistance there than at the entrance of the vagina, the result of which is, that copulation takes place in the urethra and the bladder." The expression, "Where ignorance is bliss 'tis folly to be wise," may have arisen upon such discovery.

It may be that the gonococcus is abundant in its normal habitat, like the colon bacillus in its, but does not give trouble except under certain circumstances, and from the fact that it is enclosed in pus and epithelial cells, it is often overlooked. The chemical reaction of the vagina is acid. The micrococcus gonorrhœæ seems to flourish on alkaline surfaces, or such as are approximately such, the urethra, the uterus, the Fallopian tubes, and the eye usually bearing the brunt.

In proportion to the number of exposures to the virus—for to the woman it is like a virus—on the part of the male, is the likelihood of a contraction of gonorrhœa. This accounted for the fact that two men may have intercourse with the same infected woman and one contract a virulent clap, and the other escape. One has intercourse several times with her, while the other only once. Doctor Garrigues' observation reminds us of what was anciently taught concerning the uterus, that it receives the penis.

It is possible that the penis does occasionally enter a subinvoluted uterus, or the uterus whose os is softened by gonorrhœal, or other inflammation.

It may be that this sometimes accounts for the cases of gonorrhœa which are obscure as to origin. Physiologically the os has been seen to open under the influence of the sexual orgasm. The present teaching is that the penis goes up behind the cervix, but its excursions are doubtless aberrant.

Thos. R. Evans, M.D.

Fayette Co., W. Va.

## Progress of Medical Science.

*The Boston Medical and Surgical Journal, Dec. 10, 1903.*

**Albuminuric Retinitis.**—Allen Greenwood declares that it is plain that the prognosis afforded by the discovery of albuminuric retinitis in cases of chronic kidney diseases is very grave, and that life is rarely prolonged more than three years. It has been noticed that cases occurring in the better classes live the longest as a result of better hygienic surroundings and care. The writer believes that as we learn more about the body metabolism in such cases and can give them the best diet, and hygienic treatment, we shall be able to retard the progressive decline and materially lengthen life. How much capsulotomy may do in these cases will be told in the future.

**General Peritonitis Complicating Scarlet Fever.**—John H. McCollom and John Bapst Blake, in their paper on this subject, present the following suggestions concerning treatment: If the signs of peritoneal infection are slight in degree and extent, palliative measures alone, such as enemata, turpentine stupes, and rectal feeding, will suffice. If, however, the pulse steadily rises, and pain, tenderness, and spasm increase, the indication for drainage is imperative. The condition of the kidneys is the most definite contraindication to operation, and whenever possible, cocaine should be substituted for ether. The operation should consist of a rapid cœliotomy, thorough irrigation with hot salt solution, and drainage. Unless there are definite local symptoms the incision should be in the middle line. To favor drainage, hot, moist dressings frequently changed are desirable. Salt solution under the breast and by rectum and water by mouth if the patient is not vomiting are all definitely indicated. Stimulation should be free, but alcohol may be contraindicated by the nephritis. Caffeine, strychnia, and digitalis may be used energetically. The prognosis is always grave.

**Rupture of the Tendon of the Extensor Longus Pollicis; Tendon Transplantation.**—C. L. Scudder and W. E. Paul report the case of a woman who fell in such a way that a blow from a stone step partly severed the extensor longus pollicis tendon without external wound. Three weeks later muscular effort completed the rupture of the tendon with immediate loss of function. The first phalanx could not be extended. If the first phalanx moderately flexed and abducted was grasped by the observer the terminal phalanx could be flexed and feebly extended at will. The metacarpal bone could be extended, abducted, and flexed with nearly normal range. For this patient the extensor longus pollicis subserved almost wholly the function of extension of the first phalanx on the metacarpal bone; and the extensor control of the second phalanx was reinforced by other muscles, probably the abductor and short flexor of the thumb. It is likely that in this patient the brevis functioned chiefly as an abductor of the thumb. This case gives support to the opinion that the extensor longus pollicis is the more important of the extensor muscles of the thumb, and perhaps second to no single muscle of the whole hand in functional value. Moreover, according to the writers, the extensor brevis pollicis acting alone has very feeble extensor control over the first phalanx.

*Journal of the American Medical Association, Dec. 12, 1903.*

**Non-Tuberculous Hemorrhages of the Air Passages.**—L. Page discusses hemorrhages due to acute febrile diseases, hemorrhagic diathesis, syphilis, and local causes, such as

septal conditions, tumors of the nose, pharynx, and larynx. Concerning syphilis he says that in the primary and secondary stages hemorrhages are very rare. In the tertiary and hereditary forms they are much more frequent and are often very severe. It would seem that syphilis would play a most important rôle in the production of hemorrhage from the respiratory tract on account of its predilection for these parts and the destructive changes which are so often wrought here by this disease. It seems that the ulcerative processes rarely invade the blood vessels in syphilis.

**Two Cases of Paratyphoid Infection: One Caused by an Aberrant Organism.**—The cases are reported by G. B. Smith. The first case was that of a man aged fifty-eight years, with a moderate fever, frontal headache, abdominal pain and tenderness; no rash. On the ninth day of treatment he had two intestinal hemorrhages. One week later he began to improve, and was discharged two weeks thereafter. At no time was a positive Widal obtained. Various bacteriological tests were made of blood taken from the arm. An organism was isolated, resembling in morphology the B. typhoid. It had no capsule, was not sporogenic, stained unevenly with anilin dyes and was readily decolorized by Gram's method. It was motile, but more sluggish than the B. typhoid. A second case is also referred to with the isolation of a bacillus resembling that from the first case, but presenting certain differences in reaction.

**The Limitations in the Use of Aconite and Veratrum Viride.**—W. B. Hill states that the primary action of these remedies is stimulation of the peripheral nerve endings; causing a tingling sensation, produced either locally or systemically; stimulation of the vasomotor mechanism, resulting in arterial constriction and slight diuretic effect; powerful stimulation of the respiratory center. The secondary action is paralysis of the over-stimulated peripheral nerves, causing anæsthesia; pronounced depression of the heart, which is augmented by the effect on the vagus; lowering of the bloo-dpressure; and reduction of temperature, which is due at least partly to increased evaporation from its diaphoretic action. The therapeutic indications, then, are to relieve pain, reduce temperature, promote diaphoresis, slow the heart, and reduce blood-pressure; but as the analgesic properties of the aconite are not manifest until after the appearance of the secondary or toxic symptom of the drug, it is a dangerous remedy to use, and we have such remedies as phenacetin, which is more powerful and less dangerous. As a diaphoretic it does not compare with Dover's powders or pilocarpin. As an agent to slow the heart it is far inferior to digitalis, strophanthus or spartein, as they slow the heart by lengthening the diastole, thus favoring the recuperation of that organ. The author does not believe that in our present knowledge of the causation of disease we are justified in using them merely for the reduction of fever.

*Medical News, December* 12, 1903.

**Hysteria.**—William B. Young presents the following summary: We must look to the unconscious impressions of infancy and childhood for the etiology of hysteria. The disease primarily is purely a psychosis. The pathology, the writer believes, is located in the adrenal system. The treatment for hysteria *per se* should be psychical. Suitable resorts should be erected for properly treating and caring for the afflicted among the poor. By such treatment hysteria would soon be on the decrease, instead of on the increase, as it has been for years.

**The Home in Its Relation to the Tuberculosis Problem**—William Osler, in his valuable paper on this subject, states that early recognition of tuberculosis can come only from better methods of practice and greater attention to the art of diagnosis. He sums up the essentials of home treatment of consumption in the small towns, country places, and suburbs of our large cities: First, the confidence of the patient, since confidence breeds hope; secondly, a masterful management on the part of the doctor; thirdly, persistence—benefit is usually a matter of months, complete arrest a matter of years, absolute cure a matter of many years; fourthly, sunshine by day; fresh air night and day; fifthly, rest while there is fever; sixthly, breadstuffs and milk, meat and eggs.

**Some Practical Suggestions on Physical Education in the Public Schools.**—Richard Cole Newton calls attention to the fact that medical inspection should not cease with contagious diseases, but should extend to the examination and record of the physical condition of every scholar. The age, height, weight, and lung capacity, and the condition of the teeth, eyes, ears, method of breathing—whether oral or nasal—should be observed and recorded, and a copy of the record should in every case be sent to the parents and to the family medical adviser. At least once in three months this examination should be repeated and the results carefully recorded and compared with the record of three months before, and these reports should go to the parents just as regularly and faithfully as the reports of scholarship. The writer suggests that a number of teachers of the ornamental and superfluous branches may be dispensed with, and the money now used for their salaries spent in hiring the necessary medical inspectors and in buying more apparatus.

*New York Medical Journal, December* 12, 1903.

**The Administration of Antitoxin in Diphtheria by the Department of Health During 1902.**—J. S. Billings, Jr., gives elaborate tables and presents the following conclusions: There is no longer any doubt as to the curative action of antitoxin in diphtheria. Of 15,792 cases injected with antitoxin furnished free of charge by the department of health or by its inspectors, 1,860 died, a case fatality of 11.8 per cent. If the cases moribund when injected (722 in number) are deducted, the case mortality is further reduced to 7.5 per cent. The one fact, important if not new, brought out in this report is the great advisability—the almost imperative necessity—of the earliest possible administration of antitoxin. Of 1702 cases injected on the first day of the disease, only 85 patients died (including moribund cases), a case mortality of 4.9 per cent.

**Some of the More Infrequent Causes of Obstruction of the Common Bile Duct.**—L. J. Hammond relates a series of case histories which go to show that simple lymphatic infection brought to the lesser peritoneal cavity from organs and tissues remote from it, is a cause of some cases of obstruction of the common bile duct; wherein treatment by cholecystotomy and prolonged drainage are all that is required to bring about perfect recovery. Of course, the obstructive lymphatics, with adhesions caused by the infection, must invariably be removed at the time of operation. We should always expect to find in this type of cases obstruction to the duct of Wirsung, as it is at the junction of the common bile duct with the pancreatic that compression obstruction, due to lymphatic enlargement, has been found. We shall, therefore, meet with many cases in which annoying hemorrhage will accompany jaundice due to pancreatic obstruction, and unless guarded against by preparatory treatment will prove troublesome, if not fatal, at the time of operation.

**A Case of Poisoning by Hyoscine Hydrobromide.**—The patient of F. Krauss was a girl of fifteen years with eye-strain, but no serious changes in the eye-ground. To relax a spasm of accommodation which seemed to be present, the author prescribed a solution of the above-named drug, two grains to the ounce, two drops to be instilled into each eye, twice daily. Only one instillation was made, but four hours later the patient began to talk incoherently, suffered from hallucinations of sight, constantly moved her hands as if picking things up, and threw all the furniture and fittings of her room into the greatest disorder. She continued in this state for about four hours, after which she fell asleep and awoke in a few hours as well as ever. Accommodation was normal three days later. The instillations had been made in the evening, and the author states that the first instillation of a mydriatic for the purpose of refraction should be made during the daytime, preferably the morning, instead of the evening, the time usually selected by our patients. A delirium occurring thus in the middle of the night might readily be followed by some fatal secondary accident.

*American Medicine, December* 12, 1903.

**Infections of the Knee-joint.**—I. R. Trimble reports a few cases of infection of the knee-joint, and declares that a most careful diagnosis should be made in all instances of inflammation in or about the joint. When a purulent inflammation is present in the joint it should be opened early in the disease, and means taken to prevent the formation of pockets of pus. In this manner, both the lives and joints of many patients may be saved. A joint that has been injured and infected is liable like an infected appendix, even if it recovers for the time, to be the seat of future trouble. While it is not possible to remove the source of the trouble, as is done in the case of the appendix, yet, by suitable surgical treatment, the likelihood of recurrence of the trouble may be reduced to a minimum.

**Address on Hernia.**—John B. Deaver states that, from the clinical standpoint, hernia is usually classified as reducible, irreducible, inflamed, obstructed, and strangulated. The exceptions to the radical cure he makes as follows: In children under four, in the hope that time will remedy the defect in the abdominal wall. He believes that the percentage of cures in these children who wear a truss, is perhaps two-fifths. In adults, the subject of serious organic lesions of the heart, lung or kidneys, or in those very fat individuals, in whom the intestine and omentum are adherent to the sac. In adults over sixty,

when the hernia can be held in place by a truss. Irreducible hernia is always to be considered as a dangerous condition, even without symptoms indicating that strangulation has taken place. An incarcerated hernia is also a very dangerous condition. In operating on strangulated hernia the writer performs the radical cure in all cases in which such is practicable. The writer then discusses operations for this trouble from various points of view.

**The Relative Importance to the Community of Pneumonia and Tuberculosis.**—Arnold C. Klebs concludes: (1) That the relative economic importance of pneumonia and tuberculosis cannot be estimated by a mere comparison of total mortality figures for each disease. (2) That the apparently high mortality figure and its increase of late, for pneumonia, is produced by the enormous death rate and its increase attributed to this disease, in early childhood. (3) That, therefore, the high mortality from pneumonia and, to a certain extent, its increase is due to a classification of different ill-defined pathologic conditions under one name, while that from tuberculosis represents that of a well-defined morbid entity. (4) That for this reason, and on account of the relative shortness of disabling sickness and frequent recovery in pneumonia, the great length of disabling sickness and infrequent recovery in tuberculosis, the relative importance of the two diseases is so vastly different that a comparison on economic grounds reveals the overpowering danger from tuberculosis. (5) That the steady decrease of the tuberculosis death rate can be explained on the grounds of increasing improvement of hygienic conditions in late years and as the result of specific prophylactic measures. (6) That the increase of the pneumonia death rate, occurring in a time of improving hygienic and sanitary conditions and of a general application of antiseptic principles, shows its independence of these features. (7) That, therefore, and in view of the still enormous mortality from tuberculosis, its demonstrated preventability and the possibility of its arrest only in its earliest stages, the institution of educational measures in regard to personal and public hygiene widely and specifically applied, for the prevention of this disease, seems to be distinctly indicated. (8) That since for pneumonia, as pointed out by E. F. Wells, "the fundamental information on which prophylactic rules may be formulated is not yet at hand," this subject needs further investigation from a bacteriologic and epidemiologic standpoint as well, before "exaggerated and irrational notions in regard to its dangers and its avoidance" are communicated to the public, which, in view of the facts given, are out of all proportion.

*Deutsche medicinische Wochenschrift, November 26, 1903.*

**The Etiology of Membranous Dysmenorrhœa.**—Gottschalk had occasion to observe a case of this nature for a number of years, and thinks he has discovered the cause of the disease. The various theories which have ascribed it to inflammatory conditions, etc., have not been accepted, but the author has found a condition of widespread venous thrombosis in the vessels of the expelled mucous membrane. This makes its separation by a process of dissecting hemorrhage easy to understand, and the sections sufficiently indicate that the mechanism is analogous to that causing premature expulsion of the placenta. The cardiac weakness causing sluggish circulation is at the bottom of the matter, and the author's case was completely cured by treatment directed to the heart after the usual gynecological methods had failed. That the condition was cured was proved by the occurrence of conception.

**The Treatment of Acute Otitis Media.**—Heine reviews the arguments of the two schools of aurists, one of which, headed by Zaufal, seeks to restrict the performance of paracentesis as much as possible, condemning it as unnecessary and meddlesome, while the other adheres to the views of Körner, and believes paracentesis indicated on the first or second day. The author advocates a middle course, though he considers the operation frequently a life-saving measure, and cites a case terminating fatally in which the patient allowed three weeks to elapse before seeking medical assistance. Paracentesis is to be performed immediately if the presence of retained secretion is suspected, owing to bulging of the drum membrane, and at the same time fever and pain are present. If this triad of symptoms is incomplete each case must be judged on its merits. The patients are put to bed with warm applications, but if the pain becomes severe, sleep is lost, or there is tenderness over the mastoid, the membrane should be punctured.

**The Indications and Results of Talma's Operation for Atrophic Cirrhosis.**—Lenzmann believes that the ascites of cirrhosis is to a large extent due to the cardiac insufficiency rather than to portal obstruction through the new growth of connective tissue. Talma's operation by diminishing the ascites enables the digestive organs to functionate more perfectly, general nutrition is improved, and the heart is strengthened and enabled to maintain the circulation, so that a recurrence of the fluid accumulation is rendered less likely. He reports a case in which the operation combined with fixation of the spleen has apparently effected a complete cure. His indications for the operation are: (1) Cases in which a distinct contraction of the liver has not yet taken place, but evidence of portal congestion, such as ascites, is already present. (2) Cases in which atrophy and ascites are both present, but the absence of extensive loss of liver function may be assumed. Jaundice absent or but slight. Unsuitable cases are those: (1) in which extreme jaundice is present. (2) Cases of urobilin jaundice. (3) Cases in which hemorrhages, delirium, etc., indicate extensive abrogation of the bile-forming function of the liver.

*Berliner klinische Wochenschrift, November 23, 1903.*

**Heroin as Anaphrodisiac.**—Becker has found that heroin has marked anaphrodisiac properties, and recommends its use in such conditions as chordee, satyriasis, and after operative procedures on the penis to avoid erections. In contradistinction to Strauss, who has found the remedy useful as an anodyne in painful affections of the genito-urinary tract, the author does not ascribe any analgesic power to it. The dose must be rather large to produce anaphrodisiac effects; viz., one to two centigrams, but as its effect is a protracted one it can be given with frequent intermissions, thus avoiding the toleration which is apt to result on habituation.

**The Avoidance of Disturbances of Parturition after Vaginifixation.**—Dührssen has observed seventy-nine cases in which no disturbance of pregnancy followed vaginifixation, and believes that such never occur when the operation is performed strictly according to his description. The two points of greatest importance are to perform the fixation high up on the uterus with a single stitch of silkworm gut and to suture the incision in the vesico-uterine fold of peritoneum. Done in this way the operation affords permanent correction of the malposition and may be undertaken in women in the childbearing period without apprehension. Not only do pregnancy and labor proceed to an uncomplicated termination, but previous sterility and habitual abortion observed in a number of the cases reported were relieved by the operation.

**Psychiatry and the Side-chain Theory.**—Alter suggests that Erlich's side-chain theory may be made applicable to the study of certain nervous diseases. Ceni has been able to demonstrate in the blood of epileptics bodies which he calls autocytotoxins, and progressive paralysis also affords a promising field for similar investigations. In epilepsy the course of events is particularly suggestive of the phenomena postulated by the side-chain theory. The specific toxin of the disease is formed within the body from sources still unknown and is set free in the blood. Its tendency, like that of tetanus toxin, is to attack cells of the central nervous system, and having combined with these by means of its haptophore, the toxophore becomes active, the cell protoplasm is attacked and damaged, and an epileptic seizure occurs. The aura represents the incubation period of ordinary infections and corresponds to the time required for the union of haptophore and receptor. During the interval between attacks the haptins are combining with the haptophores and neutralizing the toxin until the latter predominates, when the cells are attacked and another seizure occurs. A somewhat similar line of reasoning may be applied to the phenomena of general paralysis, though the details are still unknown.

*Münchener medicinische Wochenschrift, November 24, 1903.*

**Cow's Milk as Infant's Food.**—Soxhlet rehearses the many difficulties underlying the production of a satisfactory artificial infant's food and points out the great inferiority of even the most carefully prepared substitute as compared with mother's milk. But such careful preparation is impossible in ordinary practice, and the results of carelessness are apt to be serious. The question has heretofore been treated mainly as one of providing a suitable albumen substitute, but it is largely a matter of the fatty constituents. The effort to attribute the superiority of mother's milk to obscure biological features, such as the existence of various ferments, etc., is far-fetched, and the proper composition, cleanliness, etc., of the natural secretion are sufficient to explain its advantages.

**Therapeutic Attempts with Fluorescent Bodies.**—Tappeiner and Jesionek, in a preliminary report, describe very encouraging results in the treatment of lupus, carcinoma, condylomata, and specific primary lesions by means of a

combination of eosin and sunlight. The observations that infusoria were killed by sunlight in the presence of various fluorescent bodies which were harmless in the dark, led to an investigation of the action of these substances on enzymes. The results showed that the specific properties of all the saccharifying and peptonizing enzymes examined were almost or quite destroyed by the combination of sunlight, and even very dilute solutions of fluorescent bodies, while the same agents were without effect in the dark. Different fluorescent bodies were found to possess different degrees of this property; thus cells were acted upon by æridin, eosin, chinolin red, hæmalin, quinine; only esculin was inactive. Toxin was strongly affected by eosin, fluorescin, and magdalared, the others were less effectual. Diastase, papayotin, and invertin were susceptible only to eosin, chinolin red and magdalared. For the therapeutic experiments eosin was chosen as being the most widely applicable, and was painted on the ulcerated areas in 5 per cent. watery solution. At the same time the lesions were exposed to the sunlight as much as possible, and in default of this to the electric arc light. Though no complete cures have yet been attained, the processes of growth were in all instances inhibited and repair begun.

**Estimation of the Pressure in the Right Auricle.**—Gaertner describes a procedure by which the hydrostatic pressure in the right auricle may be simply and accurately measured. If the arm be allowed to hang by the side till the superficial veins are distended, and it is then slowly raised, it will be found that at a certain point, which is constant for every individual, the vessels collapse completely. This point corresponds to the level of the right auricle, and the distended vein furnishes an accurate manometer. Observations on patients showed that any condition causing congestion of the right heart raised the point of collapse considerably, the range of increased height being from nine to thirty-seven centimeters above the normal. The method of making the observations is as follows: The patient should stand erect, or if unable to do this, should sit on the edge of the bed with the feet hanging, and a suitable vein, which is found to collapse readily, should be selected on the hand or forearm. Warm applications or muscular movement serve to make the vessels stand out more prominently. The arm is slightly flexed on the elbow and the upper arm gradually raised from the side of the body, the forearm remaining nearly horizontal, till collapse of the vein is noted. The vertical height of the vein at this moment above the level of the upper border of the fifth rib at its junction with the sternum expressed in centimeters forms a means of indicating the intra-auricular pressure. The degree of congestion can thus be determined and measured for comparison during different stages of the illness and to control the treatment. It also forms a quick and easy method of determining the existence of cardiac or respiratory disease when large numbers of patients have to be examined for this purpose.

*French and Italian Journals.*

**Antituberculous Serum and Vaccine.**—Alexandre Marmorek claims that with his serum he has had cases of undoubted cure of tuberculosis and of laryngitis in the early stages. In osseous, ganglional, and vesicular tuberculosis great improvement has been noted; pleurisy has disappeared under repeated injections—in one case as many as fifty-two were required. In Pott's disease there have been several very successful results, the purulent foci having cicatrized completely. Hectic fever is often allayed by injections of antituberculous vaccine.—*Archives Générales de Médecine*, November 24, 1903.

**The Action of Adrenalin on the Blood.**—M. Loeper and O. Crouzon find that the ingestion or the injection of adrenalin produces certain effects on the blood, some of which are the following: Hyperglycæmia, diminution of the blood ferments, increase and then dimunition of the number of red corpuscles, lowering of the amount of hæmoglobin. The number of the hematoblast is greatly raised; leucocytosis is, as a rule, very marked, especially when Addison's disease is present, or when the capsule has been removed. This leucocytosis is at first polynuclear, but rapidly becomes lymphoid with slight eosinophilia.—*La Tribune Médicale*, November 21, 1903.

**The Elimination of Formaldehyde.**—F. Gianilli concludes from his experimentation on animals that formaldehyde is not found in the expired air, nor in the urine, nor has it been demonstrated in the tissues. He considers the special reaction used by Filippi and Motolese and supposed to demonstrate unmodified formaldehyde in the tissues and in the lachrymal secretion to be non-conclusive, (*a*) because the lachrymal secretion may even normally give a reaction which simulates that of formaldehyde, and (*b*) because the reagents used may give the formaldehyde reaction by its own combinations.—*La Riforma Medica*, November 18, 1903.

**The Interruption of Pregnancy During the Course of Internal Diseases.**—G. Zagari holds that in diseases of the heart it is usually advisable to terminate pregnancy. If there be compensation, a first pregnancy may be allowed to go on, unless symptoms of lack of compensation appear and do not subside. In multiparæ, if life has been threatened in a previous pregnancy, or if a long course of medical treatment has previously been undergone to overcome the cardiac condition, pregnancy must be interrupted. It is also to be terminated in cases of mitral stenosis, myocarditis, fatty degeneration, a complicating nephritis, tuberculosis, grave anæmia and carcinoma.—*Rivista Critica di Clinica Medica*, November 21, 1903.

**Gangrenous Appendicular Abscess.**—P. Bégouin reports two cases of a rather unusual form of abscess of the appendix, in which the walls as well as the contents of the sac are black, and infected—in short, completely gangrenous. This gangrene appears to be secondary, due less to the virulence of microbes than to the organic asthenia of the patient. Both of these patients were over sixty years of age, one was a sufferer from albuminuria, and had had two slight attacks of apoplexy, and the other was extremely delicate and feeble. In the beginning the appendicitis seemed to be of the usual type, and even of a benignant nature. Suddenly pain, fever, and vomiting disappeared, but the patients instead of improving were restless and nervous, complained of extreme weakness, and then passed into stupor. Surgical treatment is of course the only resource, but offers little hope of success.—*Journal de Médecine de Bordeaux*, November 22, 1903.

**The Treatment of False Whooping-cough.**—M. Capitan says that any naso-pharyngo-laryngeal irritation may, in persons with an excitable, nervous system, give rise to a cough identical with that of pertussis. Pharyngolaryngeal grippe and tracheobronchial adenopathy are especially liable to induce this cough. In the former case, in addition to the usual treatment for grippe, give the following powder three times a day: powdered terpene, gr. 0.25; benzoate of soda, 0.25; bromhydrate of quinine, 0.20; antipyrin, 0.25. In addition the throat may be gargled frequently with a ten-per-cent. solution of sodium chlorate. The same treatment will be of service in tracheobronchial adenopathy, but it will be best to give the patient one or two teaspoonfuls a day, in a little beer, of the following: Distilled water, gr. 50.00; iodide of potassium, 2.00; iodine, 0.60.—*La Médecine Moderne*, September 30, 1903.

**The Blind as Masseurs.**—I. Matignon urges the adoption of this vocation by the blind, citing the example of the Japanese, among whom it is practical almost entirely by persons thus afflicted. Sight is not necessary for effectual work in this line, providing the operator be familiar with the muscular system and know the art of massage thoroughly. Sweden, Switzerland, and Belgium are following the example of Japan in this respect, and the author describes a class meeting held in Brussels by Prof. G. Daniel for the instruction of about twelve blind persons. Four theoretical lessons are given at the beginning of the course, as to the value of massage and its application. The fifth lesson is devoted to a study of the skeleton, the sixth and seventh to the muscles which move the various portions of the body. Each pupil palpates the muscles on a human subject. The following lessons concern massage itself, and are continued until the pupils are individually well versed in the art. They are then admitted to practice in the clinics and perfect themselves in the vocation by means of which they are afterward enabled to earn their living.—*Journal de Médecine de Bordeaux*, November 22, 1903.

**The Circulation of the Cephalorachidian Fluid.**—P. Cathelin concludes from his investigations that this fluid has a circulation in the same way as the lymph coming from the blood, and returns to the blood by means of the lymphatic vessels. A schema shows (1) the rich afferent blood vessels to the choroid plexuses, *secretory glands*. (2) The arachnoid sac, canal of discharge and reservoir, but not excretory canal. (3) The perivascular sheaths, falsely called lymphatics, which open into the fluid, and serve as connection between the two circulations. (4) The paravertebral lymphatics and their ganglia, by means of which the profoundly modified cephalorachidian fluid returns to the receptaculum chyli and into the thoracic duct to go with it to the left subclavian vein and the stream of the general circulation, and finally to return to the choroid glands by their afferent vessels. The mechanism consists of many factors—the constant pressure of the fluid, the arterial pulsation of the subarachnoid—pia matrian vessels, the expiratory movements, the different positions taken by the body and weight. This circulation is the slowest of all, but, according to the author, is a well-

authenticated fact.—*La Presse Médicale*, November 11, 1903.

**Typhoid Fever in Nursing Infants.**—René Forget says that the clinical diagnosis of this affection is extremely difficult, the only reliable symptoms being a continued fever, without predominant localization, meningeal symptoms, and slight diarrhœa. If to these signs are added the lenticular rose spots, we may affirm that typhoid is present. Its presence in other members of the family will help clear the diagnosis. The Widal reaction will also be of great assistance. Prognosis is grave, the mortality being about 50 per cent. Treatment consists, in the first place, in diminishing feeding, and giving sweetened boiled water to which some barley water has been added. If there is enteritis, various forms of alimentation will have to be cautiously tried. The fever must be combated by tepid baths of five minutes' duration three or four times a day. Intestinal lavage done very slowly and under slight pressure is the best method for obtaining intestinal antisepsis. Injections of artificial serum may be used to relieve blood-pressure. The mouth, throat, and nostrils and skin are to be kept absolutely clean to avoid secondary infection. Ordinary diet is to be resumed only when there is complete defervescence.—*Journal de Médecine de Paris*, November 22, 1903.

### HEMIPLEGIA WITH APHASIA OCCURRING DURING THE COURSE OF TYPHOID FEVER IN A BOY AGED FIVE YEARS.*

By THEODORE DILLER, M.D.,
PITTSBURG, PA.
NEUROLOGIST TO THE ALLEGHENY GENERAL HOSPITAL; VISITING PHYSICIAN TO THE INSANE DEPARTMENT, ST. FRANCIS HOSPITAL.

A HEALTHY boy of five years developed, about April 1 last, typhoid fever of moderate severity, in which tympanites was a troublesome symptom. On the morning of April 26 (three and one-half weeks after the outset of the fever) the father awakening about 4 o'clock A.M. observed that his son's bed was soiled, being, indeed, in a filthy condition. Taking the boy up to wash him, he noted that he was paralyzed in the right face, arm, and leg, and that he was unable to speak. This condition of aphasia and right hemiplegia, it seems, was almost or quite complete. The boy's intelligence was unclouded. Improvement was soon noted and has continued up to the present time.

In the absence of Dr. McKennan from the city, I saw the little patient with Dr. H. W. Day of Monesson on August 3, some fourteen weeks after the outset of the attack just described. The boy was then able to walk alone unaided, quite readily, although his right leg was markedly spastic and still partly paralyzed. There was a marked degree of paralysis in the right arm, it having recovered less than the leg, and there was also marked spasticity in this member, several fingers being contractured. The facial palsy was not evident. As to the aphasia, the boy had learned to say only a few words. The tendon-jerks on the right side were exaggerated. I was able to note no impairment of his mental faculties aside from that of his speech defect.

That the boy suffered from typhoid fever Dr. Day feels quite confident; and the symptoms noted, together with the fact that the disease was very prevalent in Dr. Day's town, would seem to bear him out in his diagnosis. The attack of April 26 was, it seems to me, clearly one of cerebral apoplexy (whether of embolism, thrombosis or hemorrhage) in which the lesion was so situated as to involve the left internal capsule.

Curshmann[1] says: "Symptoms dependent upon coarse lesions of the cerebral tissue and its vessels are not frequent" (in typhoid fever); and that they usually occur in the later stages of the disease during the decline of the fever or in convalescence They may even occur after convalescence has been established. He has observed hemorrhage, embolism and thrombosis. He mentions two cases of hemiplegia with facial and hypoglossal paralysis; the autopsies showed that one was due to a hemorrhage in the left lenticular nucleus, the other to embolism of the left sylvian artery. He also observed two other cases of hemiplegia with aphasia accompanied by choreiform movements. The lesion in both cases he believed to be due to hemorrhage; but he was uncertain as to whether it was located in the cerebrum or in the meninges. Indeed, Curshmann holds that the differential diagnosis between hemorrhage and embolism in the hemiplegias occurring during typhoid fever is difficult.

Cases of cerebral hemorrhage occurring in typhoid fever have been reported by Griessinger, Jackson, Benedict, Berger, Nothnagel, and Strümpel.[2]

In the case of a young man reported by Osler, convulsions (more severe on the right than the left side) developed on the ninth day of a mild attack of typhoid fever and continued until death ensued, ten hours later. The autopsy revealed thrombosis of the ascending parietal and parietotemporal branches of the middle cerebral artery. In a second case reported by Osler, that of a man aged forty-six a gradual paralysis of the left side developed during the third week of a moderately severe attack of typhoid fever and led to the death of the patient four days later. The autopsy revealed thrombotic softening in the internal capsule. In two other cases of Osler's hemiplegia occurred suddenly during the course of typhoid fever, one of them exhibiting also convulsions. In neither case did death occur; but the recovery from the hemiplegia was only partial.

Welsh[3] has recorded four fatal cases of thrombosis of the middle cerebral arteries.

Hawkins[4] has collected from the literature seventeen cases of hemiplegia which developed in the course of typhoid fever or during convalescence from it. Of these, two were fatal.

Curshmann[5] speaks of aphasia occurring during typhoid fever as an independent affection in a certain number of cases.

*A clinical report read before the Allegheny County (Pa.) Medical Society.

**Occurrence of Epistaxis at the Onset of Acute Rheumatism.**—Hamilton Graham Langwill reports two cases of epistaxis occurring with acute rheumatism—in the second case it occurred at the onset of three separate attacks The author queries whether these instances of epistaxis are, as it were, links to the allied hemorrhagic conditions associated with the rheumatic state described sometimes as purpura rheumatica, the mucous membranes here being the site of the bleeding instead of the cutaneous tissues. Whether or not the condition may have any *prognostic* significance it is impossible to say, from the scantiness of the evidence adduced, but it appeared to the author that the notes of the two cases were sufficiently striking to warrant their publication. Moreover, in view of the increasing body of evidence which is being accumulated in favor of regarding rheumatism as being closely allied to the infective fevers, it is interesting to note this additional point of similarity with such diseases.—*The Scottish Medical and Surgical Journal.*

ALEXANDER LAMBERT, M.D., PRESIDENT.

**Milk in Reference to Infant Feeding.**—Drs. WILLIAM H. PARK and L. EMMETT HOLT were the authors of this paper, which was read by Dr. Park. The object of the paper was to compare the feeding of infants in summer and winter, to note the bacteriological character of the milk, and to determine the importance of the care of the infant as a factor in the results. As a rule, the various groups of children were observed for a period of about ten weeks, and each observer had under his care about fifty children. The bacteriological examinations were made once or twice a week. There were altogether 632 infants under nine months of age. There were 239 varieties of bacteria isolated from the milk, and these were divided into thirty-one classes. These bacteria came chiefly from outside of the udder and the milk ducts. The term "milk bacteria" was found to be very indefinite, and milk carefully protected from contamination was, as a rule, found to contain very few bacteria of any kind. For the most part, specimens of milk from different localities showed differences in the character of the bacteria present. Cleanliness in handling of the milk and the temperature at which the milk was kept were very important factors in determining the character and number of bacteria present in the milk. Cultures of various bacteria from the milk were fed to healthy kittens, but in only one instance was any poisonous effect noted. This, of course, did not prove that the same bacteria might not prove harmful to infants. This failure to discover definite pathogenic bacteria had forced them to rely upon the clinical observations. Most of the children observed lived in the densely populated lower east side of the city. At the outset it was noted that a comparatively small number of the tenement-house children in this district were bottle-fed, a fact which was in striking contrast with the common experience that the dispensaries were crowded with sick children, most of whom were bottle-fed. This seemed to indicate that the breast-fed infants were not often sick. It had been found that, not only in the tenements, but even in institutions for children, it was a common practice, even when care was taken to secure good, pure milk, to add bad cream to it, thus greatly augmenting the bacterial content.

As a result of this investigation, it was found that, in the summer, the store milk gave bad results in 44 per cent., condensed milk in 40 per cent., good bottle milk in 39 per cent., while the best bottled milk gave no bad result. Bad results were noted in 25 per cent. of the breast-fed infants. Practically the same percentages obtained in the winter season. The large percentage of good results in winter from all sorts of feeding was a surprise. In summer the heat and humidity seemed to play the most important part, particularly the former. The general conclusion of those who made these clinical observations was that one of the most important factors in infant feeding was intelligent care. Frequently repeated personal contact with the tenement-house people was essential if much good were to be expected from the distribution of printed directions.

**Effect of Heating Milk.**—To observe the effect of heating the milk, half of the babies were fed after a certain date with the same milk that they had been getting before, with the exception that the milk was raw, while the other half of the number under observation were given the same milk heated as before. The infants were observed carefully for three months. In the first trial, twenty out of twenty-seven infants developed more or less severe diarrhœa within a very short time. Of those on pasteurized milk, 75 per cent. remained well throughout the summer. During the next summer a similar test was made. Of the twenty-four infants, ten took raw milk all summer without bad result. Of those on pasteurized milk, five out of twenty-one had severe diarrhœa. Sixteen out of twenty-one did well throughout the summer. The authors felt justified in the conclusion that during the summer, even when a comparatively good milk was used, there was less sickness when the milk was pasteurized. During the cool weather the death rate and the morbidity among the infants was not appreciably affected by the quality of the milk and the number of contained bacteria. In warm weather the children taking condensed milk and cheap store milk did the worst. The effect of bacterial contamination was very marked when the milk was taken without heating. The number of bacteria which might accumulate before the milk became harmful to the infant depended upon the character of the bacteria, the age of the milk, and the temperature at which the milk was kept. After the first twelve months of life the infants were found to be less affected by the bacterial content of the milk, and when from three to five years old they often seemed to thrive even upon milk containing enormous numbers of bacteria. Of the methods of feeding now in vogue that of milk from central distributing stations unquestionably possessed the greatest advantages; it was a method which deserved to be much more extensively employed, and even carried out by the municipality in the absence of private philanthropy.

Dr. W. P. NORTHRUP emphasized the importance of *intelligent* care as a factor in infant feeding, citing several cases occurring among well-to-do people. Several of these cases were instructive as showing how common it was among the better classes to disturb the children and rack their nerves until they became pitiable examples of true nervous prostration.

Dr. CHARLES G. KERLEY said that he was surprised at the statements made in the paper regarding the large proportion of breast-fed infants in the east-side tenements, because his own records in dispensary work showed that, on an average, about 12 per cent. of the infants under six months old were breast-fed, and after that age most of them were bottle-fed. As a matter of fact, it was impossible to obtain good, safe milk in this city for six or eight cents a quart, and, hence, safe milk was certainly not within the reach of the poor. In a series of 912 infants, treated in the out-patient department of the Babies' Hospital, a little over 3 per cent. died. It was, therefore, possible to obtain good results by properly instructing the mothers. It was his custom to give more dilute food in the hot weather, and to have all of the milk heated almost to the boiling point, or until a film began to form on the surface of the milk. When the mother was not supplied with ice and an ice-box it was necessary to feed the baby on canned condensed milk. It was also useful as a sick diet when used for a short time only. It was a useful stepping-stone between barley gruel and ordinary milk diet. When so used it should be combined with some cereal gruel.

Dr. AUGUST SEIBERT said that in 1888 he had read a paper on the relation between the weather and diarrhœal disease in New York City, giving metereological data for ten years, three observations each day. In this paper 8,036 cases of infantile diarrhœa were studied in dispensary practice. For this period of ten years the mortality statistics of the city were also studied, and it was noted that upward of 32,000 infants died in this time. In his paper he showed that about June 15 in this city gastroenteritis became epidemic every year, and ceased to be epidemic on or about October 15 of each year. This was because on or about June 15 the lowest temperature was at night, and was at 60° F. or higher, and remained at this level until about October 15. The question of humidity had also been considered by him. Heat and humidity acted just as powerfully upon the breast-fed as upon the bottle-fed; the cardinal difference between the

two classes of children was that the one had sterile food and the other had food contaminated with dirt and bacteria. He did not think the problem of infant feeding would be satisfactorily solved until some one found a way of feeding infants with sterile milk—not sterilized or pasteurized milk.

Dr. R. G. FREEMAN said that the results in infants fed on condensed milk tallied well with the experience of many physicians, and showed that the babies fed on condensed milk did about as badly as those fed on store milk teeming with bacteria. Many physicians who formerly employed sterilized or pasteurized milk were now returning to the use of raw milk, and hence, he was glad that the point had been emphasized in the paper of the evening, that, in the summer, infants fed on good raw milk did not do as well as those fed on heated milk. It should be remembered that the sterilization could be effected at a low temperature, one which should not materially change the digestibility of the milk. Commercial cream found in this city was often exceedingly bad, and stale, and this, when added to pure milk, accounted for some of the troubles in infant feeding. Breast milk was often spoken of as sterile milk, but such was not the case; in a considerable proportion bacteria, mostly pyogenic, were found in the milk ducts, and then the the infant received many bacteria from the mother's nipples. Pure pasteurized milk in pint bottles could be obtained from the Strauss laboratory at the rate of six cents per quart.

Dr. WALTER M. SEWARD remarked that a good deal had been said about intelligent care; hence, it was obviously important to give the mothers simple and explicit directions. These he considered more important than the prescribing of medicines.

Dr. PARK, in closing the discussion, said that in winter the bacterial content of the milk in the stores often rose far above that of the milk fed to children in summer, and yet it had been found that many of these children were apparently not harmed by the use of such contaminated milk in winter. The explanation was probably to be found in the lowered resistance of the children during the heated term. He would rather feed an infant on breast milk containing a million bacteria than on cow's milk containing only 20,000 bacteria. The evil effect of hot weather upon infants could not be explained only by its influence in increasing the number of bacteria.

**Cases of Appendicitis with Unusual Symptoms.**—Dr. FREDERICK HOLME WIGGIN presented two specimens of appendicitis. The first one had been removed from a man, about thirty years of age, at the City Hospital, who gave a history of having suffered from attacks of colicky pain in the abdomen, followed by nausea and vomiting for three months past. On examination, his pulse was 104, respirations 28 and temperature 104° F.; the abdomen was distended and he complained of pain on the left, but not on the right, side. Exploratory laparotomy revealed a greatly enlarged, inflamed, and adherent appendix on the left side. The man subsequently developed symptoms of beginning post-operative pneumonia, but these all subsided under the hypodermic use of ergot. The man recovered.

The second case presented symptoms pointing rather to movable kidney, but an inflamed appendix was found and removed.

---

**An Anomalous Case of Myxœdema.**—H. Batty Shaw reports a case in which there were two features of special interest, viz., incomplete effect of thyroid treatment and the occurrence of pigmentation. It is well known that in certain cases of myxœdema, and especially in persons of advanced age, the psychical disturbances are rebellious to thyroid treatment, and the patient gradually passes into a condition of dementia of a melancholic type, and later may develop delusions and die extremely wasted. It might, perhaps, be well in these cases to combine parathyroidal with thyroidal treatment.—*Edinburgh Medical Journal*

ANDREW H. SMITH, M.D., PRESIDENT.

**German Hospital Library Fund.**—The physicians of the German Hospital and Dispensary, having disposed of their library to the Medical Society of the County of Kings, donated to the Academy the proceeds of the sale, three thousand dollars, on the condition that the same shall be known as the German Hospital Dispensary Library Fund.

**The Cleaning of a Great City and the Handling of Its Waste.**—Dr. JOHN MCG. WOODBURY, Commissioner of Street Cleaning, discussed this topic, illustrating his remarks with lantern slides. He first showed the former condition of Hester street and other highways on the east side, with the throngs of people and push-carts which made it utterly impossible to clean those streets. The first step was to restore these streets to the purpose for which they were intended, and this was easily accomplished by moving the fish-mongers to a free market place made for them under the approach to the new Brooklyn Bridge. With regard to the cleaning of the streets, Dr. Woodbury said that the mechanical sweeper would sweep many miles of macadamized streets or thoroughfares in which there was not much traffic, but it could not be used on streets having heavy traffic; in the latter the cleaning must be done personally by the sweeping brigade. There were 1076 miles of streets in this city to be swept once, or sometimes twice, a day. Large portions of the boroughs of Brooklyn and the Bronx were swept by means of the sweeping machines, which, as they worked, were preceded by a sprinkling cart in order to lay the dust. When the temperature was above 45°F., many parts of the city were flushed with a hose. There was no way of cleaning asphalt, removing the gum from it, when the temperature was above 50°, except by the use of the hose. This had been found out by the French many years ago. Even this very day, when the temperature at noon was 38°F., a hose was made use of to wash down some of the streets and remove the snow in the Bowery and various other places on the east side. Sometimes tanks were used in which, by means of compressed air, water was discharged through a hose under a pressure of about 28 atmospheres. The nozzle of this hose discharged the water upon the asphalt pavement at an angle of about 25°, and directed the stream toward the gutter. Another form of wagon was provided with an air compressor, run by a gasoline engine. This would give a pressure of 100 or 120 atmospheres, and would, therefore, clean much more rapidly and efficiently. He had tried various forms of covered carts, but most of them had proved disappointing. The Department had just received three covered carts of a new and very excellent design. The carts have steel covers of the general type of a roll-top desk.

Turning to a consideration of the disposal of refuse, the Commissioner said that the city waste should be divided into four classes: (1) Garbage; (2) ashes, and (3) rubbish. By contract, the garbage was taken to Barren Island reduction works. By garbage was meant swill or kitchen waste. All the garbage was handled by a belt conveyor, and was carried to a series of digesters. In these digesters it was exposed to a temperature of 300°F., and to a steam pressure of 80 or 85 pounds. The digested mass was then subjected to hydraulic pressure. The dried sweepings of the streets constituted the best fertilizer known, and had been used with much satisfaction for this purpose in Central Park and by certain railroads for covering over the sides of cuts and slopes.

A number of photographs were exhibited to show how the shores of Coney Island and other nearby seaside resorts were formerly littered with the rubbish of the city, which had been dumped out to sea. This sea dumping had been entirely stopped since last March. The residuum was very rich in phosphoric acid, and had practically re-

habilitated Central Park. By separating the rubbish from the ashes, the latter became useful for filling in land at Riker's Island. On February 14, 1902, there was a wooden crib around the southwestern part of this island, with water between the drib-line and the island. This had all been filled in with the city ashes, thus actually making sixty-three acres of land. Dr. Woodbury said that when the rubbish was towed to sea and dumped there it cost $300 per week; now, the city rented the privilege of picking over the rubbish on the belt conveyor for $250 per week, and $50 for labor. As the rubbish, which could be sold, produced, when burned, 250 horse-power per hour, it was calculated that there was a gain of about 400 per cent. on the twenty thousand dollars invested in the plant.

### SECTION ON SURGERY.

*Stated Meeting, Held December 4, 1903.*

SAMUEL LLOYD, M.D., CHAIRMAN, PRO TEM.

**Varices with Osseous Deposits.**—Dr. CARL BECK presented a skiagraph of this kind.

**Costal and Thoracic Resection for Pyothorax.**—Dr. CARL BECK read a paper on this subject. He said that if the case were of long duration, or there was evidence of complications, resection of a small piece of rib was insufficient, and a multiple resection was demanded. In 55 per cent. of his cases of pyothorax solid masses were found in the abscess cavity, showing that in these instances, at least, aspiration would have been futile. There was no way of determining the presence of such masses except by making a free opening, and when this had been done there was no reason why the masses should not be removed. Aspiration should be reserved for exploratory purposes, when the patient was extremely exhausted or when the thoracic effusion was of the serous type. The suction method had many and great disadvantages, and should be reserved for temporary use in cases in which the patient was greatly debilitated. Modern surgery required that the opening into an abscess cavity should be made as broad as possible, and that the cavity should be so exposed that its walls could be inspected and palpated, and, if need be, the lining membrane removed. He saw no reason why a pyothorax should be treated on different principles from those laid down for abscesses elsewhere. Never in children, and seldom in adults, were the intercostal spaces sufficiently wide apart to permit of the introduction of the palpating finger. The operation of rib resection was not at all difficult, and, as a matter of fact, the intercostal artery was more often injured in connection with the operation of simple incision than in rib resection, for in the latter operation cutting instruments were not employed after the periosteum had been reached. In the majority of cases the ribs came together after simple incision, thus putting an end to drainage. There were no contraindications to rib resection in cases of old pyothorax. In old cases with the patient in bad condition, a preliminary operation might be done, and the resection postponed until the following day. Cures were sometimes effected in cases appearing most desperate. In view of the absolute hopelessness of tuberculous pyothorax if left alone, rib resection was not only justifiable but absolutely demanded. The surgeon would be on the safe side if he operated upon all purulent accumulations in the thoracic cavity, whether tuberculous or not. Schede's principle that the thickened and almost osseous pleura should be removed was undeniably correct; nevertheless in practice the operation was a most formidable and bloody one. The probe was an altogether unreliable instrument in determining the topography of the thoracic cavity. In 1894, the speaker said, he had first made use of exploratory resection. The rule should be to resect the rib lying approximately in the middle of the roof of the cavity. No particular attention should be paid to the shape of the flap, as this must depend more or less upon the particular shape of the cavity. Having determined the location of the thin portion, where the pulmonary pleura joined, it was then possible to finish the dissection with blunt instruments. Great credit was due to Fowler for the ingenuity of his procedure, nevertheless in most cases resection of the chest wall must be added. Only when the cavity was of small extent would he allow full surgical anæsthesia in these operations. He preferred to operate by the method of Schleich, employing cocaine before the puncture. He did not like the use of either chloroform or ether anæsthesia in these cases. Immediately after the operation the cavity should be tightly packed with iodoform gauze, and later on the packing made more loosely. In the after-treatment stress was laid upon the early use of gymnastics, particularly the use of dumb-bells.

Dr. Beck then presented a little boy who, four years ago, had been operated upon for the first time by another surgeon. The boy improved for a while, but a fistula persisted, and about two years later he had come under Dr. Beck's care. Although four ribs were removed and a portion of the left scapula, together with the costal pleura, there was practically no deformity.

Dr. H. D. COLLINS said that if pus cavities could be treated sufficiently early the more extensive operations described in the paper would not be required. The operation of Schede had always seemed to him too extensive, and the same object had been better accomplished by Dr. Beck. Dr. Collins incidentally referred to a case of extensive pyothorax due to an appendicitis.

Dr. A. A. BERG thought most surgeons would agree with the reader of the paper as to the necessity of primary resection in acute pyothorax, but there were a certain number of early cases which could get along without primary rib resection, and surgeons should not lose sight of this comparatively small number of early cases. He thought the pathology of acute pyothorax was a little different from that of abscess cavities in the soft parts. An acute pyothorax in the early stage was not truly an abscess cavity in every instance. The pleural cavity might contain pus and yet not be converted into an abscess cavity, and the same was true of the peritoneal cavity. Surgeons knew very well that the presence of purulent fluid in a serous cavity did not at all mean that there was present there a true abscess formation. Many of these purulent exudates were simply manifestations of a particularly severe pneumonia, either present or past. When it was purely an exudate, aspiration or an intercostal incision would invariably cure the case, just as when a purulent accumulation in the peritoneal cavity was cured without making use of extensive drainage. Even the presence of fibrin did not necessarily mean that extensive drainage was demanded, because it was well known that fibrinous masses in the peritoneal cavity were often absorbed without such interference. Dr. Koplik had told him that since he had resorted to intercostal incision in desperately sick children, such as were seen in his hospital service, he had had much better results than when he had uniformly resorted to rib resection. The speaker said that he personally agreed with Dr. Beck that in most cases rib resection was required. He thought the DeLong operation was ideal when the pyothorax was accessible; on the other hand, if the pyothorax were confined to the apex of the lung, and especially if it were on the left side, this operation did not seem to him appropriate. He had not had the courage to peel away dense masses from the veins about the neck. For such cases the old Estlander operation was preferable.

Dr. JOHN F. ERDMANN said that it was not his habit in children to excise a rib at the primary operation. He usually picked up the skin, and, without anæsthesia, nicked it and plunged sharp-pointed scissors into the pleural cavity, and so secured drainage. After a month or more, during which time the condition of the child improved, he was willing to resort to the more extensive operation if this were required. Very often the second operation

would not be needed. Even when there were large masses of fibrin, the introduction of a small drain would secure complete recovery in a short time. He had never made use of the incision of Schede or Estlander, preferring to use the straight incision down the median line of the axilla, as this greatly diminished the hemorrhage. The DeLong and Fowler operation was certainly a most admirable procedure, and was one which he had employed with great satisfaction. He never made use of anæsthetics for the primary operation in children; for the secondary operation he would use ether in preference to chloroform.

Dr. SAMUEL LLOYD said that for some years past he had been accustomed in the very acute cases to make an incision between the ribs and drain; but the very large majority of the cases seen by the surgeon were already examples of chronic pyothorax, and in such it was better to make the rib resection at once. It should not be forgotten that the lung was held down by adhesions, and would only expand to a limited extent; consequently a cavity remained between the pulmonary and parietal pleuræ and filled up constantly with fluid. Under such circumstances the operation of Estlander, of Schede, or similar procedures, were required. When the parietal pleura had not yet become hard a good deal could be accomplished by deliberately breaking up the adhesions between the pulmonary pleura and the parietal pleura by the finger. The old theory that the lung would collapse when a large opening was made in the chest was now known to be incorrect. It was true just so long as complete anæsthesia was kept up. His custom was to resect the rib, then stop the ether and incise the pleura. The operator then passed the finger in and broke up the adhesions. This gave rise to a cough, and the lung immediately expanded. He believed in this way the necessity for a more radical operation was averted. Operating in this way, it was no longer possible to make use of the long drainage tube and as a substitute the "spool drainage tube" of rubber, with flanges, was devised. He believed when there was a thick pleura and pus was present, the large incision recommended by the reader of the paper was proper. The conservatism practised by the pediatricians would be all right if it were confined to the acute cases.

**New Instruments.**—Dr. FREDERIC GRIFFITH presented several instruments. The first was a mallet. He said that the vibrations produced by surgical mallets, made of various materials, were quite diverse, and after a study of the subject he had come to the conclusion that the best metal for this purpose was aluminum. A wooden mallet, in which the head and handle were of a solid piece, was then presented as an improvement on the ordinary surgical mallet. In appearance it resembled the household potato-masher.

The next device exhibited was a drip-cup and retainer for irrigator tips. It was made of metal, could be readily sterilized, and was a convenient attachment to the irrigator stand. The last instrument shown was a metal hanger for use on glass-shelved instrument cases.

---

**A Simple Method for the Quantitative Determination of Salicylic Acid in the Urine.**—F. Zeigan has devised a method of a color reaction depending on the violet hue of salicylic acid, ferric chloride solutions. Thirty to 50 c.c. of the urine are shaken up with one c.c of dilute sulphuric acid, and 50 to 80 c.c. of ether. The urine is allowed to settle and the ether which now contains the salicylic acid is removed with a pipette and placed in a separating funnel. It is then shaken up with 2 per cent. ferric chloride solution till no further change occurs. The iron solution is placed in a glass vessel having parallel plane sides, while a second similar vessel containing 2 per cent. ferric chloride solution is placed beside it and 1 to 1000 salicylic-acid solution added from a burette till the colors of the two solutions correspond. The number of milligrams of salicylic acid contained in the urine can then be read off directly from the burette.—*Centralblatt für innere Medicin.*

## NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

*Stated Meeting, Held December* 10, 1903.

HENRY HEIMAN, M.D., CHAIRMAN.

**Hypertrophic Cirrhosis of the Liver in a Child of Six Years.**—Dr. SAMUEL M. EVANS reported this case and presented the child. He could find no cause for the cirrhosis so far as the history was concerned, except the use of coffee. There was no history of tuberculosis or of syphilis, but the child was at present on anti-syphilitic treatment. His own opinion was that the cirrhosis was the result of an autointoxication from the intestine.

**Case of Henoch's Purpura, with Necropsy.**—Dr. WILLIAM L. STOWELL reported two such cases. He said that when the hemorrhages chiefly involved the gastrointestinal tract the disorder was spoken of as Henoch's purpura. The first case reported was that of a child of three years, who had frequent and profuse hemorrhages, and died three weeks after coming under observation. The second child was bottle-fed, and was only two weeks old. Bloody stools appeared and lasted for four days, and this was followed by a purpuric eruption. A few weeks later the child became œdematous and died. The diagnosis of dysentery having been made, a bacteriological investigation was conducted by Dr. W. H. Park, who succeeded in positively excluding dysentery. The autopsy showed ecchymotic spots on the pericardium. The heart was normal. The kidneys and spleen were congested. The liver was unusually dark. There were a few small spots of ecchymosis in the stomach and intestine. The lower part of the ileum, as well as the colon and rectum, were especially dark and congested. Goodhardt and J. Lewis Smith had both reported very similar autopsy findings. Many writers on the diseases of children made no mention of this disorder, under this or any other name. At the present time, observers were disposed to believe there was an infectious cause. Da Costa stated that the blood in these cases was alike that of secondary anæmia, but in the last case reported by the speaker the examination of the blood showed it to be normal. These cases were not very common, and there was much confusion in the classification. The microbic theory received some support from a report from Ireland to the effect that a pig and a cow, and two members of the family caring for these animals, were all affected with purpura. Dr. Stowell said he had learned that purpura was comparatively common in swine.

Dr. L. E. LAFETRA said that the second case just reported, was especially interesting, and it seemed to him that it would be hard to differentiate it from those cases in which petechiæ were present in badly nourished children. These petechiæ might occur on almost any part of the body, and sometimes the petechiæ, instead of being very fine, were quite large. In a recent case, seen by him, there was an accumulation of blood looking like a blood clot in the vessels of the subcutaneous tissue. Œdema of the feet occurred quite regularly in these cases. In the case referred to, one of the little masses was excised, and it was thus learned that the blood was fluid, and was confined in a vein. The case was one of marasmus occurring in a breast-fed baby.

Dr HENRY HEIMAN said that examinations of the blood had been made repeatedly by many observers in cases of Henoch's purpura, and the blood had been found perfectly normal. We should, therefore, look either for a microbic origin, or for an anatomical lesion in the blood vessels. There might be, for example, a deficient intima.

Dr. H. KOPLIK remarked that in two of his own cases, and in one reported by Dr. Heiman, repeated blood cultures, made by an acknowledged expert, gave negative results.

Dr. Stowell said he recognized the force of the criticism made by Dr. LaFetra, and perhaps he should have made

it more clear that his case was not one of those in which petechiæ appear in ill-nourished children.

**Symposium on Lobar and Bronchopneumonia in Infants and Children.**—The following papers and discussion constituted this symposium:

**Pathology.**—Dr. DAVID BOVAIRD, Jr. presented the pathology. He said that the pathology of lobar pneumonia in infancy and childhood presented no striking differences from that of later life. There was regularly a red or gray hepatization of one or more lobes of one or both lungs. While there might be shadings of the color of the exposed surface, the section was usually quite uniform, a characteristic which, taken in connection with the granular appearance, was fairly distinctive of the lobar type of inflammation. It was more common in children than in adults to see a partial consolidation of one lobe, or a distinctly lobular type. The amount of pleurisy seen varied greatly; most frequently there was only a haziness or slightly granular appearance of the pleura. Not uncommonly, however, there was a yellowish or greenish plastering over of the pleura. In some cases of lobar pneumonia the infiltration of the lung was so intense and the degeneration so advanced as to give a very granular appearance and a pale yellow color to the cut surface like that seen in a caseous pneumonia in adults. From time to time, small abscesses might be seen in the consolidation of lobar pneumonia, and at times there might be more or less extensive gangrene. In the early stages congestion was marked, and there was much blood in the exudation; later, the blood disappeared and the other elements of the exudate increased. The general connective tissue of the lung was swollen. The most important associated lesions were found in the pericardium, the meninges, and the peritoneum. These were due to general infection with the pneumococcus.

Bronchopneumonia was met with in about 40 per cent. of all the autopsies at the New York Foundling Hospital. In general, three distinct types were recognized, types which represented stages in the development of the process. In all three stages the process was regularly bilateral, and, for the most part, symmetrical. The posterior parts of the lung usually showed more extensive consolidation than the anterior. In the first stage, the beginning bronchopneumonia or capillary bronchitis, there would be found rings of deep congestion, and, on opening the bronchi, the appearances of a bronchitis were present. Microscopical examination would show the smaller bronchi full of an exudation from the walls of the bronchi, and these walls appeared swollen and infiltrated with leucocytes. The air cells immediately about the bronchus were filled with cells exfoliated from the walls, with leucocytes and a very little fibrin. In the second stage, areas of consolidation were scattered throughout the lung, but having between them pulmonary tissue approaching the normal more or less closely. The third stage was that known as pseudo-lobar bronchopneumonia. Here, the previously disseminated areas of consolidation merged into one another, but there was not present the granular appearance found in lobar pneumonia. Owing to the branching of the bronchi the areas presented a more or less stellate arrangement. Frequently the small bronchi broke down, giving rise to abscesses. With a bronchopneumonia involving the greater part of a lobe there was usually some pleurisy. He had been impressed by the frequency with which empyæmia was associated with bronchopneumonia. This was rather in contrast with the findings in later life.

The bacteriology of lobar pneumonia was well established. In about 95 per cent. the pneumococcus was the causative agent, although it might be associated with other microorganisms. Recent investigators found general infection of the blood in an increasingly large proportion of cases. The disease should prabably be regarded as a general infection with a local lesion. In about 50 per cent. of the cases of bronchopneumonia the pneumococcus was the infecting agent. The tendency of the present time seemed to be to diminish the importance of the local lesion and increase the importance of the general infection and the powers of resistance of the infected individual.

**Symptomatology and Diagnosis.**—Dr. WILLIAM P. NORTHRUP discussed this aspect of the subject. He said that a runabout child when stricken with pneumonia would refuse food, look pale and drowsy and would sometimes vomit. Nurslings would cry and cough, and nurse with difficulty because of the nasal obstruction; they would also have fever and vomiting. The onset, therefore, was abrupt. In a few hours the physician would notice evidences of toxæmia; the child would be drowsy, chilly, and irritable at first, but in a short time would be flushed and feverish, with a pulse of 140 and respirations one-third as fast. When the pulse-respiration ratio departed from the normal, one to four, and approximated one to three, one should always look for a lesion in the lungs. Dr. O'Dwyer had first called his attention to the great practical value of this rule, and his own experience had abundantly confirmed this. Soon there would be diminished respiratory murmur over the affected lung, harsh breathing, bronchial voice and breathing, and bronchial whiff. The cough was so inconstant as to be of little value in primary pneumonia of the pneumococcus type. The symptoms of toxæmia were usually proportionate to the amount of consolidation, although there were exceptions to this rule. It must not be forgotten that pneumonia was an acute infectious disease, with its most prominent and characteristic lesion in the lung; also that there was a characteristic bacteriæmia or septicæmia. The primary pneumonias were usually due to the pneumococcus. The stupor was often so deep as to lead to erroneous conclusions. It was not uncommon, too, for the neck of the pneumonia patient to be rather stiff, but both shoulders and arms resisted as well. In meningitis, particularly of the tuberculous variety, the face was described as "mask-like." The disturbed pulse-respiration ratio almost surely pointed to a pulmonary lesion. In nearly all of the cases seen outside of hospital the nurse did not think it worth while to take a baby's respiration-rate. Another confusing, and not uncommon, symptom was a diarrhœa with the discharge of mucous stools. He was inclined to think that this was an eliminative process. He thought that the cerebral and abdominal symptoms were due to the same infection. The most common mistakes in diagnosis were in confounding meningitis and diarrhœa with prostration with pneumonia. Occasionally pneumonia and appendicitis were confounded by very good clinicians, and, at times, it was not easy to differentiate between pneumonia and mastoiditis.

**Treatment.**—Dr. J. E. WINTERS opened the discussion of this topic. He said that the first thing to consider was the individual peculiarity of the little patient; the second consideration always should be the prognosis. Speaking of lobar pneumonia, he said that this disease had, almost without exception, a favorable prognosis in infants and young children; almost every case would recover without treatment. It was highly important, therefore, that there should be no treatment which would disturb the patient. The child should be kept in a warm bed in a room having a temperature of at least 72° F. He based this on the belief that a cold skin meant contraction of the cutaneous vessels, and this, in turn, meant interference with heat elimination and increased work thrown upon the heart and increased congestion of the weakened vessels of the diseased lung. If the body temperature demanded attention the effort should be made to secure free dilatation of the cutaneous vessels. The physiologists told us that about 78 per cent. of the heat loss of the body was by conduction from the cutaneous vessels, and 10 or 20 per cent. by evaporation from the same surface. About 90 per cent., then, of the heat loss was by conduction, radiation, and evaporation from the

cutaneous surface. If, therefore, contraction of the cutaneous vessels were allowed it would interfere with the escape of heat from the body surface. It was also found that whatever contracted the cutaneous vessels, as, for example, the use of cold, caused the internal temperature to rise. This fact should not be lost sight of. The use of cold to the body surface not only caused a rise of the internal temperature, but caused an intense excitement of the nervous system. To unnecessarily excite agitation and resistance on the part of the diseased infant was to interfere very seriously with the recovery of the child. Four-fifths of the heat of the body was produced in the muscles; hence, anything which produced resistance on the part of the child tended to increase the fever. He doubted very much if a physician who attempted to treat sick children by cold applications could keep the confidence of the best families. The child suffering from pneumonia in private practice should be wrapped in flannel and should be placed in a warm room, with the crib in a part of the room where there was no possibility of exposure to a draught. If the child were restless, it should be soothed by small doses of Dover's powder, and by this he did not mean the unauthorized powder sold by druggists under that name, but the powder made according to the original formula of Dr. Dover, *i.e.* opium, ipecac, and sulphate of potassium, and not sugar of milk. The original Dover's powder was an excellent diaphoretic; the modern preparation going under that name, and containing sugar of milk instead of sulphate of potassium, was sickening, constipating, and worthless. Aconite was strongly indicated under the conditions found in the lungs in the early stage of pneumonia. Another method of increasing diaphoresis was by giving full doses of niter—that is, twenty drops every hour to an infant of one year. This would cause free perspiration, which should be kept up for the first three or four days. It was also important not to urge the child to take much food. Milk should not be offered until the child's thirst had been completely satisfied by water. Great care must be taken to keep the stomach and bowels in proper condition; if there were much abdominal distention in a child with pneumonia the little one would almost surely die. Alcohol should be avoided in the early stages, and should be used with caution in the later stages. Children with pneumonia did not die of cardiac failure, as did adults; the cause of death was respiratory, not cardiac failure. In the rare cases in which alcohol was required, as, for example, at the crisis, it should be given in fairly large quantities, preferably by the rectum and with hot water. In bad cases of pneumonia in which there was grave sepsis, oxygen was valuable almost from the beginning; on approaching the crisis it was equal in value to whiskey and strychnine. When demanded, it should not be given for a few minutes at a time, but continuously, if need be, day and night. It would often save children who would die if only given alcohol and strychnine.

Dr. R. G. Freeman thought the diminution of the respiratory murmur as a valuable early sign in pneumonia should be emphasized, and that, at the same time it should be noted that when this occurred later on in the disease it was a most valuable hint of the beginning of a pleuritic exudate, probably an empyema. Another fact needing emphasis was that a pneumonia might run its course not infrequently in early life without any distinct physical signs of that disease, although the vital signs made it very evident as to what was the true nature of the disorder. Sometimes the physical signs would become manifest later on. The treatment of pneumonia in early life was the treatment of the gastrointestinal tract and of the heart. As Dr. Winters had said, abdominal distention was exceedingly grave. Later on, the strengthening of the heart action was important. The use of alcohol should be postponed until the late stages. Nitroglycerin was particularly valuable when the extremities were cold, because of its action in dilating the arterioles. Digitalin was valuable, but because of its irritating action should be given hypodermically. In some cases, when it was almost impossible to give any drug, oxygen would be found of very great value in strengthening the heart.

Dr. C. G. Kerley said that his first step in the treatment of pneumonia in an infant or young child was to establish a sick-room régime. The child should be kept in the crib, and not on the lap, and the temperature of the room should be about 70° F. In the morning and toward evening the child should be removed to another room while the sick-room was aired for half an hour and then warmed to the proper temperature. There should always be a direct communication between the outside air and the sick-room, which was easily secured by means of the "window board." He did not make use of any protective dressings for the chest, such as oil-silk or sheet wadding jackets, because it seemed to him that they made the child uncomfortable and irritable, were certainly unclean, and rendered the little patient sensitive to exposure during convalescence. That pneumonia was a general infectious disease was now generally admitted, and exposure probably played a much less important rôle in its causation than we had been led to believe. The digestive capacity of the child ill with pneumonia was always considerably diminished, and, hence, the strength of the food should be invariably reduced. In runabout children diluted gruels and broths should constitute the diet, and an enema should be given regularly if there were no movement of the bowels after twenty-four hours. The nurse should be instructed to keep the child's feet warm. Much harm might be done by unnecessary drugging. He used drugs and therapeutic measures only when positively indicated. He rarely used digitalis as a heart stimulant unless given hypodermically. Alcohol was given when the powers of assimilation were bad, and as a stimulant when other means of stimulation failed. He used it for as short a period as possible, because, like digitalis, it interfered with the digestive functions. Antipyretic measures were employed only when reduction of the temperature improved the heart action, quieted delirium, and produced sleep, regardless of whether the temperature was 103° or 106° F. In his hands, the cold pack had been a most satisfactory means of reducing the temperature. A large bath towel afforded a convenient means of applying the pack. Dr. Winters objected to the cold pack because it made the child restless; his own reason for employing the cold was that it did just the opposite, *i.e.* it made the child quiet. The body and upper half of the thighs should be included in the pack, the arms and legs being kept out. If the child were entirely wrapped in the pack shock would be produced and the child would be made worse. The pack should be at first at a temperature of 90° or 95° F., and the temperature then reduced to 80°, 70, or 50° F. by the gradual addition of water at the proper temperature. One could soon learn what degree of temperature was indicated for the individual case. Should the temperature of the patient reach 101° F., the pack should be removed and reapplied when necessary. A continuous pack of 70° F. had recently been required in a boy of three years to keep the temperature below 104° F. As soon as the pack became warm the child would himself ask to have the cold water applied to the pack, and when this was done he would fall asleep. The patient should be rolled from side to side and the pack moistened as required, thus avoiding any special disturbance.

In the management of bronchopneumonia, all of these suggestions were appropriate, but in this disease one must use measures which might be considered of a curative nature, for the disease did not terminate by crisis. The first rule should be to keep on good terms with the gastrointestnal tract. The speaker recommended counterirritation to the chest and medicated steam inhalations. The application of a jacket, made of one part mustard and two parts flour, to the skin, keeping it on until the

skin was thoroughly reddened, was often of great service. This should be repeated at intervals of about four hours. It was of special value in the early stage. In the use of steam inhalations of creosote in bronchopneumonia, we had a therapeutic measure that excelled all others. Twenty drops of creosote should be added to one quart of water, and the child should be steamed for thirty minutes at intervals of an hour or an hour and a half. Oxygen was often useful, but it should be given intermittently; its continuous employment had not proved advantageous in his ands. The pneumonia patient should be disturbed as little as possible, particularly at night—a fact which should be borne in mind in arranging the time for applications and medicines.

Dr. H. KOPLIK said that the physician should ever bear in mind that pneumonia was a self-limited disease of an infectious nature; therefore, the nearer the physician approached the work of the skilful nurse, with the brain of the physician, the better. Some cases ran their course insidiously without fever. When Dr. Winters said that cold was very detrimental to children he simply echoed the sentiment of most physicians who had much to do with children. Some patients did very well with a temperature of 104°F., while others did not stand this temperature well, and required some interference. The chief points were the management of the temperature and of the heart, and the avoidance of complications. In the management of the temperature the mainstay of the physician was hydrotherapy, although occasionally a dose of phenacetin and caffeine would prove very beneficial. As a rule, little children did not react well to cold, and he, therefore, could not agree with Dr. Kerley. If a bath were used, the child should be placed in a warm one, and the temperature should rarely be reduced below 80°F., even though frictions were kept up. More commonly a sponge bath with lukewarm bath would be employed. The use of the wet pack at 85°F., or over, was especially useful in cases of bronchopneumonia running a temperature not over 104°F. He was disposed to think that aconite and strychnine would do more harm than good in the hands of the young practitioner in the treatment of infantile pneumonia. He considered alcohol a valuable drug as well as a food in the treatment of pneumonia. Inhalations he never used, because they excluded the fresh air, allowed the air of the room to become full of moisture and excited cough. He objected to poultices because of the weight upon the chest. When a little fluid was found in the chest after a pneumonia had lasted some days the question arose as to whether this fluid should be removed. He usually advised leaving it alone at this stage.

Dr. WILLIAM L. STOWELL said that the same plan of treatment would not work equally well in hospital, dispensary, and private practice. Theoretically, crupous pneumonia should be benefited by steam inhalations. Practically, he found that it was so benefited, and also that bronchopneumonia, was also benefited by such inhalations, although, theoretically, it should not be. Under the necessarily simple and apparently inadequate treatment carried out in the tenement-houses he had obtained just as good a mortality rate as in hospital or private practice under more elaborate methods.

Dr. WALTER LESTER CARR said that frequently in children there was a cough, or at least an expiratory effort, present in pneumonia. In the majority of cases of lobar pneumonia there were gastrointestinal symptoms present. He was glad to note that the consensus of opinion was against the use of cold applications in young children, especially in the form of the plunge. Lobar pneumonia required very little treatment, and in this respect it presented a marked contrast to bronchopneumonia.

Dr. Kerley explained that he did not use any great degree of cold, and that it was always employed cautiously and to meet indications.

Dr. S. H. DESSAU emphasized the point made by Dr. Bovaird, that lobar pneumonia was an infectious disease with a local lesion. He had personally found that a bad or good prognosis could be based upont he greater or lesser amount of albumin present in the urine.

Dr. Winters said that aconite should never be used except in the first twenty-four or forty-eight hours of the disease. It was a very bad practice to make use of strychnia early and throughout the course of pneumonia. It should only be used at the crisis. He had omitted to say that in endeavoring to subdue the nervous excitement of a child suffering from pneumonia and high fever, it was sometimes most useful to apply a long, narrow ice-bag, bandaged in a towel and wrapped around the neck so as to cover the large vessels of this region. This bag should be filled with very finely chopped ice. This method of applying cold was entirely unobjectionable, as it did not interfere with the cutaneous circulation.

Dr. BOVAIRD said that from certain recent experiments, made by Dr. Augustus Wadsworth, the conclusion had been reached that both lobar and bronchopneumonia were infections with the pneumococcus, and that the production of one or the other form depended upon the relation between the virulence of the infecting organism, and the powers of resistance of the animal so inoculated This seemed to indicate that not so much stress should be laid upon the anatomical distinctions between the two forms.

## New Instruments.

### THE TREATMENT OF LACRYMAL STRICTURE.*

NEW METHOD—NEW RESULTS. PRESENTATION OF NEW INSTRUMENTS.

BY J. WILKINSON JERVEY, M.D.,
GREENVILLE, S. C.

THE common occurrence of lacrymal stricture and its attendant inconvenience, and even danger to the ocular integrity, combined with its frequent intractability to treatment, often make this affection a source of great anxiety to the patient as well as to the ophthalmologist. The accepted method of treatment for the last few years has been to split the lower canaliculus almost or quite down to the sac, and then to pass through the split canaliculus, sac, and nasal duct, at intervals of about forty-eight hours, a series of solid probes. These probes, only one passed at one sitting, range in diameter from ½ to 4 mm. An effort is made at each sitting to pass a larger size than that used at the previous visit. Antiseptic syringing and collyria are generally used.

Authorities differ as to the limit of size to which the duct can wisely and safely be probed, and the force to be applied in the attempted passage. Theobald (Norris and Oliver's System of Diseases of the Eye) uses for his largest dilatation a No. 16 probe, 4 mm. in diameter. He says that in using the large sizes of this instrument he occasionally finds it necessary to utilize the strength of both hands in order to effect a passage. The Professor has made his reputation, and is doubtless privileged to exercise certain liberties; but, pray let me counsel those among us who still may aptly style ourselves the Great Unknown, to take no such chances with their reputations or their patients. If you have never attempted this heroic measure, heed me when I cry out, "Don't!" If, on the other hand, in the exuberant enthusiasm of youth you have already transgressed, as I have, my counsel is superfluous, I'm sure.

My experience has taught me that if the luxury

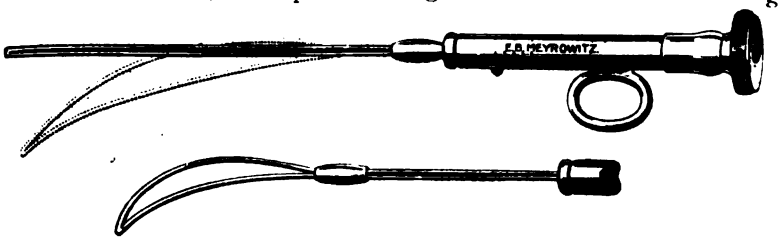
*Read before the Tri-State Medical Society of Georgia, Alabama, and Tennessee, at the meeting in Atlanta, Ga. October 13-15, 1903.

of the apparently triumphant moment of a false passage has been indulged in, the patient may be dismissed at once as incurable. The chances of a cure thereafter are infinitesimal. Thenceforth the length of palliative treatment is to be limited only by the length of the patient's purse and patience.

Some surgeons believe certain strictures to be amenable to cutting, and for this purpose is used a delicate, long-shanked knife. The use of this instrument is preceded by the passage of small probes, and is followed by that of larger ones. When it is necessary to split the canaliculus, the incision should lie well to the inner side of the lid, otherwise a bad cosmetic effect is produced, and, even worse, bad drainage, or none at all, will result.

One of the most objectionable features of lacrymal probes of large calibre, such as Weber's conic probes, and Theobald's high exaggerations of Bowman's, is that necessarily by their use the entrance of the canaliculus into the sac is tremendously dilated. Besides, the splitting of the canaliculus for its entire length is necessary as a preliminary. These conditions are undesirable for two important reasons, first, that capillary suction and drainage are apt to be interfered with; and second, that the large orifice permits easy entrance of foreign matter into the sac. The little instrument here illustrated is designed to remove, at least partially, these objections, and in addition it seems to possess original advantages.

I shall not recite histories; too often their effect is soporific. Let me say, however, that in my own practice this dilator works like a charm. I may seem enthusiastic; doubtless I am. But when, in case after case, an ophthalmologist is enabled



to cure, so far as he can see, in anywhere from two to ten sittings, a distressing affection which he has had dragging along unsatisfactorily for months and even years, some extenuating circumstances must be granted. True, I have had barely four months' observation of the treatment, but thus far it has been all that could be desired and more than might have been expected.

The principle of the instrument is simply that of a wire bent double upon itself. When traction is exerted upon one free end, the other being held firm, a buckling results. This buckling accomplishes the dilation. The instrument can be introduced as easily as a No. 1 or No. 2 lacrymal probe, and when *in situ* can be dilatated to any desired extent, thus avoiding the trauma and irritation necessarily involved in forcing a large solid dilator into the passage. The greatest pressure of dilatation occurs at the point of the greatest resistance in the canal, which, of course, is the location of the stricture. While the instrument is in place and the wires are separated the passage is open for syringing, or even for applications by means of a cotton-tipped probe. This is possible with no other form of dilator hitherto devised. By this means, with every fold and crevice of the mucous lining on the stretcher, the entire surface is accessible to flushing and medication.

With this instrument it is often feasible to dilate lacrymal strictures to any desired extent without splitting the canaliculus. In this way the surgeon can avoid many of those unfortunate cases in which even after the stricture has been relieved by the old method, epiphora persists on account of the lost power of capillary attraction and suction due to splitting of the canaliculus. Were this last the only advantage the dilator possessed it would still be of inestimable value to the ophthalmologist.

The instrument is provided with a sliding collar which can be pushed down to the punctum lacrymale in those cases in which splitting is unnecessary, so preventing the possibility of rupturing the punctum or canaliculus in the process of dilating the remainder of the canal. The wire part of the dilator is slightly malleable and can be bent to any desired curve. The instrument is manufactured by E. B. Meyrowitz, New York. I wish, here, to thank Dr. W. M. Norwood, a dental surgeon of my city, for most important suggestions and material aid in the preparation of the original model.

In using the dilator, I practise the following technique: After instilling adrenalin and cocaine into the eye, the attempt is made to pass through the lower canaliculus a No. 1 or No. 2 Bowman's silver probe. If this cannot be done after repeated trials, the punctum is incised for about 2 mm., and another effort is made to pass the small probe. If this be still impossible, then the canaliculus must be split in the usual way. With a small syringe and silver cannula adrenalin, cocaine, and boric acid, in separate or mixed solution, are injected into the sac and as far down the canal as possible. This has the valuable triple effect of antiseptic flushing, production of anæsthesia, and often enlargement of the lumen of the passage by lessening the mucous vascular engorgement.

After a wait of five minutes for these agents to take effect, the dilator, with a little simple aseptic or antiseptic lubrication, such as carbolated or borated vaselin, is passed through the canal, the way having first been gently explored by the small Bowman probe. The dilator being held by ring and barrel with the left hand, the right hand turns the thumbscrew to spring the wires apart. The amount of dilatation can easily be gauged while the instrument is in position by means of a small scale on the barrel.

The dilatation should be effected slowly, and a little at a time, with waiting intervals between the turns; when it is done slowly and gently, little pain is caused. Having been sprung to the desired extent, the amount of spreading being increased a little at each successive sitting, these being about forty-eight hours apart, the instrument should be allowed to remain in the passage for ten or fifteen minutes, stretching it open. Then the thumbscrew is rapidly reversed, the instrument is withdrawn, and the passage is syringed with some suitable antiseptic solution. In the intervals between sittings, the patient is given the usual antiseptic wash for the eye.

125 South Main Street.

**Tonsillar Hemorrhage.**—Lawrence R. Ryan reports several cases of severe tonsillar hemorrhage, and from his experience he tabulates the plans of operation in the following order as productive of the most danger: (1) Removal by the bistoury, a plan which is almost absolete. (2) Removal by the tonsillotome, which elevates the tonsil. (3) Removal by the flat tonsillotome (McKenzie). (4) Removal by the galvanocautery snare. (5) Removal by the cold snare. (6) Dissection, or tonsillectomy by the galvanocautery knife, requiring several sittings.—*Illinois Medical Journal.*

## A CHEAP AND SERVICEABLE INSUFFLATOR.

By E. J. KEMPF, M.D.,
JASPER, IND.

THE therapeutic value of medicated powders has always been recognized, and their use can be greatly increased if a little common sense be used in the home production of apparatus for the use of the powders.

Take an ounce quinine bottle, perforate the cork in two places, insert glass tubing which can very easily be bent over an alcohol flame, and to the end of the tube which is the longest in the bottle and shortest without, attach an ordinary atomizer bulb that can be bought at any drugstore for twenty-five cents.

The cost of this powder-blower need not be over thirty-five cents and a little labor, and it will be the equal of any powder-blower ever made. I have used it for the last fifteen years with the greatest satisfaction to myself and patients. The article in the MEDICAL RECORD of November 21, 1903, on a new form of insufflator, by Sayer Hasbrouck, M.D., induced me to call the attention of the medical profession to an instrument easily made, and at almost no expense. Try it.

## Medical Items.

**Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending December 12, 1903.:**

| | Cases. | Deaths. |
|---|---|---|
| Measles | 505 | 6 |
| Diphtheria and croup | 428 | 41 |
| Scarlet fever | 249 | 3 |
| Smallpox | 2 | ... |
| Varicella | 106 | ... |
| Tuberculosis | 266 | 166 |
| Typhoid fever | 68 | 15 |
| Cerebrospinal meningitis | ... | 7 |

**A Systemic Affection and Febrile Symptoms with Rontgen Dermatitis.**—Guido Holzknecht denies many symptoms often reputed as following or accompanying the use of Röntgen rays, but states that a definite and clearly defined secondary constitutional illness may follow Röntgen dermatitis. These symptoms do not appear in connection with each attack, but are rare, occurring at the rates of 1 to 1000 or less in cases of this dermatitis. This is the clinical picture. There are evening intermittent fevers, with considerable rise of temperature (30.5° C. or more), appearing, as a rule, when the reaction has reached or passed its height. There are mild chills followed by feelings of heat. The temperature rises to about 39° C., sleeplessness, concentrated urine. Irritating urination appeared in one case. The fever generally lasts a few days or a week, usually stopping when the stage of desquamation or new epidermization begins. In one case it lasted three weeks, but here there were several reactions at different times, and the edges of the patch had long been covered, while the center was still a reddish blue. The appetite remains good, there is no headache, no loss of strength. In a group of five cases there was a universal or a partial exanthema over the body—in form of a small papular dermatitis, crowded in some places, presenting an erythematous surface. The eruption appeared with the first rise of temperature and faded out within a week. It was entirely gone in a few weeks. In two cases it was mistaken for scarlet fever. In one case it was mistaken for septicæmia, with the excoriated Röntgen dermatitis as the point of entrance. The likeness was perfect except for the continued well-being of the patient.—*Archiv für Dermatologie.*

**The Climate Cure in Consumption.**—S. A. Milliken suggests that the medical profession establish a chain of sanatorium settlements extending from the woods of Maine to the deserts of Arizona, from the mountains of New York to the beaches of Florida, from the pine-groves of Washington to the orange groves of Southern California, and from the gulches of Colorado to the plateaus of Oaxaca, with the organization of a corps of student workers whose business it should be to dig and delve, to explore and investigate, to study and experiment, to arrange and classify, to select and digest and to apply for the good of the sufferer the knowledge gained. There should be such arrangements made that each patient could be sent to the place best suited to his needs, and changed from one place to another as necessary. The scheme may sound Utopian, but, according to the author, is perfectly practicable. It should start with the establishment of headquarters at a point deemed most suitable for a receiving and distributing center, with a few tents and cottages at other points offering varied conditions as regards altitude, temperature, humidity, etc., and such provision for attendance that the patient in the remote tent in the mountains should have the same skilled supervision and the same care, in so far as he needed it, as the patient in the home settlement. Extension would follow in time.—*The Alkaloidal Clinic*, November, 1903.

**Pneumothorax in Children.**—David Bovaridi reports two cases of this disease produced by the rupture of areas of bronchopneumonic consolidation occurring as complications of measles; two cases produced by the rupture of small abscesses of the lung, the clinical history of which is not known, and a fifth case, which was probably due to the rupture of an emphysematous vesicle. From the limited number of cases reported in literature, it would appear that pneumothorax in children is most liable to occur in the diseases which are characterized by their tendency to bronchitis, bronchiectasis, and branchopneumonia; namely, measles, diphtheria, and whooping-cough. It occurs also in association with tuberculosis of the lungs, but apparently not with the frequency noted in adult life. As only four of the eighteen cases collected, recovered, pneumothorax in childhood must be considered a very grave complication. Experience is too limited to attempt to formulate any rules for the treatment of the affection, but the extensive displacement noted in one of the writer's cases, and the evidences found of resulting interference with the function of the heart, suggest the advisability of withdrawing the air from the pleura, or, in the event of the failure of this procedure, making a free incision into the pleura.—*Archives of Pediatrics.*

**Chorea; What Is It?**—Charles J. Aldrich divides chorea into two classes: (1) Chorea of Sydenham. (2) Secondary or symptomatic chorea, including (*a*) chronic progressive, or Huntington's chorea; (*b*) prehemiplegic disorders of movement; (*c*) post-hemiplegic disorders of movement; (*d*) congenital chorea, more properly congenital athetosis; (*e*) chronic chorea. A satisfactory presentation of the pathogenesis of chorea in the present state of our knowledge is impossible. It is evident that we have to deal with an abnormally susceptible nervous system and the action of some toxin or toxins which are the result of bacterial infection. The belief is growing that the disease is due to irritation of the motor mechanism, most probably the cells of the cerebral cortex, by some irritant of infectious origin. That individual predisposition usually exists is certain, and that the rheumatic diathesis, particularly when associated with degenerative types and precocious development of the mental and psychical functions must be considered important causative agents, is positive. Indeed, it must be regarded as a disease of neurotic stock, a stock too finely organized to undertake safely the competition, the overwork, anxiety, and successes, as well as the failures of school life; unable to withstand successfully the changes of adolescence as well as early pregnancies—in fact, anything which produces a lowering of the normal physiologic resistance.—*Archives of Pediatrics.*

### MORS OF THE PONTO-MEDULLO-CEREBELLAR SPACE. ACOUSTIC NEUROMATA. CENTRAL NEUROFIBROMATOSIS.)*

By JOSEPH FRAENKEL, M.D.,
AND
J. RAMSAY HUNT, M.D.,
NEW YORK.

DER the above title will be considered a group of es characterized by a local or regional manifestan of neurofibromatosis. This consists in the mation of tumors (single or multiple) on one or re cranial nerves. The acoustic nerve is most quently thus affected and next in order the geminus. How often and to what extent the ner cranial nerves become implicated in the urofibromatous process is not definitely settled.

The pathological occurrences on the cranial rves are identical with those of generalized urofibromatosis of the cerebrospinal and sympaetic nerves. The two types are not infrequently und associated.

One of the first cases belonging to the group der discussion was reported by Foerster[1] in 62. In 1900 Von Monakow[2] reported three es in which the anatomical and clinical peculiares were accurately stated. He called especial tention to the surgical possibilities of the contion. Since then Henneberg and Koch,[3] Hartan[4] and Sternberg[5] have made valuable contribuns to the subject.

The condition is by no means a rare one. The ajority of the recorded cases are found classified der the various headings of intracranial tumors mors of the posterior fossa, tumors of the rebellum, pontine tumors, etc.). Our contribun consists of the report of five cases with autops. Three were cases of tumors of the acoustic; e a case of bilateral tumor of the acoustic, and e a case of tumor of the trigeminus. Four of the es were observed by ourselves and for permission publish the fifth we thank Dr. B. Onuf.

*Etiology.*—The underlying causative factor in all es is a teratological one. The rôle played by umatism, frequently mentioned in the histories these cases, is apparently of no greater importance d is as uncertain as in cases of brain tumor in neral.

*Pathology.*—Regarding the frequency of neuromatous involvement of the cranial nerves, it necessary to emphasize that we consider here rticularly the involvement of the intracranial gment of the respective nerves. The acoustic ows a marked predisposition and is most frelently involved, rather rarely on both sides. e trigeminus is next in order, but rarer. The cial is believed by some to be occasionally the t of these tumors; its proximity to the acoustic rve renders pathological decision difficult.

The neurofibromatous involvement of the other nial nerves, which has been reported, was mostly extradural. It is also to be noted that the neurofibromata found on the other cranial nerves were usually associated with generalized neurofibromatosis, and rarely of clinical significance. The fibromatous growths of the acoustic are of rounded form, varying in size from a cherry to a hen's egg, of fibrous consistency and distinctly encapsulated. The surface is nodular and irregular. Care in the examination will usually demonstrate their attachment to the atrophic nerve trunk. A small remnant of the nerve trunk, a few blood vessels and loose meningeal adhesions form the only connections of the tumor with its surroundings; hence it may be lifted with ease from its attachments, leaving a corresponding excavation in the structures composing the ponto-medullo-cerebellar space.

Sometimes the growth diffuses itself along the acoustic nerve, penetrating the meatus auditorius internus. Histologically these tumors are neurofibromata. Medullated nerve fibers may be demonstrated by the Weigert method in the peripheral and central portions of the tumor. Very commonly, in the more advanced stages, the growth assumes a sarcomatous nature. The cells become enlarged, proliferate and show mitotic changes; increased vascularization with hemorrhages are also observed.

In a limited number of cases glia tissue has been demonstrated in these tumors, and gliosarcomatous degeneration has taken place. Myxomatous and cystic degeneration is also noted.

One of our cases was accompanied by curious changes in the cerebral cortex, consisting of protrusions and minute herniæ, attached to and sometimes perforating the dura. These appeared as minute tufts and excrescences, which, when the dura was stripped off, left depressions with sharply demarcated boundaries. Histologically these herniæ were formed of brain substances, composed largely of ganglion cells of the spindle type and of glia cells. The outer portion is fungoid and structureless. There were no evident vascular or inflammatory changes observed.

Interesting cortical findings in cases of fibromata of the acoustic were reported by Henneberg and Koch. They reported hyperplasia and hypertrophy of the glia cells of the cortex, especially in the deeper layers. In some areas these changes could be observed with low power. Another associated pathological change was found in one case reported by Henneberg and Koch and in one of our cases; namely, endotheliomata and psammomata of the dura mater. Cases are recorded which were complicated by the presence of sarcomatous tumors within the substance of the brain. These changes may all be cited as further evidence of a congenital tendency to teratological conditions.

The point of origin of the tumors under discussion is still an undecided question. The subject is somewhat complicated by the occasional heterogeneous structure of the tumors (fibrosarcomata, gliosarcomata.)

For a short but variable distance, prolongations of the glia accompany the nerve trunks after they pierce the fibrous sheath. This would afford an

*From the Montefiore Home and the Pathological boratory of the Cornell University Medical College. ad before the American Neurological Association, y 13, 1903.

explanation for the occurrence of glia elements in the growth.

Another attempt to explain the origin and nature of these tumors is made by Sternberg on the basis of developmental peculiarities. Sternberg believes that these tumors arise from embryonal rests of the so-called dorsal cranial nerves. Of these the trigeminus, acoustic, facial, glossopharyngeal and vagus arise from the so-called neural ridge, while the other cranial nerves are outgrowths of the original cerebral vesicles.

The neural ridge appears at an early embryonal date, when structural differentiation has not yet taken place. This affords an explanation of the presence of groups of atypical cells, which subsequently take on fibromatous, sarcomatous, or gliomatous proliferation.

*Symptomatology.*—This group of tumors courses under the clinical picture of tumors of the posterior fossa of the skull. The essential feature distinguishing these tumors from those originating within the substance of the brain-stem or cerebellum, is the early appearance of symptoms referable to a single

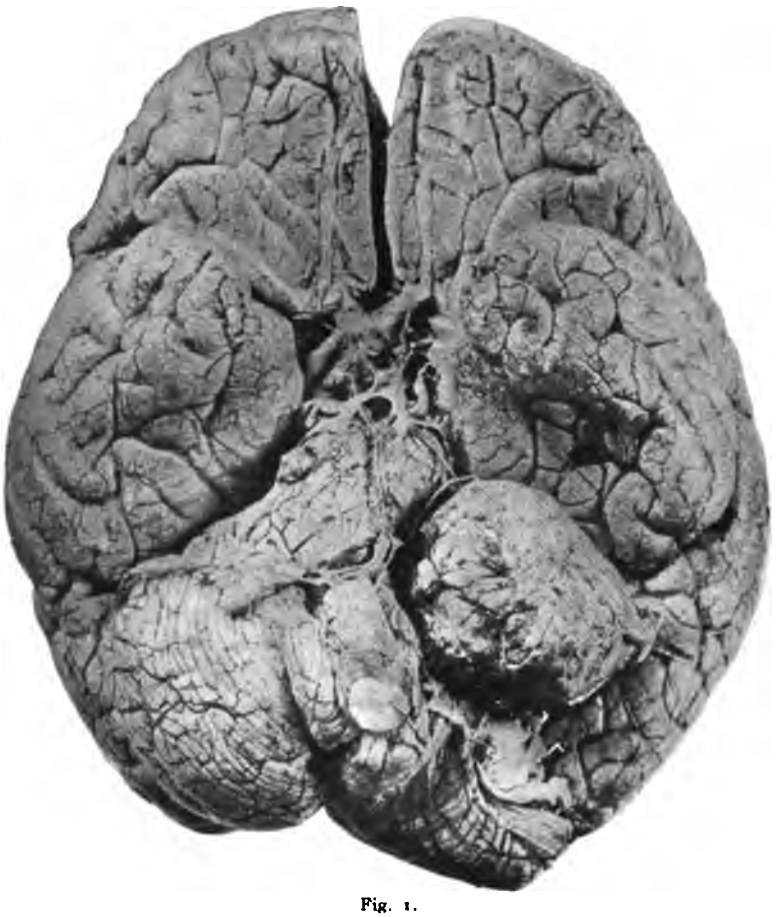

Fig. 1.

cranial nerve. These, because of the benign character and slow growth of the tumors may precede for a considerable time, any other focal or general symptom. As stated above, the nerves most frequently thus affected are the eighth and the fifth; hence tinnitus aurium with progressive diminution of hearing; attacks of Ménière's syndrome (aural vertigo) in the one case—obstinate and atypical attacks of facial neuralgia in the other case, will prove points of diagnostic importance.

With the further progress of the disease, structural changes of the fibers occur with objective clinical evidences. Because of histological peculiarities which these tumors possess in common with the neurofibromata of the spinal peripheral nerves, the conductivity of the fibers is not always completely abolished. Thus it happens that even in advanced stages, the affected nerves still preserve some of their functions.

With the increase in the size of the tumor, the neighboring parts, pons, cerebellum, medulla and basal nerves, show evidences of pressure: Peduncular ataxia, tendency to deviate or fall to the same or opposite side, cerebellar ataxia, nystagmus, irregularities in size and reaction of pupils, paralysis of associated movements of the eyeballs, dysarthria, dysphagia, homo- and contra-lateral and crossed paralyses of the extremities, paralysis of the facial or abducens of the peripheral type, motor disturbances of the palate or tongue, circulatory, respiratory, vasomotor phenomena and attacks of Adam-Stokes' syndrome.

*Diagnosis.*—The diagnosis of the condition rests upon the symptom complex of tumor of the posterior fossa of the skull, preceded by well-marked and long-continued symptoms, referable to disease of the fifth or eighth nerves. Naturally, many other pathological conditions in the posterior fossa may produce symptoms simulating quite closely those of the primary neurofibromata of the fifth or eighth nerve. (Aneurysm of vertebral artery, primary disease of the structures of base of skull or meninges.)

From the standpoint of differential diagnosis, the chronological relation of the neural symptoms to the general symptoms, the relative intensity of the neural and the other central symptoms, are determining factors.

*Prognosis.*—Owing to the proximity of vital centers these tumors share the fatal prognosis with other [illegible] lesions of this locality. The favorable features are the extreme chronicity of the condition, which, however, may at any time be interrupted by a sudden rapid proliferation of the growth, or by its to sarcomatous or other malignant change.

*Therapy.*—Removal of the growth by operative procedure offers the only hope. Because of the loose attachment of these tumors to their surroundings, we may hope, that in spite of the unfavorable location, a perfected surgical technique will improve the prognosis.

Case I.—Female, fifty-one years old. Disease began six years ago with headache, vomiting, vertigo, progressive left-sided hemiplegia. Static ataxia, falls toward left, paralysis of left seventh with changes of the electrical reactions, left-sided hemiparesis and hemiataxia, choked disk, left-sided deafness, nystagmus, left-sided abducens palsy, increased salivation, stupor, somnolence.

*Autopsy.*—Solitary neurofibroma in left ponto-medullo-cerebellar space. Left fifth adherent to surface of growth. Left eighth is not demonstrable.

C. M., a married Russian Jewess, entered the Montefiore Home July 6, 1894. The mental condition of the patient at the time of admission was such as to yield only meagre and unreliable data of her previous history. Dr. R. Abrahams of this city, who directed patient to the hospital and who had observed her for some time previously, kindly furnished the following notes: About one and one-half years ago, patient began to suffer from paralysis of the left side of the body, beginning in the leg, gradually ascending to the arm and finally invading the face of the same side. Speech was difficult; vision

and hearing of left side were impaired; memory was imperfect and vomiting was an occasional symptom.

During the patient's stay in the institution the following notes were taken: Family history: No definite information obtainable. Previous personal history: No definite information obtainable. Cause of present illness: Not definitely known; no history of traumatism or previous infectious disease. It is said to have begun about five years ago. The initial symptoms were occasional attacks of severe generalized headache, rarely accompanied by vomiting. The intervals between the attacks grew shorter, the attacks became more severe, and were more frequently associated with projectile vomiting. Since about one and one-half years left sided hemiplegia with slight speech disturbances. At time of admission, the patient complained of severe continuous headache, not particularly localized, vertigo, vomiting, impairment of sight and hearing, and annoying increase of salivation.

*Examination* showed: Static ataxia; swaying with closed and open eyes; inclines and falls toward left side; hemiplegico-atactic gait; pupils unequal, right smaller, all reactions present; when eyes turn toward left, the left eyeball stops at middle line;

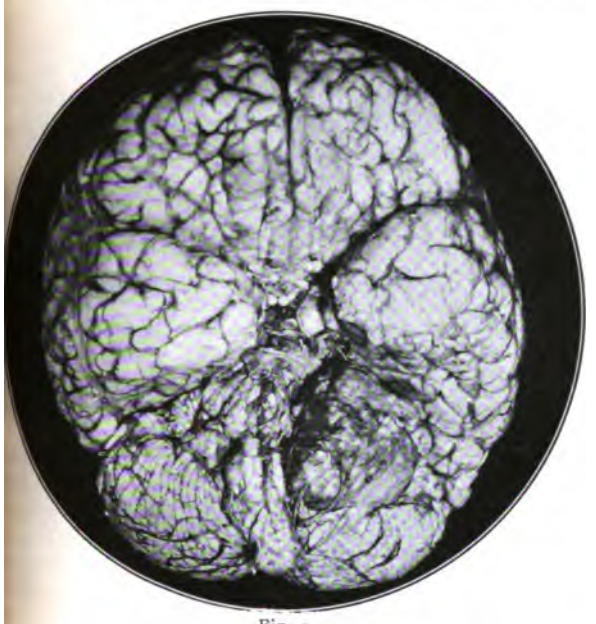

Fig. 2.

when turned toward right and upward, marked nystagmus (abducens palsy); paralysis of left facial with quantitative changes of electrical reactions; hearing impaired on both sides, particularly on left; moderate paralysis of left sided extremities with increased tendon reflexes; left sided hemiataxia; choked disk.

Up to time of death in May, 1895, these symptoms grew worse. Patient suffered particularly from headache and incessant drooling. Frequently serious attacks of somnolence were noted.

*Autopsy.*—Brain only was removed. A tumor the size of a bantam's egg was found in the left ponto-medullo-cerebellar space (Fig. 1). The growth was of firm, fibrous consistency, having a nodular surface. The attachments to the base consist of a few meningeal adhesions and blood-vessels. The left fifth is adherent to the surface of the growth. The tumor is readily removed, leaving a deep excavation on the pons, medulla, and cerebellum. The root of the eighth nerve could not be demonstrated, and was evidently torn away. Microscopically the growth presented the characteristics of a neurofibroma. The other cranial nerves were normal.

Case II (Dr. Onuf's case).—Male, forty-one years old. Onset: Headache, aural vertigo, tinnitus, later choked disk, facial neuralgia. Ataxia, deviation to right side, left-sided facial tic, left-sided deafness, choked disk, nystagmus, exaggeration of reflexes.

*Autopsy.*—Neurofibroma in the left ponto-medullo-cerebellar space, probably originating from the left acoustic. Curious cortical depressions.

S.I., Forty-six years old, janitor, born in the United States, was admitted to St. Catherine Hospital May 2, 1902. No specific history. Family history: No data of importance. Previous personal history: No venereal infection; no history of traumatism. Present disease: Began in the winter of 1902.

The first symptoms were headache in left occipital and left temporal regions, shooting pain with tinnitus and curious noises "like a steam pipe" in the left ear. The latter was particularly noticeable in recumbent position. In March, 1902, attacks of severe vertigo, with disturbances of equilibrium and vomiting, lasting from three to five minutes and recurring two to three times weekly. In April, sharp pain in both upper jaws, which persisted after removal of some defective teeth. At same time vision began to fail, and within two weeks only quantitative light perception was left. No diplopia.

*Status præsens:* Static and locomotor ataxia. Deviates to right side. Mentally excited and irritable. Dulness of olfactory sense on both sides. Choked disk, more marked on right side. Pupils widely dilated. No reactions. Rotatory nystagmus, also during ophthalmoscopic examination. No ocular palsies. Motor and sensory portion of fifth undisturbed. Occasional clonic twitchings in left facial musculature. No facial paralysis. Deafness on left side. No motor or sensory paralysis. No defects of coördination. Fine tremor of hands. Tendon reflexes not elicitable on upper extremities. Knee-jerks variable. In the early stages left knee-jerk weaker than right; later both knee-jerks exaggerated, especially right. Bilateral ankle clonus. Abdominal, epigastric, cremasteric reflexes absent. Plantar reflex exaggerated, flexion type.

Death occurred from typhoid fever.

*Autopsy.*—Brain only removed. In the left ponto-medullo-cerebellar space a firm tumor was found, enclosed in a smooth, glistening capsule, approximately the size of a hen's egg (Fig. 2). The surface is broken by irregular nodulations. On removal from its attachments a deep excavation is exposed, corresponding to the junction of pons, medulla, and cerebellum. This depression is 1½ inches long and 1½ inches wide. No nerve trunks can be demonstrated microscopically, passing into the capsule of the tumor. The left fifth nerve has been compressed by, but not incorporated in the tumor. The left sixth, seventh, and eighth nerves could not be demonstrated, having been torn off in removal. All other cranial nerves were normal. The tumor presented quite extensive areas of cystic degeneration with hemorrhages and necroses. Histologically the tumor is a neurofibroma; no evidences of sarcoma were noted.

By the Weigert method a nerve trunk is demonstrated entering the capsule of the tumor. At this point a network of nerve fibers courses around the periphery. A few scattered medullated nerve fibers are also situated centrally. The pyramids, lemniscus, fasciculus longitunalis posterior, posterior columns, showed no evidences of degeneration. The ascending root of the left fifth nerve showed slight evidences of atrophy.

The cerebral cortex was the seat of curious microscopical changes (Fig. 3). One similar spot was

observed in the upper part of the vermis-cerebelli. These consist of small depressions with a very sharply demarcated boundary. The larger number have the size of a pin's head; some are smaller,

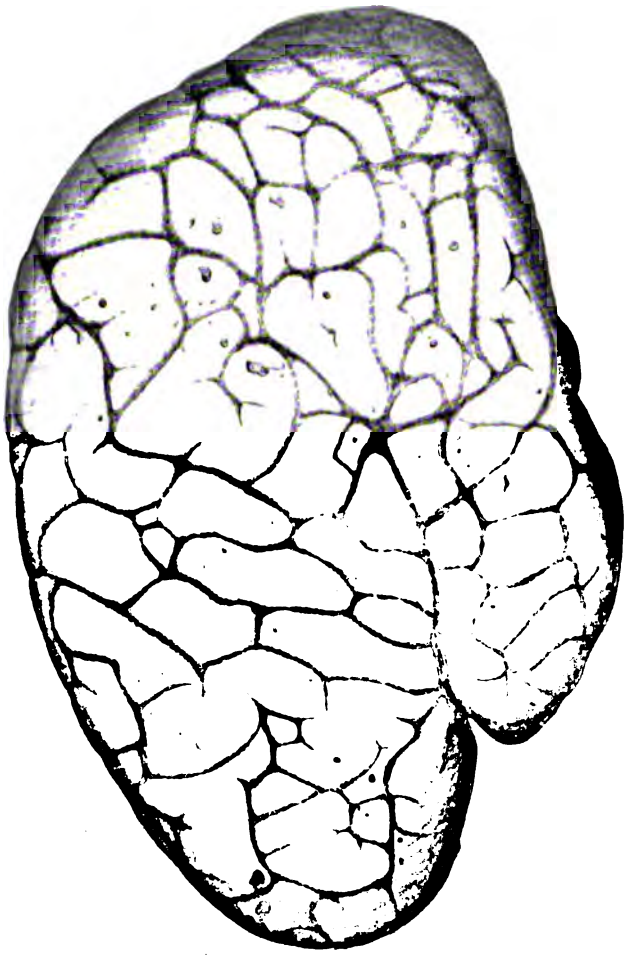

Fig. 3.

some larger. Many of them have projecting from the interior, a small fungoid tuft, which is adherent at the base, but unattached to the rim.

Many of the depressions contain no such tufts, they having apparently been torn away in the removal of the dura, as these projections were not only attached to the dura, but often perforated it. They were noted at the base of the brain, but more particularly over the temporal and parietal lobes.

No special abnormality was noted in the region of the Pachionian bodies; from which the tufts were easily distinguishable.

Histological examination by the Nissl and Van Gieson methods: In general these depressions correspond to the tip of a cortical medullary column, from which wave-like groups of spindle cells pass through the various layers of the cortex to the external surface. Here the cells protrude as structureless tufts seen macroscopically. The general cell type is fusiform with large oval nuclei and nucleoli of the ganglionic type. The cortical cells immediately enclosing and surrounding these plugs of spindle cells are normal in character and distribution. There are no evidences of inflammatory reaction.

Case III.—Russian, female, forty years old. Disease began about five years ago with attacks of headache. Static and locomotor ataxia, deviation to right side, paralysis of right seventh with changes of the electrical reactions, right-sided facial tic, hypæsthesia of right side of face tonus and reflexes variable, choked disk.

*Autopsy.*—Gliosarcoma in right ponto-medullo-cerebellar space, apparently originating from right fifth. Small tumor on left fifth nerve.

F. C., a Russian widow, forty years old, entered the Montefiore Home, October 11, 1898. Family history: No reliable data obtainable. Previous personal history: Negative. Onset and first symptoms of the disease were uncertain. Began about five years ago with attacks of severe headache apparently frontal. Some time afterward vomiting accompanied the headache. About one and a half years ago vision began to fail. Since December, 1897, inability to walk. The patient complains of loss of vision, attacks of headache and vomiting, almost constant and annoying pain in left half of body, particularly in left upper extremity.

The patient is of medium height, somewhat pale, poorly nourished. Skin flabby, markedly inelastic; a skin fold is slow in disappearing. The entire attitude of patient is strikingly immobile. Patient answers questions correctly in a very slow and monotonous fashion. All motor functions are executed in the same slow way. Patient is unable to stand or walk without assistance. Inclines and falls toward the right side (Fig. 4). Attitude hemiplegic. Gait hemiplegico-attactic.

*Head.*—Skull is not tender to percussion. Percussion note is dull on left side. Patient is unable to keep head balanced, it falls to right side like a dead weight. Face is covered with beads of perspiration on both sides; pallor and flush alternate; mechanical irritation of face evokes a long lasting vasomotor reaction. Lateral excursions of head are fairly normal; movements in antero-postero direction are limited and apparently painful. Mentally the patient is dull and apathetic, frequently going into a semi-stuporous state. Speech is slow and monotonous. No other decided mental defects.

Fig. 4.

*Cranial Nerves.*—Sense of smell is apparently dulled on both sides. The olfactory nasal reflex present, though very sluggish. The right optic nerve seen with difficulty. Contour cannot be traced. Corneal opacity. General optic reflex whitish. The left optic nerve much more easily seen. Contour indistinct. Central artery divides quickly above and below into small and very tortuous branches. Spots of hemorrhage are found here and there. Both retinæ very red; vision entirely gone.

Ocular axes are not parallel; no stable position of eyeballs; palpebral fissures are frequently varying in width, changing from position of semi-ptosis to one of normal width or even stare. The right palpebral fissure usually narrower than left. Pupils somewhat dilated, left somewhat wider. Direct pupillary reactions perverted; illumination dilates the pupils still further. Pain reaction present; other reactions cannot be tested. When patient is asked to move eyes in different directions, it is noticed that she moves eyeballs upward and downward normally, but less so to right and left—in fact, hardly any to left. Now and then the eyeballs twitch when turned in lateral direction. The conjunctival sacs are filled with purulent secretion, particularly on right side. The opticopalpebral reflexes are absent. The conjunctival reflexes are present, diminished, particularly on right side. Patient permits flies to promenade in right conjunctival sac.

Motor portion of fifth nerve is apparently normal. Sensibility on right half of face apparently dulled.

Total paralysis of right seventh nerve, including the upper branch. The face drawn to left side. Fibrillary and tonic contractions of musculature of right half of face frequently observed. Mechanical irritability of right-sided facial musculature is increased, but the response is very slow and vermicular. Faradic response of right facial musculature absent; with the galvanic current a partial degeneration reaction is obtained.

Sense of hearing is diminished on both sides, particularly on right.

Innervation of soft palate apparently normal and equal on both sides. No dysphagia. Pharyngeal reflexes absent. Tongue shows heavy coating, limited to right half; on protusion it deviates markedly to right side. The right half is flabbier, the electrical response of this half is markedly vermicular. Sense of taste is considerably impaired in anterior two-thirds of right half of tongue; in the posterior third and in the pharynx gustatory paræsthesias exist.

*Upper Extremities.*—The musculature is flabby, interdigital spaces sunken, particularly on right side. Marked hypotonia, particularly on right side. General motor weakness of both upper extremities. No incoördination. Tendon reflexes not elicitable. The muscles respond to stimuli, voluntary, mechanical and electrical, in a curious slow, almost vermicular, fashion. Sensibilities, as far as could be ascertained, unaltered.

*Lower Extremities.*—The position, attitude, and volume were without noteworthy features. General motor weakness. Marked hypotonia, particularly on right side. Patellar tendons soft. Knee and Achilles jerk cannot be elicited. Plantar reflex present; slow, flexion type. Slight ataxia; no evident disturbances of sensibility. Muscular responses the same as in the upper extremities.

*Trunk and Abdomen.*—No motor paralysis. Respiration superficial; intercostal functions fairly normal; diaphragmatic, weaker. Abdominal reflexes absent on left side. Neck is well formed. Thyroid gland not palpable. No demonstrable abnormalities of visceral organs. Sphincters occasionally derelict. Marked constipation. Urine negative. Pulse 96, temperature 97, respiration 6.

*Course.* — October 16, 2.40 P.M.: Patient is perspiring profusely, drools, passes urine involuntary.

October 18: Complains of severe pain throughout left half of body, particularly left half of face and left upper extremity; the latter is uncomfortable in any position.

October 20: Attack of profuse perspiration, increased salivation.

October 25: Ocular excursions normal. Knee-jerks present on both sides, exhaustible and intermittent on right, always demonstrable on left. Achilles reflex ditto.

October 30: Lateral ocular excursions limited; normal in other directions. Achilles and knee-jerks obtainable.

November 6: Ocular excursions to right side limited and accompanied by nystagmus. Knee- and Achilles jerks not obtainable.

November 12: Complains of pain in left eye and left upper extremity, severe occipital headache. Knee and Achilles jerks not obtainable. Ocular excursions normal. Considerable ataxia in both upper and lower extremities of left side. Marked diminution of motor power of left lower extremity. Now and then a knee-jerk is obtained, vermicular without locomotor effect. On right, Achilles jerk is present, intermittent; also on left.

November 21: Patient is semi-conscious; does not recognize any one; profuse perspiration. Temperature 97°, pulse 100, respiration 8. Patient is restless, throws arms and legs about; this condition lasted half an hour.

November 28: Patient complains of pain in left upper extremity. Knee-jerks elicitable, varying in intensity; so also muscular tone. Achilles jerk not elicitable.

From now until the middle of January the state of the tendon reflexes and muscle tonus of the lower extremities were examined daily. This examination revealed the following facts: (1) The inconstancy of these phenomena, varying daily even in a short time during the same examination. (2) The constant diminution of the right-sided tendon jerks and muscle tonus. (3) The occasional exaggeration of both tendon jerks and muscle tonus on left side; on this side a spurious ankle clonus was frequently observed.

January 14: Patient complains of general weakness and pain in eyes, particularly in right. Neuroparalytic keratitis of right side. Right palpebral fissure smaller. Right-sided extremities show hypotonia; left sided, hypertonia. Left knee-jerk strong; right, diminished and exhaustible. Right-sided Achilles jerk present; on left side, ankle clonus.

February 15: Right eye considerably congested, cornea hazy, showing a number of abrasions; conjunctival reflexes present, diminished on right side. Deep sensibility of upper lids preserved. Ocular excursions show irregular deficiencies, are jerky. The excursions of each eye, separately and in conjunction, show weakness of the superior oblique; all ocular movements are slow, hesitating, interrupted, and jerky. Pain sense considerably diminished on right half of face. Left knee-jerk present; slight left-sided ankle clonus; right-sided tendon reflexes weaker.

March 7: Tendon reflexes of lower extremities not elicitable. A few minutes later left knee-jerk present and left-sided ankle clonus. Reflexes on right side absent.

March 9: Patient is comatose; does not answer questions. Rectal and vesical incontinence. Both patellar reflexes lively. Both Achilles jerks absent; both plantar reflexes absent.

May 25 : Both lower extremities drawn up. Acute decubitus.

June 8 : Patient is again in stuporous condition. Respiration 8, irregular; pulse 120°, temperature

Fig. 5.

100°. Both knee-jerks are present. Ankle clonus on both sides.

Patient died in this condition June 9, at 4 A.M.

*Autopsy.*—Post-mortem examination revealed the presence of a tumor in the right ponto-medullo-cerebellar space. (Fig. 5). The tumor was about the size of a walnut, nodular, of firm consistency; the

Fig. 6.

pons is pushed to left, the medulla is slightly pressed upon.

There were absolutely no traces of the right fifth nerve demonstrable. The tumor was loosely attached to the surroundings. On the left side the root of the fifth nerve is converted into a spongy mass four to five times the size of a normal root. This tumefaction is made up of loose areolar tissue, containing large blood-vessels and ganglion cells.

It is difficult to identify the eighth nerve of the right side. Microscopically the tumor showed the structure of a gliosarcoma. Fillet and pyramidal tracts unchanged. In the upper cervical region there are evidences of old ascending degenerations, of the columns of Goll and Burdach, and of the anterolateral tract. Marked degeneration of ascending root of right fifth. Nerve roots and nuclei of medulla normal.

CASE IV.—Early deafness, since fifteen years of age. Onset: Headaches and aural vertigo; later, dimness of sight. Deviates to right side; static and locomotor ataxia, inequality of pupils; paresis of right abducens; paralysis of right seventh with changes of electrical reaction; choked disk; deafness on both sides; hemiplegia cruciata, exaggerated reflexes of left lower and right upper extremity, left-sided Babinsky.

*Autopsy.*—Multiple endotheliomata of dura mater (10 ocounted), bilateral neurofibroma of acoustic nerves.

S. B., forty-two years old, a Russian woman, was admitted to the Montefiore Home on May 5, 1900. Family history (obtained from daughter): Patient's mother died suddenly from unknown cause; her father, four sisters, and two brothers are all living and well. Previous personal history: Had typhoid fever at age of seven; became suddenly deaf at fifteen; gave birth to twelve living children and had two miscarriages. Five children died in infancy from infectious diseases; the others are well. Present disease is said to have begun two years ago. The first symptoms were headache and attacks of severe vertigo, which made the patient fall to floor without loss of consciousness. Five minutes after an attack patient got up and continued about her housework.

She gradually became weaker and more helpless, and at the end of one year was unable to move without assistance. Vision began to fail about eight months ago. Patient vomited only once during the entire course of the disease.

The patient is below medium height, rather poorly nourished, muscles very flabby, particularly the right-sided ones. Marked static and locomotor ataxia. Patient has a tendency to fall toward the right side. Patient is totally deaf and almost totally blind, and therefore the examination is in many respects insufficient.

*Head and Cranial Nerves.*—Excursions of head limited in all directions. No tenderness of skull. Sense of smell considerably diminished on left side. Bilateral choked disk going into atrophy. Convergent strabismus. Marked weakness of right external rectus. Pupils unequal; right larger. All reactions present. Paralysis of all branches of right facial nerve with partial degeneration reaction. Tongue deviates to right and shows slight fibrillary tremor.

*Upper Extremities.*—Considerable diminution of motor power of right upper extremity; slight ataxia of left upper extremity; moderate contractures in both, particularly of the right.

Patient usually favors the right upper extremity. Reflexes in both upper extremities lively, particularly right sided. No sensory disturbances. No atrophies.

*Lower Extremities.*—Considerable motor paralysis of left lower extremity. Considerable contracture of right lower extremity. Patellar reflex is lively on both sides, particularly on left. Achilles reflex lively on left, diminished on right. Plantar reflex present, flexor response, bilateral pes cavus. No incoördination. Loss of deep sensibility in both lower extremities.

May 21, 1901: Patient drinks large quantities of water. Complains of thirst and of frequent micturition. The examination of the visceral organs is negative.

The picture remained unchanged until patient died of respiratory paralysis August 4, 1901.

*Autopsy.*—Only the brain was removed. The dura mater was found to be the seat of multiple tumors of various sizes, from a split pea to a cherry (Fig. 6). The larger ones produced depressions on the cortex. One hundred individual tumors were counted, but there were many more.

The larger ones were found: (1) On the mesial surface of the left frontal lobe. (2) Just anteriorly to the right para-central lobe and in the middle of the right Rolandic area. (3) Over the left calcarine fissure. (4) The entire falx was a tumor mass the size of a hen's egg, pressing on the mesial surface of the hemispheres. Only here were there evidences of retrograde metamorphosis.

The fifth, sixth, seventh, and eighth nerves of the right side were pressed upon.

A tumor was found in each ponto-medullo-cerebellar space. (Fig. 7). These tumors were of firm consistency; the surface nodular. They were approximately the size of a plum; the right was larger than the left.

The third, fourth, and fifth nerves of the right side were not found.

The right sixth nerve showed a nodular swelling the size of a split pea, and the left sixth nerve was the seat of minute swellings and tortuosities. Similar varicosities were also noted on the seventh, eighth, ninth, and tenth nerves of both sides.

Histologically the tumors of the ponto-medullo-cerebellar spaces and the varicosities and tumefactions of the basal nerves, showed the typical characteristics of neurofibromata.

The dural tumors were psammomata of the fibrous and alveolar variety; the first showing typically fibromatous structure, and the others groups of round cells, separated by an alveolar network. Nowhere evidences of sarcomatous degeneration. The pyramidal and sensory tracts of pons and medulla were unaltered. The processus cerebelli ad pontum showed atrophy and sclerosis.

Case V. (Preliminary report.)—Male, forty-two years old. Disease began six years ago. Tinnitus in left ear and occasional headaches. Later impairment of vision and uncertainty of gait. Static and locomotor ataxia; deviates to left side; left hemiasynergia and hemiataxia; exaggerated reflexes; deafness of left ear; paresis of left seventh; paræsthesias in left fifth; choked disk; operation by Dr. Geo. Woolsey. Removal of tumor from left ponto-medullo-cerebellar space. Death.

Patient was a Jewish pedlar, aged forty-two years. No syphilitic history. Eight years before head trauma (struck with fist). Six years before annoying tinnitus in the left ear; later diminution of hearing. Past four years subject to occasional occipital headaches and vertigo. During past year headaches and vertigo much worse, with cloudiness of vision. For the last six months there has been unsteadiness of gait.

*Status Præsens:* Watch tick not perceptible in left ear. Tuning fork vibrations very faint to aërial and bone conduction on the left. Paresis of left seventh nerve, more apparent in upper branch—with slight quantitative electrical changes. Paræsthesia in sensory distribution of left fifth with objective sensory disturbances. Moderate dysarthria. Pupils unequal, left wider than right. Reactions present. Amblyopia. Choked disk. A slow nystagmus in extreme positions. Hemiasynergia and hemiataxia of left side. Station: falls to left. Progression: deviates to left. Tendon reflexes active. Knee-jerk exaggerated; the left more than the right. No ankle clonus. Skin reflexes present. No Babinsky.

Operation May 7, 1903, by Dr. George Woolsey.

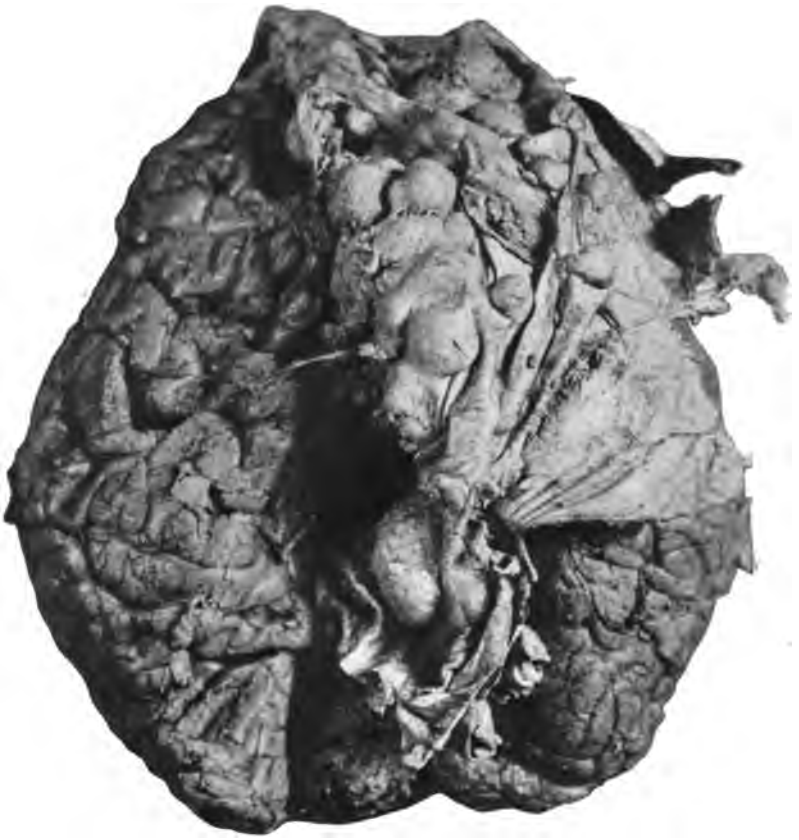

Fig. 7.

The occipital bone was trephined on the left side on its postero-inferior surface. The finger passed along the under surface of the cerebellum located a nodular growth in the left ponto-medullo-cerebellar angle about the size of a hen's egg. The tumor was broken up by gentle manipulations with the index-finger and removed in fragments.

Patient died twelve hours later, never having reacted, with symptoms pointing to implication of the cardiac and respiratory centers.

Histologically, the tumor was a neurofibroma.

*Conclusions.*—The foregoing cases show a common origin from cranial nerve trunks. Their pathological structure is of a kindred nature—neurofibromatosis, pure or in various stages of metamorphosis and transformation. The locality is almost identical—the angle formed by the junction of pons, medulla, and cerebellum. Their symptomatology, because of this localization, is, in the essential features, analogous,

The certainty of localization, the essentially benign nature of the growths, their loose attachment to the meninges and nerve trunks, distinguish this group of intracranial tumors as a most favorable one for surgical interference.

In view of all this, we find justification for the suggestion to assign a separate place to this syndrome in the group of intracranial tumors.

## THE PRESENT STATUS OF THE TREATMENT OF LATERAL CURVATURE.

BY JACOB TESCHNER, M.D.,
NEW YORK.

MULTIFARIOUS papers exploiting ideas and opinions upon the question of treatment of lateral curvature appear from time to time, showing the unsettled state of affairs regarding the proper treatment and result in this condition. The late Dr. A. M. Phelps says:[1] "Lateral curvature of the spine arises before us each year like a specter. From every clinic in the country the orthopedic surgeon is deluging societies and medical journals with literature upon the subject. It is interesting to note that from the earliest records we can find upon the subject down to the present time the positive position of the author is only to be retreated from a year or two later."

It is high time in the writer's opinion concisely to lay before the general practitioner especially the true status of the treatments to which their patients are subjected and what they can expect in results.

Ten years ago our faith rested upon mechanical supports which we gave our patients in the shape of braces of all varieties of construction, plaster, and leather corsets, etc., and supplemented their uses by suspension and Swedish movements or some other show of exercise. The mechanical apparatus was to act as a retaining appliance, and the little exercise, which was supposed to act in a corrective direction was absolutely nullified by the retaining or supporting device. Some few began to hope for benefit in forcible redressment, and added that form of treatment to the one before described.

In 1895, after exhaustive experimentation and study, the writer published his paper on "The Treatment of Postural Deformities of the Trunk by Means of Rapid and Thorough Physical Development,"[2] in which he demonstrated beyond a doubt the superiority of the method of treatment devised by him, in that the results were not conjectural, but visible and rapid.

In that paper the author was the first to state, against the concensus of opinion of orthopedic surgeons, that rotation, even when bony and ligamentous changes had occurred, could be overcome. He strictly forbade the use of any retaining, immobilizing or supporting, apparatus of any kinds, because "each and every one will, to a greater or lesser extent, interfere with the mobility of the spine, and in that manner deprive the back, chest, and abdominal muscles of that perfect freedom of action which is a necessary and powerful adjunct in the treatment by gymnastics."

Since 1894 the results, even in the severe forms of curvature, have been uniformly good in hundreds of the author's cases.

How was this method received by orthopedists? What have they done since? What opinions do they hold, and what are they doing now? And what are their objections to carrying out this method in their practices? Writings and publicly expressed opinions supply some of the answers.

The method was looked upon as novel and amusing by some, too troublesome and taxing in its application by others, and still others saw its value but remained discreetly silent. Since then much has been written showing the trend of opinion that braces should be avoided whenever possible, surgeons gradually depending more and more upon exercises indifferently taught by incompetent persons.

In 1900 an indefatigable worker, Dr. Robert W. Lovett of Boston, with the collaboration of Prof. Thos. Dwight of Harvard Medical School, and Professor Hollis of Harvard University, gave the subject of "The Mechanics of Lateral Curvature of the Spine"[3] his closest attention, studying the mechanics upon the cadaver and artists' models. Drawing his conclusions, under the caption of "Treatment," he says: "Of course, theoretical conditions such as those given above are of value only in so far as they may influence prophylaxis and treatment." Under this caption, while he states that "the writer has endeavored to deal only with the broader aspect of the question and to avoid generalizations from clinical experience," his only reference to clinical experience is the following, viz., "It is easy to see from this point of view why symmetrical gymnastics such as those described by Teschner,[4] are of so much value; and it also explains, what many of us have found out empirically, that it is desirable to hold and exercise the spine in positions of extension." He further says: "By calling upon the intrinsic property of the spine to reverse in extended positions the rotation acquired in flexed positions, it would seem that we were pursuing a most rational course." Under the caption of "Gymnastics," he says: "Safety lies in prescribing only exercises of which one can estimate the anatomical effect."

That his conclusions are correct there can be no doubt; then why not carry out the deductions and apply them in practice in the treatment of patients?

In 1901, in an article[5] upon the treatment of fixed scolioses, he advocates forcible correction as preliminary only to gymnastic treatment, and he "would not wish to be understood to advocate the use of corrective plaster jackets except as a temporary means to secure a better foundation for better gymnastic or, if necessary, mechanical treatment." In arguing in favor of forcible correction and retention in plaster he says that "forcible correction is admittedly in its experimental stage."

Dr. E. H. Bradford[6] of Boston, in speaking of fixed cases, says: "This difficulty makes corrective treatment of advanced cases of scoliosis impossible, as osteotomy is not feasible in lateral curvature, and the amount of pressure necessary for altering the shape of grown bones in the trunk is so great that correction becomes impossible. . . . The surgical indications for treatment of lateral curvatures are now well understood. It is generally agreed that when the muscles are weak, and a faulty atti-

tude favored by weak muscles, the muscles should be developed."

Upon this follows the statement that "during the growing period faulty attitudes should be prevented by retaining apparatus if necessary. . . . In other words, the practitioner needs to consider: (1) Measures to promote flexibility in a localized position of the spine. Means for the greatest possible rectification of errors. (2) Gymnastic exercises of such muscles as may be needed in given cases to maintain corrected attitudes. (3) Appliances preventing faulty positions of the spine. (4) Means of recording condition and progress of the case.

"In practice the cases may, for convenience, be classified as follows: Cases needing correction, demanding considerable pressure and the use of a removable jacket, with or without exercises. Cases requiring flexibility and passive exercises, conducted by the surgeon or nurse. Cases suited for flexibility exercises done by the patient. Cases needing developing exercises measured by graded work and strength tests. Cases needing measures for improvement in carriage recorded by measure and photograph, to be kept under observation. . . . In the treatment of cases coming under his care, the surgeon will find the greatest difficulty in his attempts to increase the flexibility of the spine, as the development of muscles is pretty well understood.

Then follow the descriptions of devices for acquiring flexibility. "For means of muscular development, dumb bells can be made to answer every requirement under proper guidance. The use of heavy exercises with the addition of heavy bars is of the greatest assistance, as has been shown by Teschner and Erich."

In the second edition of Bradford and Lovett's "Orthopedic Surgery"[1] mention is made of heavy gymnastics, and they say: "This has been thoroughly carried out by Teschner of New York."

Fig. 1. Back of patient, showing severe rotary-lateral curve with a very deep depression under the right scapula, and marked elevation of the left hip October 4. 1898.

Fig. 2. Back of patient showing improvement in the curve—obliteration of the depression under the right scapula, the widening of the entire back, and the equalization of the hips. May 27, 1899.

After reading Dr. Lovett's second paper and the above-mentioned one of Dr. Bradford, where should one look for the cause of such an indefinite attitude?

Neither of the gentlemen has ever seen a demonstration by the author of this method, and as no one can be expected to obtain results by it unless he has not only seen it but has also been properly trained in its application, the cause is obvious.

Had he had the necessary training Dr. Lovett would never have advocated forcible correction and retention in plaster jackets as a foundation for gymnastic treatment, knowing that such a preparation must necessarily weaken the muscularity of the patient and give a very poor foundation. When one sees what has been accomplished in reducing a deformity in a case of severest type in a very short time (Figs. 1 and 2) by the author's method, why should a case be subjected to forcible correction which is "admittedly in its experimental stage"?

As an illustration of what has been accomplished in a case of the severest type of fixed rotary-lateral curvature, an example of the class of cases in which Dr. Bradford says that correction becomes impossible, reproductions of photographs of a patient of this class, whose spine was thoroughly rigid and who, by reason of his deformity, suffered from dyspnœa, cyanosis, and impaired cardiac action, are shown before and after the author's treatment by heavy gymnastics.

After this patient had been under treatment for a short time, his cyanosis and dyspnœa disappeared and he was equal to extraordinary physical exertion without the slightest sign of distress or fatigue.

The statements made by Dr. Bradford are hardly compatible with his eminence as an orthopedist. After stating that corrective treatment of scoliosis is impossible, he then says that the indications for treatment "are now well understood and that the muscles should be developed." That "during the growing period faulty attitudes should be prevented by retaining apparatus, if necessary." Faulty attitudes should be corrected during any period, and a retaining brace will only weaken the already weak muscles, without attaining the proper attitude.

How can any one "promote flexibility" in any "localized position of the spine." without promoting it in the entire spine? Why should "such muscles as may be needed in given cases to maintain corrected attitudes" be selected for gymnastic exercises, when all the muscles of the trunk and lower extremities coördinately control attitude? What appliance have we that has the virtue of "preventing faulty positions of the spine"? If there be such an apparatus the whole question of treatment is solved.

In his classification, for convenience in practice, he mentions "cases needing correction demanding considerable pressure," when he previously stated that correction by pressure was practically impossible. He mentions cases requiring flexibility exercises done by surgeon, nurse or patient.

All cases require increased flexibility, and why if, as he states that "the surgeon will find the greatest difficulty in his attempt to increase the flexibility of the spine, as the development of the muscles is pretty well understood," should it be left to the patient or nurse? Is either of them more competent than the surgeon? Is the fact that "the development of muscles is pretty well understood." a barrier to the acquirement of flexibility?

He also mentions cases "needing developing exercises" and "cases needing measures for improvement in carriage recorded by measures and photographs," etc. Does he mean to imply that the

following photographic reproductions of his schematic outline drawings (a part of his paper) are true or proper records of cases?

All the cases he refers to need development exercises, and they all need "measures for improvement in carriage," which are simply development and education of muscles whether they be recorded or not.

Fig. 3. Side view, showing the marked antero-posterior deformity, October 4, 1898.

Fig. 4. Side view showing reduction of the antero-posterior curve, and the development of the chest. May 27, 1899.

He does say, however, "The use of heavy exercises with the addition of heavy bars is of the greatest assistance, as has been shown by Teschner and Erich" For this we must give him due credit.

Whitman, in his work on Orthopedic Surgery,[8] says: "One of the most effective systems of treatment of lateral curvature is that advocated by Teschner of New York." Dr. Whitman has seen demonstrations of the system and has taken advantage of opportunities to see patients treated and has been shown results. Hence his statement.

How many cases to which he has given his personal attention, as the author does in his cases has he treated by this system? It is reasonably certain that the answer will be, not one. And why? Not that the results could not be obtained, but because of the frequently expressed opinions which make this method impracticable. (1) It is laborious and taxing—mentally and physically—in its application. (2) The inability to demand and receive a sufficient fee for the time expended with a patient. (3) The time to be devoted to a proper training. (4) And the greatest drawback to its adoption being the supposed moral effect that it would produce upon the laity, of a physician of high standing falling to the level of an instructor in gymnastics.

Are these objections tenable? The answer is, decidedly not.

As for the moral effect upon the laity, the dignity of a physicians in no way impaired by any plan of treatment which he may personally apply, providing that he himself have a sufficient amount of skill properly to apply that plan of treatment in an intelligent and thorough manner.

There are several orthopedists in this city and elsewhere who, pinning their faith to the method described by me, attempt it without the slightest knowledge of its proper application, and generally through the medium of a masseuse or Swedish gymnast who knows still less than the physician who orders it.

It is a very common occurrence to have a woman call upon me with a card or letter of introduction from a prominent orthopedist, announcing that she is a gymnast in charge of Dr. Blank's curvature cases, and that he would be indebted, if this person could be shown how to treat these cases by the system of heavy gymnastics. In the paper before alluded to I distinctly say: "This system of work should only be applied by the physician, and he must himself have been trained to the work, to intelligently guide those whom he seeks to benefit. The work must be careful, systematic, and regular. Perfunctory work will not do."

The author has not retreated from the opinions he held in 1895 as to the value of his method in the treatment of curvatures and kindred deformities,

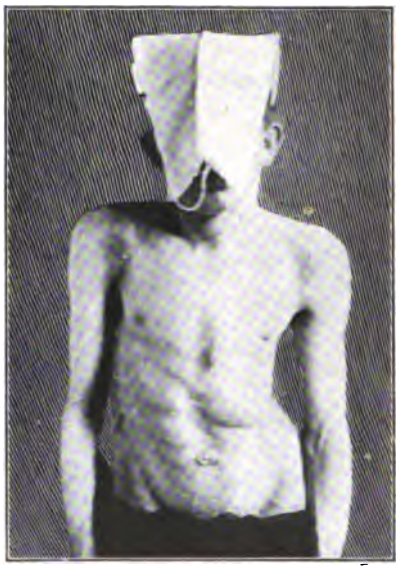

Fig. 5. Front view, showing flat chest, prominent left hip and twisting of the abdomen, with the prominence of the lower ribs on the left side. October 4, 1898

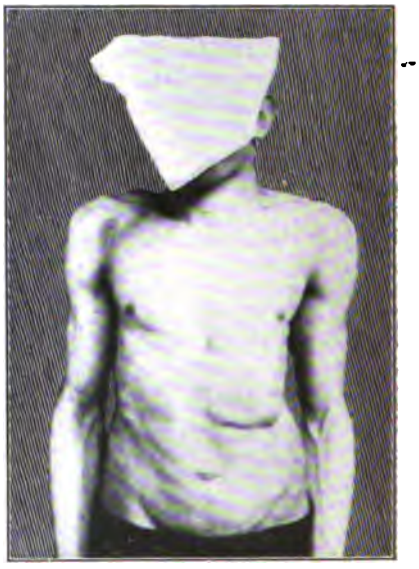

Fig. 6. Front view, showing chest development, reduction of the costal prominence, of the left hip and the straightening of the trunk. May 27, 1899.

but has become more and more enthusiastic as to its value by reason of his results and their rapidity, and is firmly convinced that it will in time be the only mainstay of physicians who treat scoliosis.

Under these conditions, does the general practitioner do his full duty toward his patient by shifting

the responsibility of the case from his shoulders to those of the orthopedist to whom he refers it, when he (the orthopedist) and most of his colleagues admit that they are at sea as to proper corrective treatment?

Or does the physician who believes in exercise do his duty when he advises that a patient be sent to a gymnasium where the work is almost always in-

Fig. 7. The same patient, showing muscular development, and one of the exercises which assists in straightening out the curve.

different or worse? Or, when he sends him to an institution where complicated and highly polished machinery imposes itself upon him and blinds his mental vision to the futility of its purpose?

These questions can be answered by the practitioners themselves if they will examine the cases which they so referred several years ago and see

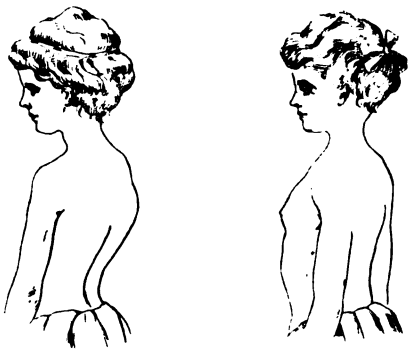

Fig. 8.

what has been left undone. The method comprises a rational rapid development and education of the muscles, and an ability of the patient to correct his or her own deformity by his or her own muscular efforts, and is purely physiological.

In closing, it might be well to direct the attention of the general practitioner to the necessity of carefully and understandingly examining the children whose posture and gait are faulty, to advise the proper treatment for them, to explain the difference between ordinary gymnastics and the proper treatment and to do it early when a few months' care

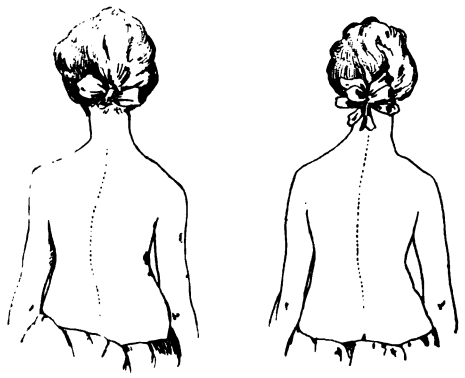

Fig. 9.

would suffice to bring about an improved carriage and a stimulation to proper growth and development

# INTESTINAL FERMENTATION, AS IT INTERESTS THE SURGEON.*

By ROBERT T. MORRIS, M.D.,
NEW YORK.

Cases in which there is an evident surgical factor in the production of an undue amount of intestinal fermentation are not the ones under consideration in this paper. Cases of intestinal fermentation that are commonly treated by medical means, and in which the surgical cause is usually overlooked are so frequently met with in practice that it may be well to classify some of them. They are cases in which the trouble is lightly set down as due to "faulty digestion" or "constipation," but we must go back of that in order to start right in comprehending the situation.

At the outset we may define the cases under consideration in a general way as ones in which there is an apparent functional neurosis of the digestive apparatus, with irritation of the intimate sympathetic ganglia of the bowel wall (Meissner's and Auerbach's plexuses) secondary to irritation of the larger sympathetic ganglia of the abdomen, and these primarily irritated through reflex from a peripheral cause. As a result of the functional neurosis the digestive process is incomplete, and saprophytes destroy the legitimate pabulum for the secretions of the alimentary tract. The round of autointoxication and of metabolic fault then follows. Our study therefore consists in noting not the symptoms alone, but in arranging them in such order that they point toward the primary and fundamental cause for the disturbance; and the peripheral irritations act so

*A paper read at the meeting of the Society of Alumni of Bellevue Hospital, November 4, 1903.

insidiously that the very nicest diagnostic acumen is called into play. These patients tell us of trips to the famous baths of Europe, of stomach lavage, of Christian Science, of treatment at the hands of vibrationists—to say nothing of the inevitable favorite prescription, and all without permanent benefit, excepting while treatment is persistently maintained.

In enumerating a list of the peripheral irritators it will be noted, I think, that the ones which most closely affect the great sympathetic ganglia are those resulting in the greatest degree of intestinal fermentation. Let us take for the first group of peripheral irritators the peritoneal adhesions, and it will be noted that adhesions in the pelvis do not cause so much reflex as adhesions about the appendix and cæcum. These, in turn, are less disturbing than adhesions about the gall-bladder, and returning to a distance from the great ganglia we find comparatively little reflex from adhesions about the sigmoid flexure of the colon. Peritoneal adhesions occur most frequently, I believe, in the regions enumerated, and in the order in which the sites are noted.

In making a search of the abdomen for adhesion causes for intestinal fermentation we are apt to discover any adhesions in the pelvis or about the appendix readily enough. Adhesions about the region of the sigmoid are not often discovered, excepting at post-mortem examination. Adhesions which are most often overlooked, and yet which are among the very common ones, are those about the gall-bladder, resulting from infective cholecystitis. This particular subject is a very new one and one that has recently been elaborated in a path-making paper by Dr. Musser of Philadelphia. This paper will probably in the end be held to rank with the paper of Fitz, in 1886, on the subject of appendicitis. Infective cholecystitis, with or without the presence of gallstones, is apparently one of the commonest of abdominal disorders. The cases are apt to be ascribed to "acute indigestion," and to as many things as we used to find in place of appendicitis.

I have at present under treatment two cases that had been treated at length as cases of dilatation of the stomach by careful diagnosticians who had no explanation for the dilatation, and yet, on operation for the purpose of taking up the stomach wall by suture, it was found that the trouble was wholly due to the presence of gall-bladder adhesions which inhibited peristalsis at the pylorus. The adhesions were from overlooked attacks of subacute infective cholecystitis.

One of the commonest groups of cases of intestinal fermentation in which the cause is overlooked depends upon the presence of the appendix vermiformis in the process of undergoing normal involution. It is only very recently that our attention has been attracted to this factor, but a knowledge of its influence increases the satisfaction of modern practice of medicine. The appendix is apt to undergo normal involution changes which result in the replacement of the lymphoid and mucous layers with connective tissue. The connective tissue contracts and irritates terminal filaments of entrapped sensory and sympathetic nerves, which apparently disappear more slowly than other structures of the appendix. The reflex irritation from this peripheral cause sets up a train of symptoms generally classified as "intestinal fermentation." On account of my interest in this particular form of appendix trouble the appendices are in some quarters given my name, but they should preferably be called "scar appendices" or "involution appendices," for the reason that they were described by Senn and Ribbert before I took up the study of the symptoms that they produced.

It is not very difficult to make a diagnosis in these cases by the association of symptoms of persistent discomfort in the appendix region, a hard appendix on palpation, and intestinal fermentation which responds to treatment, only to return promptly when treatment is neglected.

Many cases of intestinal fermentation center about the presence of a loose kidney, or of general enteroptosis, but such cases are worked out pretty regularly nowadays by the good diagnostician, and the ones that are suitable for surgical treatment soon lose their intestinal fermentation, mucous colitis, or whatever functional neurosis was dependent upon the peripheral irritation.

A very large group of cases of intestinal fermentation is dependent upon eyestrain. These cases are perhaps quite as often overlooked as any others, but as soon as we have all become familiar with the external signs of eyestrain, fewer of the cases will get to the surgeon with the diagnosis of some abdominal disorder. The ones that I see are sent to the office most often with the request to have the appendix examined, because the distension of the cæcum is apt to cause more pain than distension of other parts of the bowel, and attention is attracted to this region. If there are external evidences of eyestrain these cases are referred to the ophthalmologist, along with my cases of "nervous dyspepsia" and "gastric neuralgia," and some of the most brilliant results that I have observed in any kind of medical practice have come out of the treatment that was instituted.

The different kinds of cases of intestinal fermentation so far under consideration appear chiefly after adult life has been reached, but one very large group marked by "chronic constipation since childhood," depends wholly upon the presence of hypertrophic rectal valves. It is a new revelation to most of us who have not previously been familiar with this subject when we look into the rectum with a properly constructed speculum, and see a large swollen rectal valve occluding the passage of fæces, and know that the patient has carried this congenital defect all of his life, but out of sight of those of us who are so busy that we are in a hurry to get to the next case.

I am curious to know what proportion of cases of intestinal fermentation are really medical cases, and not curable by surgical resources. Even so-called lithæmic cases of intestinal fermentation may clear up, lithæmia and all, so soon as the primary cause is out of the way. Patients whose intestinal fermentation is said to be due to "improper food" often find that they can eat freely and indiscriminately of almost anything in the way of food once their intimate ganglia of the bowel wall are free from irritation.

58 West Fifty-sixth Street.

**Some Effects of Tobacco.**—J. A. Henton White reports several cases in which the poison from smoking produced symptoms which were concentrated on either the respiratory, the cardiac, or the alimentary system. These exaggerated symptoms all occur in a modified form in seasoned and seasoning smokers who exceed their dose. They also all point to there being such a condition as hereditary incapacity to smoke. In subjects whose alimentary canal is upset, the pain is described as being of a peculiar grinding character. Neuralgia of the thoracic and humeral varieties is another symptom, produced especially by Havana cigars, whether these symptoms are due to a neuritis or a more central affection is disputed—possibly both may occur together or separately.—*The Birmingham Medical Review*, September, 1903.

# THE SUBMUCOUS RESECTION OF THE NASAL SEPTUM.*

By FELIX COHN, M.D.,
NEW YORK.

It is an achievement of the last ten years in rhinology to have called attention to the importance of anomalies of the septum in their relation to the condition of the mucous membrane of the nasal passages. Nor is it only the marked deformities which tend to maintain the continued catarrhal changes with all their annoying consequences to the individual; on the contrary, frequently circumscript deflections, an anterior deviation, a dislocation of the columnar cartilage, a moderate curvature of a portion of the septum, high up—for instance, opposite the middle turbinated and interfering with normal aëration and drainage, or causing states of rarefaction which in their turn produce hyperæmic conditions of the mucous membrane—are sufficient causes for pathological changes which seemingly appear to resist all ordinary treatment. The relief to the patient upon the attempt at treatment of such changes in the nasal passages is only short-lived and temporary. The hypertrophied turbinated, in spite of having been cauterized or snared, becomes again turgescent; the frequent colds, extending to the nasopharynx and tonsillar region, return. As soon as the attention in these cases is directed to the cause, and even an apparently slight septal deformity is corrected, the subjective discomfort of the patient vanishes like a flash, the pharyngitis, the hawking, the endless recurring attacks of coryza and tonsillitis cease, and the patient is permanently cured.

To American rhinology belongs the credit of having achieved the most brilliant results in this direction, in the first place by calling the attention of the medical profession to the anomalies of the septum as a causation of the pathological condition of the nasal mucous membranes, and in the second place, by introducing a number of simple surgical measures for the removal of such existing anomalies, as spurs, angular deviations, exostoses, etc. I need only refer to the introduction of the saw by Dr. Bosworth, the use of the surgical drill and trephine by Goodwillie, Jarvis, Curtis, and others, and finally the ingenious and simple operation of the late Dr. Asch for the correction of such septal changes as were beyond effective treatment by the methods just referred to. All these procedures have been adopted on the continent. The electrical trephine is used abroad almost more than in this country, and its use has even been extended to aural and general surgery. Its introduction on the continent was due to an incidental conversation with Prof. M. Schmidt of Frankfurt while visiting his clinic in 1891. Professor Schmidt showed me some cases of deviation and exostosis which he had been treating by electrolysis. On investigation I found that the removal of a small spine took several weeks and appeared to be accompanied with unnecessary complications and inconveniences to the patient. I informed Professor Schmidt that the American rhinologists in such cases made use of an electric trephine and that the patient was completely cured by these means in a very short time and without any or, at least, with trifling danger. Dr. Spiess,[1] the associate of Professor Schmidt, adopted the suggestion and published in the *Archiv für Laryngologie*, an article upon the use of electric trephines, burrs, and saws for the removal of spurs, deviations, etc. There is hardly a laryngologist to-day in even the smallest towns of Europe who is not equipped with a complete electrical outfit, the development of which is a product of American ingenuity. Thanks to the efforts of the late Dr. Asch, the importance of correcting deviations of the nose has been brought to the notice of the general practitioner, and the correction of septal deviation to-day is a recognized and important operation. No doubt, however, most rhinologists have met cases which are not fit subjects for the various operations which have been proposed, a number of which, too, have been almost superseded owing to the unsatisfactory results which they give in their application. I refer, for instance, especially to the transfixion operation with the needle, the punch operation, etc. It is not, therefore, the object of this paper to recommend submucous resection of the septum, in opposition to the other recognized operative procedures, but to recommend the operation for those cases in which experience has led us to know beforehand that the results obtainable by the simpler methods, as the use of the saw, the drill, or even the "Asch" operation, are not good. Doubtless most of the gentlemen who have employed the Asch operation will have met some cases in which it does not cure the conditions permanently, or even if during the treatment, and the employment of the tubes in the after-treatment, the deviation appears to be corrected, a gradual return of the septum to its former deviated position occurs within a few weeks or a few months. It is these cases especially which are absolutely cured by the submucous resection.

Before entering upon a short description of the operation, some digression in reference to the classification of anomalies of the septum may be permissible. That the untold irregularities almost prevent an exact scientific classification is almost obvious. If we follow the customs of the anatomists to include under deviation the many protuberances of the septum running either in a vertical or horizontal direction, involving either part or the whole of the septum, that is the large group of exostoses and ecchondroses, we may in a broad way divide the anomalies of the septum into three groups: (1) Exostoses and ecchondroses, that is circumscribed deviations from the median line; (2) Displacements of the whole or greater part of the septum itself from the median line in the course of either the sagittal or the horizontal axis, or in both planes; (3) Displacements of the septum combined with various forms of exostoses. It is hardly necessary to state that the anomalies of the first group, or many of the third group—as for instance, angular deviations with considerable thickening at the point of deviation—may be excluded from our consideration, as these anomalies are more easily remedied by simpler operative procedures. It is therefore the anomalies of the septum comprised in the second group which are to be considered in connection with the submucous resection. The displacements referred to in the second group have usually been divided into the C-shaped deviation, or in the compensatory form, the so-called S-shaped variety. Usually these anomalies are more rounded, scoliotic in character, the curvature either involving the greater part of the septum or confined to a portion of it. Occasionally, however, a combination of the C- or S-shaped deviation, occurring either in one plane or a number of planes, may cause anomalies of most irregular shape. The recognition of these more irregular forms of deviation, belonging to the third group is important, as in some of them the curvatures of the septum may be so great as to exclude the use of the saw, chisel, or trephine, so that at times even

*Read before the Academy of Medicine, Section on Laryngology, October 28, 1903.

apparently angular deviations, which generally are amenable to the saw or drill, may necessitate a submucous resection in order to accomplish a successful result. Although the resection of the septum had been recommended by Hartman[1] and Petersen[2] in 1883, it is really to Krieg of Stuttgart that the credit belongs of having most systematically described and recommended the submucous resection for the purpose of correcting and removing successfully septum-deviations. The principles involved being the same, it would be idle for me to take up your time in describing the various procedures employed by Petersen, Hartman, Krieg,[3] Cholewa,[4] and others. Frequently the various procedures are only variations of slight moment, either the use of a chisel, saw, or in the use of the cautery or knife for the incision of the mucous membranes. Krieg published his method in 1886. My attention was first called to the operation by Dr. Frederic Lange, who in principle followed the method of Krieg, employing, however, the modifications of scooping out the cartilage with a sharp spoon after having separated the mucous membrane. In some cases the use of the sharp spoon gives excellent results and abbreviates the length of the operation. My personal experiences with the submucous resection dates from 1888, and I shall take the liberty of briefly describing the methods which I have generally followed:

In the earlier cases, the operation was usually performed under general anæsthesia, later on almost entirely under local narcosis. Since the introduction of adrenalin, a combination of a weak cocaine solution and adrenalin has usually sufficed in most cases. Instead of employing the sitting posture, as recommended by Krieg, I have usually placed the patient on the table on his back with the head slightly raised and the chin depressed, the head slightly turned away from the deviated side. The nostrils being held back by retractors, an incision slightly convex is made through the whole length of the mucous membrane as near to the point of greatest convexity as possible and only through the mucous membrane. Care in not cutting through the cartilage at the first incision is of value in enabling a more rapid separation of the mucous membrane from the cartilage. The mucous membrane is then held back by a small sharp hook, and the cartilage, after being exposed as far as possible, is nicked and then gradually separated from the mucous membrane on the other side. After the cartilage has been freed as far as possible, especial attention being paid not to dislocate it, an incision above is made parallel to the ridge of the nose in order to prevent an external deformity, a second incision made below, and the cartilage finally dissected out posteriorly; the first piece removed usually embraces the greater portion of the protuberating cartilage. The still protruding pieces must be removed piece by piece, working from before backward, and, if necessary, even removing the bony portion with a small bone forceps. An occasional revision and replacing of the mucous membrane is the best guide as to the the amount which must be removed. In suitable cases with large noses and anterior deviations, the operation may be finished rapidly, in some cases twenty minutes sufficing for the whole operation; in more difficult cases the operation may take as long as two to two and a half hours. After the cartilage has been removed the mucous membrane is carefully replaced; if it has been torn and forms a flap, one or two sutures may be added to keep it in place. The nares are then lightly packed with gauze and the patient kept in bed for a day or two. Ice applications over the nose and change of dressing every twenty-four hours for two or three days is usually the only treatment required. After that, the patient may be discharged; no further *after-treatment* being necessary except the use of an ointment or an oil spray to prevent formation of crusts until the mucous membrane has regained its normal condition.

The description of the operation refers to ideal cases in which a complete subperichondral resection is actually accomplished. Sometimes it is impossible to obtain an absolutely perfect result from the standpoint of the operator. Smaller and larger perforations are likely to occur partly on account of the difficulty of the technique in the separation of the delicate mucous membrane from the cartilage, partly owing to the fact that the mucous membrane of the concave side is frequently atrophied and so thinned that it tears in the separation, or occasionally sloughs away after a few days. The borders of the perforations in those cases in which a perforation has been unavoidable, however, always epidermize so that the perforation itself does not in any way produce a further inconvenience. The perforations vary in form from a mere slit to an oval or rounded opening. A further cause for possible perforations are the continual hemorrhages during the operation which interfere greatly with the stripping of the mucous membranes from the cartilage. It has always been my experience that the perforations are caused by the endeavor to take away a little more than is necessary, and a lack of patience in shelling out the small pieces of cartilages that remain between the layers of the mucous membrane. The use of a scoop instead of scissors hurries the operation, but frequently entails loss of mucous membrane which adheres to the cartilage, especially in the posterior portion where we are guided more by touch than sight. The use of the electric head-illuminator is almost indispensable in the removal of the posterior portions of the cartilage, and I have, therefore, usually performed the whole operation under artificial illumination. The use of adrenalin decidedly improves the chances of avoiding perforations. Complications, such as secondary hemorrhages, I have never observed, and the necessary severe manipulation of the mucous membrane during the operation usually helps to prevent loss of blood after the operation. My experience in this respect differs somewhat from that of Krieg and others who have observed severe secondary hemorrhages. The selection of suitable cases in operating only upon youthful subjects and patients otherwise perfectly healthy, is the best safeguard to the avoidance of severe hemorrhages. I have never observed sepsis or a complicating otitis. Occasionally during the first or second week a follicular tonsillitis occurs, probably in not more than 5 per cent. of the cases. I make it an invariable rule to warn the patient of the possibility of an attack of tonsillitis. In some cases the remaining portions of the septum are slightly swollen for a few days, so that the patient does not obtain the desired relief until a week or two after the operation. It is also advisable to inform the patient before the operation of the possibilities of an ensuing perforation, as it is impossible to tell beforehand in which cases a perforation may be prevented. In regard to perforation, for those laryngologists who hold the opinion that perforations are a detriment and a subsequent annoyance to the patient, it is advisable to refrain from the operation, as statistics show frequent perforations in cases of submucous resection of the septum. For my part, however, I have absolute conviction that a perforation is harmless. In those rare cases, for instance, in which the vomer is deviated to such an

extent that even after the removal of the anterior deviation breathing on the narrowed side is still interfered with, relief can only be obtained by producing a perforation, even if technically it can be avoided.

Contraindications for the submucous operation are the same as for other nasal operations: Atrophic conditions of the mucous membranes, systemic disturbances, nephritis, etc., or advanced age which might endanger the life of the patient through the ensuing hemorrhage. It is not advisable to perform the operation on children under ten, as the septal changes during that time of life might render a too early operation futile. The most suitable range is from ten to thirty years. It is hardly necessary to formulate the indications for the submucous resection. The operation will be indicated in all cases of scoliotic conditions of the septum, and those forms of deviations which are not amenable to the usual operations by means of the saw, chisel, or electric drill, etc. A broad angular deviation, for instance, with thickening of the protruding septum may be far more easily operated on by the Bosworth saw, or the use of the electric trephine. The results obtained when some care is considered in the selection of the cases, are uniformly excellent. The remaining layers of the mucous membrane gradually attain a rigidity which almost forms a new septum. No doubt a production of cartilage from the chondroblasts of the perichondrium, which is intimately connected with the mucous membrane is the anatomical explanation for the formation of such a rigid partition. The only apparent drawback to some rhinologists possibly might be the frequency of perforations. Heyman,[5] in his handbook, reports perforations in nearly 70 per cent. of the cases. In my experience, which embraces about seventy-five cases, the statistics are much too high, as I have met with only about 20 per cent. of perforations. An ensuing perforation, however, in my judgment, is perfectly harmless. In healthy individuals the loss of that part of the mucous membrane neither affects the patient subjectively, nor does the nasal mucous membrane show any further changes on inspection by the physician. I have no doubt that with care in the selection of cases, and in a more universal adoption of the operation by the profession, by a choice of proper instruments, and improvements in technique, it will be possible to overcome even this apparent draw-back, an unintentional perforation of the septum. I have referred to unintentional perforations, because there is one condition in which a submucous resection may be performed which necessitates a perforation. I refer to those cases which are not as rare as was at one time supposed, the complete displacement of the vomer and quadrangular cartilage, accompanied in such cases by atrophy of turbinated bodies on the deviated side, and complete atresia. Some patients under this condition suffer annoyances because they have not the subjective feeling of air through the affected nostril. If the annoyances are so great as to warrant an operation, the patient can only be relieved by a perforation of the septum for obvious reasons.

A natural question in connection with a formulation of more precise indications is what cases should be selected for the submucous resection. That all those cases which can be operated by simpler measures with the knife, saw, chisel or drill, for instance, should be excluded, is obvious. A more important question which should be considered, is, should we, in cases of deviations not amenable to the methods above mentioned, consider the orthopedic operations, as the "Asch" operation, for instance, or should we enlarge the scope of the submucous resection at the expense of orthopedic surgical interference? As the object of this paper is merely to recommend an operation which has not been as widely adopted as it deserves, I would rather leave it to the future and to the judgment of the individual to decide this point.

That the results of the submucous resection are uniformly excellent, that an after-treatment becomes entirely unnecessary, the operated septum usually taking care of itself, and that last and most important, that the cure is permanent, a closer examination of the seven cases which I had the honor to present to you will clearly prove.

**Adenoids in the Adult.**—The paper of J. E. Logan is summarized in the following propositions: (1) The necessity of the early recognition of adenoid growths in children by the general practitioner. (2) Prompt removal is called for when so extensive as to interfere with the development of the child, and especially when the patient has been exposed to any of the exanthemata. (3) When present in patients suffering from the above eruptive diseases, attention must be directed to proper disinfection of the pharyngeal vault. (4) In patients exhibiting enlarged faucial glands there generally exist hypertrophies in the vault—the reverse condition does not always obtain. (5) Hypertrophy of the pharyngeal glands in adults is *not* a rare condition, and as a rule it is dependent upon pathological changes during childhood, and not developed after puberty. (6) Operative interference is warranted in every instance not only to relieve existing dependent conditions, but to prevent impending complications.—*Laryngoscope.*

**Principles in Drainage.**—C. H. Mayo holds that aseptic operations in regions rich in lymphatics, where the lymph circulation is but little disturbed, will not require drainage—as ligation of vessels in the neck, Alexander's operation and hernias in the inguinal region. Aseptic operations in these regions in which the lymph system is removed require capillary drainage from four to six days as auto-drainage is temporarily abolished. In regions rich in lymphatics, where operations for septic conditions must necessarily be made, we open fresh areas for absorption of toxins, and our endeavor should be to use upon the incised surface strong antiseptics, such as carbolic acid, followed by alcohol, chloride of lime as a caustic, or in mild cases glycerin to prevent or inhibit the action of the absorbents, and maintain the disease as a local infection. This is markedly shown in operations for the removal of bone necrosis. In aseptic operations of the abdomen involving considerable bruising or denuding of the peritoneum the pelvis should be elevated by raising the foot of the bed, the gravity acting as an aid to auto-drainage, the peritoneum being capable of absorbing from 3 to 8 per cent. of the body weight in an hour. In septic diseases, on the contrary, drainage is secured by elevating the head of the bed and the upper extremity of the patient to gravitate to the pelvis, whence delivery may be made through glass tubes. The diseased or septic focus should also be quarantined by a gauze pack through a separate incision, should the condition of the patient warrant the increased operative interference —*The Medical Herald.*

## CAISSON DISEASE AND DIVER'S PALSY.

IN this age of engineering, and especially of bridge building and tunnelling, the use of the caisson is universal. Divers, too, ply their calling much more frequently than even a few years ago. Therefore, it is only natural that investigations should take place to probe the causes and to devise measures of prevention of the affection which so often attacks men who work in those steel cylinders under the water, and out of which the water is kept by means of compressed air. Diver's palsy is a condition which has been known as long as divers themselves have existed, many thousands of years, and resembles in most of its symptoms caisson disease.

Mr. Leonard Hill, lecturer on physiology at the London Hospital, and Mr. J. J. R. Macleod, professor of physiology, at the Western Reserve University, Ohio, have been for some time conducting researches into the physiology, pathology, and cause of caisson illness and diver's palsy, and have published the results of their experimental study in the *Journal of Hygiene*, October, 1903. The article —valuable as it is—can be commented upon, but somewhat briefly here, owing to lack of space, and caisson disease will be only considered. Caisson disease and miner's palsy never attack men when under pressure.

Pol and Watellel,* who went down into a caisson themselves, in 1884, had sixty-four men employed in a caisson on the banks of the Loire at +3¼ atm. The men were compressed in fifteen minutes, worked for a four-hour shift, and were, according to the rules, decompressed in thirty minutes.

The physiological effects observed in compressed air were very slight—pains in the tympanic membrane—relieved by opening the eustachian tube; slowing of respiration and diminution of thoracic expansion; slowing of the pulse; increase of urinary secretion; a feeling of resistance to movement, owing to density of the atmosphere; inability to whisper attributed to the resistance of the compressed air to the finer muscular movements of the tongue. On decompression Pol and Watelle felt a lively sensation of cold and a certain degree of breathlessness, while the pulse was accelerated. The cold is due to expansion of the air.

As to the pathological effects these same authors said: "There were forty-seven men out of sixty-four who stood the work in caissons more or less well; twenty-five were discharged owing to sickness; two died. The slighter attacks were fourteen, and the serious attacks sixteen in number.

**Ann. d'hygiene et de méd. légale*, 1854.

"With regard to the manner in which compressed air exerts its injurious influence on animal life, Pol and Watelle are of the opinion that pulmonary and cerebral congestion are the chief results of compressed air. Just as a lowered atmosphere pressure brings blood to the exterior and causes hemorrhages, so does compressed air congest the viscera." The brain and spinal cord, according to Babington, shut up in their osseous cavities, are not able, like other elastic parts, to accommodate themselves quickly to changes of pressure. Bouchard advanced this extraordinary theory. As the gases of the intestine are compressed, the abdominal wall becomes concave, and as the abdominal wall resists this distortion it converts the abdomen into a kind of cupping-glass. This leads to congestion of the abdomen during compression, and the reverse on decompression. Dr. A. H. Smith is the principal exponent of the mechanical congestion doctrine. He deduced "the law that under high atmospheric pressure the centers will be congested at the expense of the periphery . . . and that firm and compact structures will be congested at the expense of those more compressible."

Messrs. Hill and Macleod state that Paul Bert was the first to point out the real cause of caisson sickness. He conducted a series of remarkable experiments in 1878, by which he proved that the true cause of the affection is the effervescence of gas in the blood and tissue juices. Others, such as Hoppe, François, Rameau, and Bacquoy, had drawn the same deductions, but had generally put this cause down as subsidiary to mechanical congestion.

Messrs. Hill and Macleod have themselves carried out a series of experiments, the results of which confirm Bert's conclusions, and in addition they present considerations drawn from the results of their own experiments and investigations. Snell has a strong belief in the good effects which follow free ventilation of caissons. He says, "An increase of $CO_2$ from .04 per cent. to .1 per cent. at thirty pounds pressure is the forerunner of much illness. Messrs. Hill and Macleod say that as matters stand at present it is not easy to explain Snell's ventilation results, and it is urgently required that they should be confirmed.

Increased rate of ventilation did not seem to affect the writers' animals, in the experiments undertaken, with regard to the dangers of decompression. They concluded, from the records of caisson sickness and from their own experiments, that the men selected for high-pressure work should be small men, of spare and wiry habit, not older than twenty to twenty-five. The men should be total abstainers and abstemious in all their habits. The men should be tested at low pressures first, those who suffer from symptoms should be discharged. The following may be considered safe rules for working: The longer the shift, the greater is the saturation of the body fluids with gas, and the slower, therefore, should be the decompression. The higher the pressure, the shorter should be the shift, and the longer the decompression. The following times are suggested as safe for working in caissons:

| Atm. | Lbs. | Shift. | Dp. |
|---|---|---|---|
| +2..... | 30 | 4 hrs. | 30′–1 hr. |
| +3-4 ..... | 45–60 | 4 hrs. | 1–2 hrs. |
| +5..... | 75 | 1 hr. | 1–2 hrs. |
| +6–7 ..... | 90–105 | 30′–1 hr. | 2 hrs. |

To prevent men breaking the rules, the decompression chamber should be provided with one cock only, which will allow decompression to take place in the given time. A separate lock should be provided for the rapid passage of material. The decompression chamber must be artificially warmed, so that the temperature does not fall below 60° F., and it must be thoroughly ventilated during decompression. The ventilation of the caisson or diving apparatus should be very free, and the temperature of the air should be about 60° F. The men should remain quiet for an hour or so after decompression and be recompressed on any sign of sickness. Paul Bert recommends that oxygen be supplied to the decompression chamber to hasten the diffusion of nitrogen. This, think the writers, is no doubt a means by which the period of decompression might be shortened, but it introduces the danger of oxygen poisoning. They are of the opinion that by proper choice of men and regulation of the shift and decompression period, work could be carried on without loss of life at a depth of even 200 feet, *i.e.* about 7 atm. or + 100 pounds pressure.

Summarizing some of the chief points in connection with caisson sickness, the writers say: The circulation is unaffected mechanically by compressed air. The cause of caisson sickness is the escape of gas bubbles in the blood-vessels and tissue fluids on decompression. An animal exposed for four hours to 8 atm. of air and quickly decompressed is like an opened bottle of soda water. The fluids of the body generally effervesce. The varying symptoms of caisson sickness are due to the varying seat of the air emboli. Young men escape caisson sickness, sowing to the elasticity of their tissues and greater facility for collateral pathways of circulation. Animals can be safely exposed to 8 atm. of air for 4 hours, if 2 hours be spent in gradual decompression. Such experiments can be safely repeated three times a week.

The above information respecting caisson disease is of much practical value, as well as of being of scientific interest. There is no country in which these contrivances are so largely used as in America, and if measures can be put into force whereby sickness consequent upon staying in compressed air for some hours, may be avoided or even lessened, the cause of humanity will have been greatly helped. The conclusions arrived at by Messrs. Hill and Macleod are founded upon the results of careful experiments and investigations, both by themselves and others, and if the suggestions made in the *Journal of Hygiene* are carefully followed, there would seem to be no reason to doubt that the conditions under which workers in caissons live would be greatly improved.

---

## SUDDEN DEATH AND STATUS LYMPHATICUS, ANÆSTHESIA AND INFECTION.

In the *Bulletin of the Johns Hopkins Hospital* for October, Dr. George Blumer discusses the relation of the status lymphaticus to sudden death, death under anæsthesia, and in connection with infection. Sudden death in all three classes of cases is important and interesting from the professional and medicolegal standpoints. Thus, a number of cases are on record in which nurses or relatives have been accused of suffocating or fatally maltreating infants, when the autopsy has revealed status lymphaticus as the cause of death. Noted by Bichat in 1723, the association of sudden death with enlargement of the thymus was revived in 1888 by the work of Grawitz in Germany, and Jacobi in this country. Paltauf and the Vienna school have shown that the thymus enlargement is only part of a general lymphatic hyperplasia. The school named believes that it is possible to diagnose the status before sudden death reveals it. Escherich states that they usually have a pale, thin skin, a pasty complexion, and a good pad of subcutaneous fat. Frequently rachitic or scrofulous signs are present. The superficial neck glands, especially those of the neck and axilla, are enlarged. There is hypertrophy of the tonsil, of the circumvallate papillæ of the tongue, and the pharyngeal lymph apparatus (adenoids). The spleen is often palpable. Daut adds that a percussable thymus may develop later. And Ewing's work strongly suggests that an increase in the lymphocytes of the blood is in all likelihood present. The author classifies the recorded cases under the headings, cases found dead in bed, cases presumably of cardiac origin, those presumably of respiratory origin, and those presumably of nervous origin. It is a question, he thinks, whether many of the cases of "overlying" of infants would not be found to be deaths from status lymphaticus if investigated. Cases presumably of cardiac origin will comprise those cases in which the sudden death is not preceded by respiratory disturbances. Most cases are preceded by such disturbances, namely, by the symptoms of "thymic asthma," which there is no doubt has been confounded by some observers with laryngismus stridulus; though most students agree that there is no connection between the conditions, and Lange states that the asthmatic paroxysm differs from the stridulus in the regular sighing respiration present throughout in the former. Blumer's cases, however, showed this not to be true, and that the asthmatic picture is not uniform. Some cases die with signs of suffocation without asthmatic seizures. Laub's cerebral form consists of coma, or perhaps epileptiform convulsions, sometimes glottis cramp or cerebral vomiting, usually albuminuria (but no casts), with death in a few (at most eighteen) hours.

The last few years attention has been called to death under anæsthesia in association with status lymphaticus. Almost all observers agree that in these cases death is due to cardiac failure, most of the histories showing clearly that the respiration persisted after the heart ceased. The earlier writers considered chloroform specially dangerous in these cases, but recent experiences have shown deaths under ether and the A. C. E. mixture. These deaths have occurred at all ages and no distinction as regards sex seems possible. Finally it would seem as though two classes of patients with status lymphaticus are especially liable to sudden death, those with goiter (simple or exophthalmic), and those with adenoid vegetations.

The microscopical changes observed by Blumer

were uniform, and consisted in general of hyperplasia of the lymphoid elements of the thymus, at times associated with proliferation of the endothelial cells along the trabeculæ; and general hyperplasia associated with focal changes in the lymph nodes, Malpighian corpuscles of the spleen, tonsils, and intestinal lymphatic apparatus. The lesions very closely resemble those seen in various infections, and differ only in degree.

Bacteriological investigations resulted only in showing that some factor other than bacterial infection must be held responsible for the lesions in most cases of the status lymphaticus.

Discussing the causes of sudden death, two main lines of theory have been advanced to account for the occurrence, mechanical and toxic. The mechanical theories assume that pressure on the trachea is the cause of death, and its supporters point to the very narrow space (2 cm.) in children between the manubrium and the vertebral column, and the fact that throwing back the head greatly increases the pressure on the trachea. The opponents show that it requires a pressure of 180 grams *ad minimum* to produce such compression, while the enlarged thymus weighs only about 50 grams. Others suggest that pressure on the large vessels is the immediate cause of death. And still others name the pneumogastrics and phrenics as the compressed structures. Blumer, however, expresses himself in favor of the view of Escherich, who considered that the cause of death might be a toxæmia. Blumer says: "We would therefore advance the hypothesis that the condition which is present in the status lymphaticus is one of lymphotoxæmia. It is not necessary to assume, we think, that the toxæmia is constantly present; in fact, the clinical pictures are more readily explained by the assumption that it is intermittent. We would suggest that individuals who are subjects of the status lymphaticus are born with an instability of the mechanism regulating the 'horror autotoxicus,' at any rate so far as the lymphatic apparatus is concerned, so that they are subject to intermittent attacks of lymphotoxæmia which may lead to reflex nervous phenomena of various kinds, or may cause death from cardiac paralysis. During the attacks of lymphotoxæmia such individuals are especially susceptible to the action of bacterial or chemical poisons, and also to physical and psychical shocks, which at these times may cause their death under circumstances which would be trivial to a normal individual."

The author concludes that the condition known as the status lymphaticus is a definite pathological entity. It may be associated with sudden death, prabably as a result of lymphotoxæmia; alone in some cases, or as the result of the action of toxic, physical, or psychic injuries, which are rendered much more powerful than usual by the predisposing action of the lymphotoxins. In some cases the sudden death is certainly due to asphyxia from pressure of the enlarged thymus on the trachea. The subjects of the status lymphaticus can be recognized clinically in some cases. The paper concludes with the detailed histories and the bacteriological and the pathological findings in nine cases.

## THE INSANE CONVICT.

In his address before the National Prison Congress, Dr. H. E. Allison, Superintendent of the Matteawan State Hospital, says that there is room for improvement in the treatment of our prisoners, but that the improvement can only come about through an intelligent study of the convict himself. Our attention should not be directed merely to his crime. The questions to be determined before any proper disposition can be made of the convict, or his reformation attempted, relate to his personal characteristics—his personality. The whole substratum which underlies our probation and parole laws concerns the individuality of the convict in each and every case.

We must understand his peculiar nature before we can act intelligently. We must know where he stands, physically, mentally, and morally. Unless we have such knowledge we cannot certify as to his fitness for conditional release. We can confine him in prison, but we cannot benefit him. Prisons should not be mere places of detention. They should lessen the prevalence of crime, if possible. For the habitual and incorrigible offender they should offer provision for prolonged, perhaps for perpetual, detention.

The officials in every prison should, therefore, know intimately the character and mental responsibility of every inmate. Our prisons and reformatories would do much better if the insane and idiotic were placed in other suitable institutions. Though our laws provide that such persons have no responsibility for crime, nevertheless, many such persons are sent to prison, most of whom have marked criminal tendencies, and become recidivists of the most pronounced type.

It should be the duty of the prison physician to recognize such cases and to secure their transfer to other institutions where they can be cared for permanently, or until their release can be safely allowed. Cases of this kind have been known to pass repeatedly through the courts without any question of their mental condition being raised, or any obstacle being interposed to their frequent passage in and out of the prison doors. Some are sentenced with few preliminaries, the accused's plea of guilty being accepted, and nothing being ascertained in regard to his antecedents. In other cases, the insanity of the prisoner has been decided by a jury not to exist.

In face of the great attention which is now being given to the question of the accurate identification of the criminal, it is surprising that so little attention is paid to the insane convict, who should not be released merely because his term expires, as he is almost certain to commit crime again. The general insane hospital is not a suitable place for the insane convict, but it is a better place than the prison, and his relegation to the insane hospital may lead to the erection of a special hospital for him, as has happened in New York. As the term of the insane convict draws to an end, if his insanity continues, the hospital superintendent should be empowered to communicate the facts to a court of record, and, after suitable examination, the indefinite retention of the person should be authorized on the ground of his insanity.

### Is Scarlet Fever a Protozoan Disease?

On December 15 Dr. Frank B. Mallory of Harvard University announced to the Boston Society of Medical Sciences that he had demonstrated a protozoan in the cutaneous lesions of four cases of scarlet fever which had died in the eruptive stage. So far as the data are at our command, Dr. Mallory describes the stages of development of this parasite as similar to those of the malarial organism. It is, however, about one-third larger, and in the rosette stage contains twice as many segments. Its development in the human body is asexual. Whether a sexual development also occurs, as with the malarial organism, has not as yet been determined. Dr. Mallory does not claim that facts have been adduced which prove the bodies described by him are in reality protozoa, or that if such is the case they are the causative agents of scarlet fever. He states, however, that in his personal opinion this is so.

It has been apparent for some time that endeavors to isolate the causative microorganism of scarlet fever from the blood of patients suffering with this disease were likely to prove indefinitely futile. Streptococci are the only microorganisms which have been isolated from such blood with a sufficient regularity to warrant serious consideration in this connection. Streptococci have also been obtained from the cutaneous and throat lesions of this disease, and likewise from the various serous effusions which are at times present as complications. Notwithstanding these facts, the foremost investigators of the world are to-day divided as regards the etiological relation of the streptococcus to scarlet fever. Considering our advanced methods of research, our present knowledge of the biology of microorganisms, and the large amount of work which has been done in the bacteriology of scarlet fever, it is but reasonable to assume that if the streptococcus were the causative agent the fact would have been established before now.

In this state of affairs, Dr. Mallory's attempt to open up a new field is especially commendable. The thought that scarlet fever might be a protozoan disease cannot be said to be entirely new. So far as we are aware, however, Dr. Mallory's demonstrations are the first which have appeared to confirm such an opinion. At the present writing it is impossible to say how far his demonstrations will carry conviction to the minds of others. Whether or not his opinion be true, it is certain that coming from such an authority they possess weight and cannot fail to stimulate research in this particular direction.

---

### The Distribution of Insanity.

Dr. W. A. White of the Government Hospital for the Insane at Washington, D. C., gives a very interesting account of the "Geographical Distribution of Insanity in the United States." He takes the ground that "the proportion of insane is highest where we find the greatest congestion of population, and therefore where the stresses incident to active competition is most severe." This view is one generally accepted by alienists the world over, and is evidently a fundamental causative influence of mental alienation. While hereditary predisposition to insanity must be recognized as a leading factor in determining results, he believes that a quiet life is a sufficient guarantee against mental breakdown. On the other hand, excessive perturbation due to business anxiety, excessive study, grief, domestic trouble, loss of property, love, or political excitement, are well recognized exciting causes of the disease.

There is also an acquired predisposition due to alcohol and a certain disease, and alcohol and disease act with most effect in crowded populations, where the struggle for income is bitterest. With the Indian, it is noted, insanity is of rare occurrence. This is not because he is not "afflicted by the diseases and vices of civilization," but because he lives an outdoor life, and being "careless, slovenly and improvident, he does not worry" and is free from "mental stress."

Regarding the negro, Dr. White says, "he remains sane despite his unhygienic surroundings so long as he remains in the country, his "natural home," but fails when, thrown upon his own physical and mental resources, he enters the strife for existence in Northern cities. "As soon," says Dr. White, "as the negro goes North and enters into active competition with the white, who is mentally his superior, he succumbs to the unequal struggle. So in Georgia, where we find the greatest number of negroes, there was 1 insane negro to 1,764 of the colored population in 1880, while in New York the ratio was 1 to 333, or almost exactly the same ratio as for the white population."

In the industrial States of the East insanity is very common. In Massachusetts, for example, there is 1 insane person for every 348 of population, while in Virginia the proportion is 1 in 512 of population, in Arkansas 1 in 939, and in Texas 1 in 950. In the United States, omitting the Southern States, there is 1 insane person to each 542 of population, but in the Southern States the proportion is 1 to 1,277. "In Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Texas, and Virginia," says the writer, "we find the ratio of colored insane 1 to 1,277, while for the whites in the same territory it is 1 to 456. In other parts of the United States the ratio of colored insane, as is shown by the Tenth Census, was 1 to 542, while for the whites it was 1 to 520. The ratio of colored insane in the United States, minus the Southern States, is, then, almost exactly the same as the ratio for the white insane."

These facts, although in the main well accepted ones, are of extreme interest in proving the ill-effects of mental strain in connection with the growing and exacting requirements of advancing civilization. It is the fret and worry of the work rather than the work itself that causes the breakdown.

---

### The Prompt Collection of Fees.

Dr. M. A. Tate of Cincinnati gives, in the *Lancet* and *Clinic*, some very sensible advice to physicians regarding the prompt collection of fees which must necessarily appeal to the many practitioners who at this time of the year are looking over their doubtful accounts. Says Dr Tate:

"One of the first things I made up my mind to attend to, after I entered the practice of medicine, was to try to collect my bills. This I have been fairly successful in doing, and I follow out this plan. My bills are sent out the first of the month following services rendered. I invariably do this for the following reasons:

"First, if there is any misunderstanding as to the amount, it is fresh in our memories and we can straighten it out with satisfaction and dignity to all concerned.

"Second, I know where my patient lives.

"Third, patients pay quicker, because they have not had time to lose all the gratitude that was born in them while they were sick.

"If I know a patient is a dead beat, then I respon to the call upon one condition, and that is the mone

in advance, or I tell them it is their privilege to seek any of my neighbors."

And why should not this advice be followed by the thousands of hard-worked doctors who get cheated at every turn. A fee in the hand is always worth two in the book.

### Light Therapy in Eye Diseases.

Light as a therapeutic agent seems destined to widespread use. One of the most recent moves in this direction looks toward its employment in the treatment of various eye diseases. H. Strebel (*Klinische-therapeutische Wochenschrift*, November 8, 1903) has shown that the ultraviolet rays are transmitted much more readily by the tunics of the eye than by the skin and mucous membranes. This was demonstrated by experimentation with the eyes of certain animals. The ultraviolet light was thrown upon a screen and the different tunics interposed in the path of the rays. The intensity of the shadow thus produced upon the screen showed the degree of transmission which the tunics possessed. Also live rabbits were taken and their eyes exposed to the action of the rays. Thus it was shown that typical reactions are produced in the cornea, iris, and conjunctival mucous membrane. The employment of the rays in the treatment of various forms of conjunctivitis, keratitis, and iritis is thus suggested. Although the rays may be made to reach the retina, it is questionable whether they can be utilized in the treatment of the affections of this membrane, as detachment of the same might result from their application. Thus far the work has been entirely experimental in character, no therapeutic tests having been made.

## News of the Week.

**An Antituberculous Bacillus.**—At the regular meeting of the New Haven Medical Association December 16, Dr. Stephen J. Maher read a paper on "Some Investigations of Bacterial Treatment of Tuberculosis." Six years ago he found that the last microorganism to remain alive in some samples of milk from a tuberculous cow was a sporogenic, liquefying, facultative-anaërobic bacillus. Later he learned that this bacillus could be injected into animals without harming them, and was closely akin to, if not identical with, Bacillus Mycoides III (Conn.). He reported in his paper that he had injected pure live cultures of this bacillus into nearly one hundred patients suffering from pulmonary tuberculosis. In closing, he emphasized the following points: (1) This bacillus can with safety be injected alive and in pure culture into the human system. (2) After its injection it remains alive in the human system often for weeks, and does no other harm than occasionally to cause slight suppuration. (3) After its injection it causes a variable febrile reaction which is never serious. (4) After its injection it has been found in the urine, blood, and sputa. (5) After its injection into the groins of persons suffering from tuberculosis there is often a subjective sense of local reaction at the site of the tuberculous lesion. (6) After its injection into the connective tissue about a tuberculous fistula in ano a marked improvement, even to the closing of the fistula, was followed. (7) A cure of tuberculous otitis media in several instances followed a local injection of cultures. (8) After its application on gauze or cotton packing to sinuses leading from carious bone supposedly tuberculous, such sinuses have healed with surprising promptness. (9) Its hypodermic injection into patients suffering from tuberculosis of the lungs, has been followed in many cases by relief of such symptoms as cough, fever, night-sweating, wasting, anorexia, diarrhœa, and hemorrhage. (10) Its instillation into the open tuberculous pleural cavity has caused the drying-up of a purulent discharge that was resistant to ordinary methods of treatment. (11) Its hypodermic injection into consumptive patients has in several demonstrable cases been followed by the apparent cure of the disease. (12) As a valuable scavenger of the tuberculous human system, this bacillus claims the interest of the medical profession for the further reasons that it grows in acid or alkaline media, that its product is alkaline, that it grows in the presence or absence of air, that it feeds only on dead matter, that it grows more quickly and has more vitality than the ordinary pus-producing germs, and that its introduction into the human tissues is followed by a marked diminution of the number of ordinary pus-producing germs present in the body. (13) Some, as yet, incomplete, investigations would seem to show that this bacillus is not without beneficial effect in other pathological conditions than tuberculosis. In conclusion, Dr. Maher said that while he realized that many of his statements needed confirmation by other bacteriologists, and that it was probable that some of them would fail of such confirmation, still he had felt that it was time to invite his brother physicians to look at the vision that had been before his eyes for so long.

**Ohio Valley Medical Association.**—At the annual meeting of this society, held at Evansville, Ind., November 12 and 13, 1903, under the presidency of Dr. Benjamin L. W. Floyd, the following officers were elected: *President*, Dr. A. M. Hayden of Evansville, Ind.; *Vice-Presidents*, Drs. J. W. Stone of Henderson, Ky., C. T. Hendershot of Cannelton, Ind., and August Sohachner of Louisville, Ky.; *Secretary and Treasurer*, Dr. A. J. Leiber of Henderson, Ky. The next meeting will be at Evansville on November 9 and 10, 1904.

**The Seventh International Congress of Otology** will be held at Bordeaux on August 1-4, 1904. Those intending to take part in the work of the congress are requested to send the subscription of 25 francs to the treasurer, Dr. Lannois, rue Emile-Zola, 14, Lyons, France, before May 1; and anyone purposing to read a paper at one of the sessions is requested to send the title with a brief abstract to the secretary-general, Dr. Lermoyez, rue la Boétie, 20 bis, Paris, on or before the same date. The official languages of the congress will be English, French, German, and Italian. The following subjects have been selected for formal discussion: (1) "Choice of a simple and practical acoumetric formula," opened by Politzer, Gradenigo, and Delsaux. (2) "Diagnosis and treatment of suppuration in the labyrinth," opened by Brieger, v. Stein, and Dundas Grant. (3) "Technique of operation and after-treatment of otogenous brain abscess," opened by Knapp, Schmiegelow, and Botey. There will be a museum of instruments and of anatomical and pathological specimens relating to diseases of the ear, nasal fossæ, and nasopharynx. At this congress also will be announced the award of the Lenval prize for progress in the relief of deafness.

**Cholera Epidemic in Turkey.**—An epidemic of cholera is reported to be raging at Kerbela, south of Bagdad. From December 9 to December 12, 176 deaths were recorded.

**Dr. W. W. Tarvin** of Covington, Ky., has been elected President of the Campbell and Kenton Counties Medical Association. He has been for nine years Coroner of Kenton County, and has also

served as United States Examining Surgeon, and as physician to the city jail.

**American Trained Nurses.**—Professor Renvers of Berlin has requested, through an American physician, a catalogue of the Training School for Nurses of the Cincinnati Hospital. The professor has heard so much of the excellence of the American trained nurse that he wishes to look into the system of training.

**Cincinnati Hospital Competition.**—The commissioners, Dr. C. R. Holmes and architects Drach and Hake, have stated that prizes will be offered for the best plans for a new City Hospital in Cincinnati. The prizes will be of sufficient value to induce the best architects in the country to compete. Fourteen acres of ground have been purchased and the commissioners favor the cottage or pavilion plan.

**Prof. Robert Koch** attained his sixtieth birthday on December 11. He was born in Clausthal in the Harz Mountains in 1843. His medical education was obtained in Göttingen, and he began practice in Langenhagen near Hanover, removing later to Rakwitz in Posen, and then to Wollstein, where he was sent as "Kreisphysicus." It was here that he began the studies in microscopic plant life, the marvellous results of which have earned for him the title of "Father of bacteriology." An interesting review of his life work, by Loeffler, is contained in the *Deutsche medicinische Wochenschrift* of December 10, and we join the writer in the wish that Koch may reach the years of the "Father of micrography." Anthony van Leeuwenhoek, who was prosecuting his investigations when well past his ninetieth birthday.

**Casualties on the Railroads of the Country.**—In the seventeenth annual report of the Interstate Commerce Commission, recently transmitted to Congress, it is stated that in the year ending June 30, 1903, the number of passengers killed in train accidents was 164, and of injured, 4,424; of employees killed, 895; injured, 6,440. Casualties from other causes, added to these, make totals of 321 passengers and 3,233 employees killed and 6,973 passengers and 39,004 employees injured. These numbers are larger by a considerable percentage than the corresponding numbers of the previous year.

**Vaccination of Railway Employees.**—The management of the Pennsylvania Railroad Company has issued an order requiring all trainmen and other persons in its employ to be vaccinated, and the work is now almost completed on many of the divisions of the road.

**The Condition of the German Emperor.**—At the opening of the Reichstag on December 14, Baron v. Ballestrem, the President, stated that Emperor William had apparently fully regained his old-time vigor. His voice was again clear and full, and only when one listened carefully could a slight huskiness be detected.

**Electric-light Baths** will become a fad of the day if what the London correspondent of the Cincinnati *Enquirer* cables to that journal is true. He says that the fact that King Edward gets through so much work and yet retains unimpaired his elasticity and vigor has been a source of wonder for a long time, but that an explanation of the mystery is contained in the announcement that His Majesty has been taking electric-light baths. A complete apparatus with fifty-two electric lamps has been installed at Windsor Castle and also at Buckingham Palace.

**Dr. George Ingle McLeod** of Ardmore, a suburb of Philadelphia, has had to have both feet amputated, in consequence of crushing injuries inflicted by the wheels of a moving train beneath which he slipped in attempting to embark.

**The Typhoid-fever Epidemic at Butler.**—Dr. George A. Soper, who was engaged by the *Engineering News* to investigate the typhoid epidemic at Butler, Pa., and its causes, has reported to that publication that the epidemic has by no means attained its culmination, about 50 per cent. of the cases not having reached the critical stage. The epidemic he attributes to the suspension of the mechanical filtration of the city water supply. In three weeks there were 1,000 cases, and up to December 14 1,247 cases and 51 deaths had been reported.

**The Late Drs. Davison H. Smith, J. F. Chauveau, and David Franklin.**—At a meeting of the Medical Association of the Greater City of New York, held December 14, 1903, the following report was received and adopted:

"It is with profound regret that your committee record the sudden and untimely death of Dr. Davison Heernance Smith, a member of this association and the son of its esteemed president. The subject of this sketch was born in New York in June, 1875. After a suitable preparatory course of study he entered the academic department of Columbia University, receiving in due course the degree of B. A. From the medical department of the same university he was graduated in 1902, and soon afterward he was admitted to the house staff of the New York Post-Graduate Hospital. It was in this institution that his death occurred from surgical shock, the result of a painful operation, bravely met, that was undertaken for the relief of mastoiditis. Possessing a genial and generous disposition, he endeared himself to a large circle of friends, and, though only on the threshold of his professional career, he gave promise of early success in a manifest zeal, earnestness of purpose, and faithful regard for duty. On behalf of this association your committee extend to the bereaved family of the deceased assurances of the inexpressible depth of its sorrow and sympathy in their affliction, and furthermore recommend that appropriate notice of his death be entered in the minutes of the association and that a copy be transmitted to his family.

(Signed) J. Blake White,
P. Brynberg Porter,
Wm. Seaman Bainbridge."

At the same meeting a report of the committee on the death of Dr. Jean F. Chauveau was presented, which was in part as follows: "A few months ago he celebrated the fiftieth anniversary of his entrance to the profession, an occasion which prompted the affectionate congratulations of a large number of friends who had learned to value the kindness and gentleness, as well as the wisdom, with which he always met the requirements of friendship and professional loyalty.

(Signed) A. B. Judson,
A. B. Ball,
F. E. Sondern."

Also a report of the committee on the death of Dr. David Franklin, the concluding portion of which was as follows: "Of him it may be truly said, medicine was his religion and his politics, his happiness and his misery. He was of unimpeachable honor and integrity. He had the gentleness of a woman and the nerve of a man of steel. He was keenly observant and of wonderful patience and endurance. He was beloved by his friends and adored by his patients." It was voted that the association "express by a record on its minutes its deep sense of loss in the death of Dr. Franklin, and that a copy of these resolutions be sent to his family, together with

an expression of the association's profound sympathy.

SAMUEL M. BRICKNER,
EDWARD FRIDENBERG."

**St. Luke's Hospital, Chicago.**—This institution will profit by the charity ball given on December 15. The hospital was founded in 1864 by Rev. Clinton Locke, who, until about ten years ago, was rector of Grace Episcopal Church. It has been supported since by his parishioners and friends. Dr. Locke first rented a three-story frame house in State street, between Twelfth and Thirteenth streets, which soon proved inadequate, when he obtained from E. H. Haddock a large three and one-half story frame house in Indiana avenue, between Fourteenth and Fifteenth streets. This structure still stands fifty feet south of the present brick house, that contains 150 beds. The ball netted $20,000, which will go toward building an annex to the hospital.

**Civil-service Examinations.**—The State Civil Service Commission announces general examinations to be held January 9, 1904, including the following positions: Apothecary in State hospitals and institutions; laboratory assistant in State Antitoxin Laboratory, Albany; physician, fourth and fifth grades of both regular and homœopathic schools. Applications for these examinations must be made on or before January 4. Full particulars of the examinations and blank applications may be obtained by addressing the Chief Examiner of the Commission at Albany.

**Southern Medical College Association.**—This Association met at Atlanta, Ga., December 14, the day preceding the meeting of the Southern Surgical and Gynecological Association. The following colleges were represented: Medical College of Virginia, Dr. C. Tompkins, President of the Association; Medical Department of University of Nashville, J. D. Jacobs, Vice-President; Medical Department of Vanderbilt University, G. C. Savage, Secretary and Treasurer of the Association; Medical Department of University of the South, J. S. Cain, Chairman of the Executive Committee; Birmingham Medical College, J. C. LeGrande, a member of the Executive Committee; Medical Department, Fort Worth University, Bacon Saunders; Medical Department, University of Tennesses, Dr. R. O. Tucker; Medical Department, Baylor University, J. M. Rosser; Tennessee Medical College, Knoxville, Chas. P. McNabb; Medical Department, University of Mississippi, J. B. Bullitt. The president in his address recommended that still further advancement be made in the way of preliminary requirements, and there was an amendment offered to the constitution with that in view, this amendment requiring a grammar school education plus two years in the high school. An amendment to the constitution was adopted requiring that forty-one months shall intervene between matriculation for the first course and the date of graduation, and requiring eleven months, shall intervene between the matriculation for any one course, and the matriculation for the next succeeding course. The Memphis Hospital College applied for readmission into the association, but the application was laid over for one year, according to the constitution. The meeting was a very satisfactory one, showing that actual advancement was taking place, and the consensus of opinion was that ultimately there will be nothing in the way of amalgamating the Southern College Association with the Association of American Medical Colleges. The officers for the ensuing year are: *President*, Dr. C. Tompkins; *Vice-President*, Dr. Bacon Saunders; *Secretary-Treasurer*, Dr. G. C. Savage; *Chairman of the Executive Committee*, Dr. J. S. Cain; *Members of the Executive Committee*, Drs. L. C. LaGrande and James Rosser. The next meeting of the association will be held on the day procceding the meeting of the Southern Surgical and Gynecological Association, at whatever place may be determined by the latter.

**Contagious Diseases in Illinois.**—Canton, Ill., reports one hundred cases of typhoid fever, with ten deaths. Scarlet fever and diphtheria are epidemic at Geneva, and the public schools have been closed. Since October 25 there have been seventeen cases of diphtheria in Pekin.

**Reappointment of Dr. Reynolds.**—Mayor Harrison of Chicago reappointed Dr. Arthur R. Reynolds, Commissioner of Health, on December 14, and the City Council has confirmed the appointment.

**Pathological Society of Philadelphia.**—At a stated meeting, held December 17, Dr. J. Norman Henry exhibited a specimen of rupture of the heart. The wall of the left ventricle was greatly thinned near the apex and dilated into an aneurysmal formation, which was partially accupied by clotted blood. Rupture had taken place into the pericardium. Dr. Henry exhibited also an infected echinococcus cyst of the liver. During life empyema was suspected, but on operation no pus cavity could be found. Dr. Joseph Sailer and Dr. Richards presented a preliminary communication on "Acid-fast Bacilli Other than Tubercle-bacilli in the Sputum," reporting the case of a man presenting symptoms suggestive of a gangrene of the lung, and in whose sputum were found cocci arranged in pairs and in chains that, on staining with aniline colors, were not decolorized by mineral acids. Dr. Robert N. Willson, Jr., reported the case of a medical student presenting physical signs of pulmonary tuberculosis, with repeated hæmoptysis, in whose sputum, only after repeated examination, were found slender bacilli that when stained with fuchsin did not yield up their color to mineral acids. Dr. Wm. G. Spiller read a paper entitled "Intense General Muscular Atrophy Due to Inflammation of the Brain." The patient had been a feeble-minded girl, sixteen years old, presenting extreme general muscular atrophy, and whose father, also feeble-minded, had been an alcoholic and possibly also syphilitic. After death a condition of general encephalomyelitis was found in the child. Dr. Leo Loeb read a paper entitled "Some Recent Contributions to the Subject of the Causation of Cancer." Dr. Henry W. Cattell made a demonstration of cryoscopy and pointed out the purposes for which it may be employed. Dr. T. H. Weisenburg presented a communication entitled "Changes in the Central Motor System in Uræmia." He related two cases of hemipegia of uræmic origin, in one of which death occurred fourteen days, and in the other four days, after the onset of the symptoms. In neither was any lesion demonstrable macroscopically, but on histological examination there were found atrophy and dense yellowish pigmentation of cells in the cerebral cortex, and the spinal cord associated in the first case with primary degeneration of motor tracts in medulla, spinal cord, and up to the level of the internal capsule. Dr. Farr exhibited a liver, the seat of an abscess, obtained from the body of a patient who presented also an empyema of the right pleura, the urine during life containing albumin, tube-casts and sugar, and death having been suspected to be due to diabetic coma. Dr. Joseph Sailer exhibited a heart with a distinct membranous formation attached to the anterior leaflet of the mitral valve, without appreciable murmur during life; also lungs

presenting extensive metastatic deposits secondary to sarcoma of a previously removed mammary gland, and also anthracotic lungs from a miner.

**College of Physicians of Philadelphia, Section on General Medicine.**—At a stated meeting, held December 14, Dr. Norman Henry reported two cases of urcinariasis (old-world parasite). Dr. Joseph Sailer exhibited a colored man, with marked dyspnœa and great difficulty in inspiration, almost total immobility of the chest in respiration, which was principally abdominal in type. There had been no notable loss in weight, but the heart had undergone some enlargement, and examination with a bougie pointed to obstruction of the œsophagus. The diagnosis was obscure. It was thought aneurysm could be excluded, and the most likely condition seemed to be a mediastinal neoplasm compressing œsophagus and bronchi and partly displacing the heart. Dr. Sailer also read a paper on "Asthma of Gastric Origin," reporting the case of a civil engineer, who suffered from dyspnœa and noisy breathing, with râles and other evidences of asthma, in the sequence of or association with digestive derangement and indiscretions in diet. Attention to these apparent etiologic factors, and especially to the use of the stomach tube with lavage, was followed by a repression of the symptoms. The latter symptoms, it was thought, in cases of this and allied kind, might at times be reflex and at other times toxic. Dr. D. L. Edsall read a paper on the "The Clinical Behavior of the Lymph-glands in Typhoid Fever," in which he related a small series of cases of typhoid fever presenting such enlargement of lymphatic glands in various parts of the body. Dr. James Tyson read a paper entitled "Appendicitis: the Case Which Completed My Conversion." The case was that of a young man in whom the diagnosis of appendicitis was made and operation was deferred, in part owing to the apparent mildness of the attack and in part to the fact that the patient was at some distance from the hospital, where it was preferred the operation should be performed. After the abdomen was opened an abscess was found in the right iliac fossa, and it ruptured on the slightest touch. The conclusion was, therefore, reached that, inasmuch as it is impossible to determine what will be the outcome in any given case not treated surgically, the only safe course to pursue is to operate as soon, after the diagnosis is made, as operation can be properly undertaken. Drs. J. Dutton Steele and A. P. Francine presented a communication entitled "Two Years' Experience in Gastroptosis." The communication was supplementary to previous papers on similar subjects, and dealt with cases that had remained under observations for almost the entire period named. The cases were of two kinds, namely those in which the displacement of the stomach was the principal condition, and those in which it was merely incidental. The resulting symptoms varied widely in character and intensity, but they were in general helped by the wearing of a mechanical support, even when this failed to correct the displacement. In cases that resist other measures of treatment appropriate surgical intervention would seem justifiable.

**Obituary Note.**—Dr. FRANCIS W. HIGGINS of Cortland, N. Y., died very suddenly on December 18, at the age of forty-six years. He was a graduate of the New York University Medical School in 1881. At the time of his death, he was president of the Third District Branch of the New York State Medical Association and one of the vice-presidents of the State Medical Association.

# Correspondence.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

GENERAL MEDICAL COUNCIL—BART'S ARSENIC COMMISSION—SLEEPING SICKNESS—PERFORATING GASTRIC ULCER—HEART FAILURE—BACTERIOLOGY OF MILK—SIGNS OF LIFE—SHAMBLES OF SCIENCE—SIR J. B. MAPLE.

LONDON, December 4, 1903.

THE General Medical Council continued its sittings over Monday, November 30. The disciplinary and routine work was performed. That which more interests the profession is the disagreement between the Council and the two royal colleges which has "dragged its slow length along" for years, and even now is unsettled. Sir V. Horsley brought in his motion to represent the case to His Majesty's Privy Council, but he was not able to carry it. There was, as usual, a long and weary debate with numerous side issues and a determination of the college representatives to prevent so serious a move. These gentlemen stated that the colleges were still considering the matter, but they could not fix a date for a definite result. They suggested that perhaps next session they might have one. Eventually the Council resolved, by a majority of one, to wait until the May session. So far the colleges have the best of it. The indications are that they are preparing to give way, and all this obstruction and delay is only to "save face."

The future of St. Bartholomew's Hospital has continued to occupy public attention all the week.—Sir H. Burdett and others discussing it in the *Times* and most of the newspapers offering their speculations on the subject. The opposition to the Mansion House scheme seems to be growing. Yesterday Sir H. T. Burdett read a paper at the Hospital's Association in which he urged several objections to the scheme. He said the architect who planned the hospital deserves our admiration for his unique arrangement of the four ward blocks which occupy the sides of a hollow square, but each of the four separated and self-contained, so that there is a free circulation of air round each block as well as through the hollow square. This is remarkable, as in 1730 it was usual to join all such buildings together. The name of the architect has not been preserved. The sum of £350,000, which the Mansion scheme proposes to spend, the lecturer declared, would be wasted, "and lead to the ultimate destruction" of old Bart's. He would go in for a scheme requiring about double that amount.

The final report of the Royal Commission on Arsenical Poisoning was obtainable yesterday. It gives the total number of persons affected in the poisonous beer in 1900 as certainly 6,000, probably much greater. The deaths, 70. The commissioners adhere to the view that no quantity of arsenic, however small, should be admissible, into articles of food. They think serious defects exist in the machinery for safeguarding the public against the introduction of poisonous, deleterious, or valueless substances into food. The work of local authorities in this matter they would have coördinated by the local Government Board, which should have the aid of an expert, who should be connected with the Government Laboratory. They think official standards must be applied, and, pending their establishment, it will be proper to inflict fines whenever the $\frac{1}{10}$ grain of arsenic is detected in a gallon of liquid, or a pound of solid, sold for consumption.

Dr. Nabarro's stay in Uganda has been extended by the Colonial Office to enable him to extend his studies. In a letter to a friend in London he says there is no reason why whites might not be attacked with sleeping sickness. The parasite, it seems, may live in the blood for a long time before it reaches the brain, when sleeping sickness ensues. It is not every tsetse fly which harbors a parasite, and while people are clothed so that they are less likely to be bitten, and they do not allow the fly to settle on them and bite them as natives do. Moreover, whites do not go much into the fly areas.

At the last meeting of the Medico-Chirurgical Society the paper was by Mr. Crisp English, and was based on fifty consecutive laparotomies performed at St. George's Hospital for perforated gastric or duodenal ulcer (acute cases only)—forty-two gastric with twenty-two recoveries; eight duodenal with two recoveries. Premonitory symptoms were noted in 29 per cent., mostly chronic and severe cases. Vomiting in 75 per cent. Liver dulness normal in eleven, absent in twelve, diminished in twenty cases. The most common seat of perforation was the lesser curvature, and next to that near the pylorus. Complications occurred in thirteen of the successful and eight of the fatal cases—among them parotitis, pleurisy, thrombosis, hæmatemesis.

In seven cases presenting the signs of perforation laparotomy showed it has not taken place; in three of these nothing abnormal was found, in one only blood-

stained œdema of the gastric omentum, in another appendicitis, in one other evidence of a small ruptured ovarian cyst. In thirteen of twenty-one cases which came to necropsy other ulcers were found, mostly just opposite the perforation. The after-condition of seventeen of the successful cases had been ascertained—of these twelve had no return of symptoms, four had had slight dyspepsia and one complained of symptoms thought to be due to peritoneal adhesions.

Mr. Turner said seven of the cases referred to were under his care with five recoveries. The two fatal ones seemed hopeless on admission. In two of the recoveries there was thrombosis of the leg veins, a not uncommon thing in appendicitis. He used drainage in all and thought it beneficial.

Mr. Haward thought drainage advisable when a considerable period had passed before operation. If there was much escape from the stomach or a long time had elapsed, irrigation should be employed, and this was always on the safe side. He thought the pleurisy was produced by septic matter passing through the lymphatics.

Dr. John Broadbent mentioned two cases of traumatic rupture of the duodenum—one in a child, who fell across a chair, the other in a man on whom a ladder fell. Both died after a "quiescent period," which he thought more common after duodenal than gastric perforations.

Dr. French had seen gastric ulcer in locomotor ataxy and referred to the differential diagnosis from the crisis of tabes and from thrombosis of the vena cava, He had known a man suffer severe pain for two years after the operation.

Mr. Keetley since 1899 had operated on nine cases with six recoveries. These six had been operated on within thirty hours, the fatal ones after three or four days.

Mr. Newton Pitt preferred chopping out the abdominal cavity to irrigation, unless the extravasation was considerable in amount.

Dr. V. Pearson said diminution of liver dulness was frequent enough without perforation. He had found it in about one-third of all cases admitted for hæmatemesis. Perhaps it was dependent on a dilated colon, though that was hardly a satisfactory explanation.

Mr. Paterson was opposed to both irrigation and mopping. Both produced shock. He used simple drainage with gauze. He controverted the reasons given by Mr. English against gastroenterostomy.

Mr. Clinton Dent held that the less irrigation or interference the better. Gastroenterostomy was unnecessary and did not fulfil the objects it was proposed for. Even if it was not done he thought patients should be fed early after the ulcer had been closed.

A discussion on the Treatment of Heart Failure was held on the 23d ult. at the Medical Society. It was opened by Sir Douglas Powell, who limited his remarks to acute cases and instanced (*a*) sudden death in aortic regurgitant disease in which death arose from syncopal failure of the cerebral circulation from failure of the heart in the diastolic period. (*b*) An anginoid variety of this when death was threatened in an attack of vasomotor angina. Here the peripheral vessels were contracted, not dilated, and the blood retained in the arterial capillaries and nerve centers, so that the failure might be delayed long enough to admit remedies (nitrites, strychnine, morphine). (*c*) Another variety occurs in mitral stenosis, when the patient recovering from urgent symptoms is fed up to the point of plethora. Here a prompt bleeding might prevent disaster, but its necessity would have been avoided by spare diet and laxatives. In pneumonia, similiar though more complex conditions might occur—weakened heart, impaired lung function, capillary stasis.

The approaching overdistention of the right heart could be watched in its increased dimensions and loud second sound, with limited output recognised in the small quick pulse which failed in the inspiratory period. Venous stagnation was also shown in liver fulness and albuminous urine. It was most important not to overfeed such patients. In pneumonia, strychnine, and oxygen, Sir D. Powell's experience convinced him that strychnine was a direct cardiac stimulant, though some pharmacologists held that it only acted by contracting the arterioles. Oxygen was a cardiac stimulant carried in the blood direct to the heart. Digitalis was chiefly of use when the rhythm was disordered. Caffeine may supplement strychnine, or sometimes replace it. In Addison's disease, hemorrhage and collapse after abdominal injury or operations, the blood-pressure was so low that there was a tendency to transfer blood from the arteries to the veins. To raise the tension and prevent this transfer ergot, suprarenal extract and saline infections were useful, the heart being still supported by strychnine. Digitalis was then contraindicated. Opium was of use in cardiac shock or pain, in painful apart from syncopal, angina, in irregular, tumultuous or inhibited action of the heart, such as in the initial shock of pleurisy or pericarditis. In the cardiac agitation, restless dyspnœa and air hunger, which often preceded the appearance of dropsy, the only remedy seemed subcutaneous injection of morphine.

In the discussion, if such it may be called, which followed, the speakers for the most part agreed with Sir Douglas, and added scarcely anything to his statements.

Sir Broadbent alluded to degeneration of the cardiac muscle, but Sir Douglas had expressly confined his remarks to acute failure. Sir William also spoke of the use of venesection in pneumonia and sudden death in mitral stenosis brought on by a distended stomach. Sir L. Brunton on this point advised fluids to be taken apart from the solids of the diet. He said his experiments proved that strychnine caused recovery of the frog's heart after its arrest, showing it to be a direct cardiac stimulant.

Dr. M. Bruce supported the use of venesection as above, and remarked that the majority of deaths occuring in the night were caused by an undigested meal. In heart failure, from chronic valvular disease, or in kidney disease he gave digitalis freely—℥ x to xv every four hours, regulating it by the amount of urine passed.

Mr. Barker and Mr. Mayo Robson spoke of shock in abdominal operations and its prevention by warmth, saline injections, adrenalin, strychnine, etc., also by refraining from too much handling of the viscera.

The "Bacteriology of Milk" is the title of a twenty-five shilling volume just out, in royal 8vo, by Mr Swithinbank and Dr. Geo. Newman, both experienced bacteriologists. It is illustrated with chromo-lithos, photographs, and engravings..

Another important work out this week is Dr. Augustus Waller's "Signs of Life—a Series of Lectures on Physiology," at the University of London. Both these works are published by Mr. John Murray.

The publisher of the "Shambles of Science," which obtained notoriety through the vivisection libel case, has withdrawn it from circulation and offered an apology to Dr. Bayliss, which he has accepted.

Sir J. Blundell Maple, who died last week, was well known in connection with various subjects. His chief title to fame is as a generous philanthropist, for he undertook the entire cost of rebuilding University College Hospital, which will amount to about £150,000.

## Progress of Medical Science.

*The Boston Medical and Surgical Journal, Dec. 10, 1903.*

**A Case of Gumma of the Fallopian Tube.**—George S. Whiteside reports this case: The patient was a woman aged thirty-seven years. She had had eleven pregnancies and two miscarriages. She had a clear history of syphilis dating back five years. Both miscarriages had taken place within that time. About a year after she was first seen by the writer she was delivered of a healthy child. In this pregnancy she had been put on iodide of potassium three times a day. More than a year after the delivery of this child, she presented herself again for treatment. She had been receiving no antisyphilitic treatment during the past year. She had been suffering pain for two months past in the right iliac fossa. The pain was worse at night. There was some pain in the back, headache, and malaise. The catamenia were too frequent and too profuse. Examination under ether revealed on the right side a tumor the size of a large lemon, apparently the right Fallopian tube. She was ordered hot douches, rest, and the other usual remedies without success. She would allow no surgical treatment. She was put on a rigorous antisyphilitic mercurial and iodide treatment. The tumor constantly grew smaller. In ten weeks it had entirely disappeared. During this time her symptoms had gradually improved, and at the end of thirteen weeks she considered herself well. After two years there has been no recurrence. The writer thinks that it is probable that this tumor was a gumma of the Fallopian tube.

**The Indol of the Fæces as a Measure of Putrefactive Processes in the Intestines.**—A. E. Austin describes the method employed for determination of the indol, phenol, etc., in the stools. The day's fæces were first weighed and a portion weighed out for the determination of the water, which portion was afterward destroyed for determination of the lime. Another portion was weighed out for the nitrogen estimation, and the remainder mixed with water until it formed a thin mixture, and then one-third was distilled off. This distillate was then made alkaline with sodium carbonate to hold the fatty acids, and a second distillate was made. This distillate was then made strongly alkaline to hold the phenol in check and distilled with steam as long as any indol was found to

go over. In order to remove those portions which clung to the distilling tube, ether was added to the last solution, and its vapor dissolved out all the indol and carried it to the flask lying before the condenser. This watery solution of indol (and skatol) was repeatedly shaken with ether, the ether distilled until some began to fall out of solution, and then allowed to evaporate spontaneously in a weighed beaker, dried in a vacuum over sulphuric acid and weighed. The writer then cites several cases which were regarded clinically as examples of so-called chronic catarrhal colitis, or ileocolitis, of which mucous colitis or ileocolitis seems, from descriptions of others, to be a similar term. In these cases he estimated the chemical composition of the fæces. The amount of indol found was vastly greater than that found by Baumstark, who regarded 17 mgms. as an average normal quantity in the day's stool. The amounts of indol found in some of the author's cases were, respectively, .022 gms., .260 gms., .160 gms., and .244 gms. There can be no question as to the purity of these products. The writer suggests that his much larger amounts may be due to the fact that the skatol was reckoned with the indol, in his cases.

*Journal of the American Medical Association, Dec.* 19, 1903.

**The Capacity of a Human Muscle for Work.**—J. G. Holmes reviews previous discussions of this question and then gives a full, illustrated account of his own experiments. His conclusions are as follows: (1) A muscle working under normal physiological conditions is neither "loaded" nor "after loaded" (the former refers to the condition of experiments with the weight ergograph and the latter with the spring ergograph). (2) A muscle will not contract isotonically nor isometrically under normal physiologic conditions. (3) When a Mosso or a spring ergograph is used, a large part of the energy expended by a muscle during a period of work is lost. This loss occurs in easing back the weight or the spring to its position of rest or to the zero point. (4) A recognition of the conditions under which a muscle works and the end to be attained is necessary when an interpretation of ergographic results is to be made. (5) A normal muscular contraction ("normotonic") consists in contraction, relaxation without load, rest. (6) A new form of weight ergograph has been devised which allows the human muscle to work at a greater advantage than that given by any previous form of ergograph, because it permits "normotonic" contractions. (7) A human muscle is capable of doing a far greater amount of work by the use of the new ergograph than has been previously shown in ergographic work. (8) A muscle can work over periods of long duration without fatigue when the conditions are favorable. (9) These experiments confirm the conclusion stated by Maggiora that there is a definite weight with which one can perform the greatest possible work. (10) The physiologic limit of a muscle for continuous work is modified by the rate, load, and interval, or by rest and work.

*Medical News, December* 10, 1903.

**Peripheral Neuritis. A Clinico-therapeutic Résumé.**—William Broaddus Pritchard emphasizes certain facts in his therapeutic summary: Functional rest is most important in all cases of neuritis, often to the extent of mechanical enforcement; forced nutrition is also valuable, especially with fats, both constitutionally and locally, cream, butter, and lanolin by inunction being always indicated. The writer has great confidence in electricity and massage, neither of which, however, should be used empirically, both of which require, in individual cases, the utmost nicety of personal adjustment. He calls attention to the importance of maintaining an equable surface temperature in all forms of sensory neuritis, which is best attained by the use of lamb's wool fleece. In each case the neurotic habit tendencies and predispositions, which vary widely, should be carefully observed and met with corrective nerve discipline. It is likely that the method will vary with each case. All cases of neuritis, except perhaps the traumatic and mechanical, are associated with, and often dependent upon, states of altered metabolism and perverted nutrition, to which recognition is logically correlated the necessity of tonic alterative and nutritional measures.

**The Surgical Treatment of Dysmenorrhœa.**—Wm. E. Parke declares that the symptoms of true obstructive dysmenorrhœa is pain, which has the cramp-like character of labor pains. It may follow an operation, or there may be a new growth. The operative treatment of this condition consists in the removal of the cause. In case of a new growth it should be removed if feasible. Dilatation sometimes benefits the cases in which the uteri are small and anti-flexed. The surgical treatment of membranous dysmenorrhœa consists in a wide dilatation, curettage, and application of pure carbolic acid to the endometrium. This treatment gives relief from the severe pain for a time and occasionally cures the disease. The simple operation of dilatation and curettage finds its greatest field for usefulness in the cases of spasmodic dysmenorrhœa. Congestive dysmenorrhœa, pure and simple, does not require surgical treatment for its cure. But when it is secondary to certain pathological changes in the uterus or its appendages some operative measure offers the only substantial relief. For example, a retroflexed uterus should be not only dilated and curetted, but the organ should be restored to the normal position by an appropriate operation. A uterus whose appendages are known to be diseased should never be dilated and curetted unless at the same time an appropriate operation is done upon the appendages.

**The Dangers of Inflating the Stomach with Carbonic Acid Gas; Its Diagnostic Value. Report of Three Cases with Autopsies.**—Moses Behrend reports several interesting cases in which death followed inflation of the stomach with $CO_2$ gas. Autopsies were performed in each case. The first case was a patient sixty-eight years old. She suffered from anorexia, eructations of gas, variable bowels, headache, vertigo, palpitation, dyspnœa, pain across the epigastric region, and vomiting immediately after eating. A seidlitz powder was administered, which distressed the patient greatly. About half an hour afterward she vomited a quart of blood and at irregular intervals, during the course of twelve hours, large quantities of blood were ejected. Twenty hours after taking the powder she died. Autopsy revealed the rupture of a blood vessel at the base of an ulcer from which fatal hemorrhage had ensued. The second patient was a man aged seventy-three years. His chief complaint was vomiting after eating. The $CO_2$ test was tried in this case, and a large quantity of froth and a little blood were vomited or rather regurgitated immediately. After the $CO_2$ was taken, the stomach was not distended. The patient was extremely prostrated immediately after its use and never rallied. He died on the following day. At autopsy there was discovered carcinoma of the œsophagus and stomach. In the third case, that of a man aged fifty-two years, the chief complaint was pain just below and to the left of the sternocostal angle. Distress followed the administration of the $CO_2$ test and he was in a more or less semi-conscious condition till the time of his death. Autopsy showed that the œsophagus was dilated throughout its entire length. From these observations it is evident that the use of $CO_2$ gas in inflating the stomach is a serious matter. The lives of all of the above patients were undoubtedly shortened by this treatment.

*New York Medical Journal, December* 19, 1903.

**Things Every Tuberculous Patient Should Know.**—The paper of M. L. Stevens is made up of a set of rules to be placed in the hands of consumptives, and cover all necessary points. Under the head of "Open air," he notes that night air is not harmful, but less beneficial than day air because lacking sunlight. Under "cough and expectoration" he says that the belief that sputum expectorated on to the ground in sunny places is harmless because of the disinfecting power of the sun's rays is both erroneous and pernicious. You have no assurance that infective material from it may not be carried away almost immediately by flies, or by the shoes and skirts of unwitting persons.

**The Natural Habitat of the Tubercle Bacillus.**—J. W. Kime believes that all tuberculosis is originally of bovine origin, and that in the cow is found the natural habitat of the disease. It is now found, it is true, in many other animals, but it is also certain that when the germs are taken directly from the cow to any of these other animals, they sicken and die with much greater certainty and celerity than when drawn from any other source. Hence the author concludes that the cow furnishes the type of soil and tissue best adapted to the production of virile tubercle bacilli, and that the more immediate the transference of tuberculosis from the cow to man, the more deadly it becomes and the more readily it may be transferred back to the cow again; while cultures many generations removed from the cow lose much in virulency, are comparatively innocent in their effects, and are with great difficulty carried back to the source from which they took their origin. Hence, it is highly improbable that the rule is reciprocal in its action, and that if not transferable to the cow from man it may not be transmitted from cow to man.

*American Medicine, December* 19, 1903.

**The Diagnosis of Trichiniasis.**—William Fitch Cheney states that the data upon which the diagnosis of trichiniasis depends are these: Muscular pain, usually severe and wide-spread, due to a general myositis; continued or remittent fever, resembling that of typhoid; a persistant leucocytosis, averaging from 10,000 to 20,000; an increase in the eosinophiles, varying from 10 per cent. to 50

per cent.; the presence of trickinæ in the muscle tissue; and to these should be added œdema about the face and ankles, on which as a diagnostic feature much stress is laid by Osler and others; least valuable of all a history of having eaten pork. As to the value of eosinophilia in the diagnosis of trichiniasis two questions present themselves: Is it constantly present, and does it occur only in this disease? In the light of all the knowledge so far obtained, eosinophilia is not constantly present in this disease, but is so in the great majority of cases. As to the second question, eosinophilia does occur in a number of other conditions besides trichiniasis, but these all vary so widely from the clinical picture of trichiniasis that practically no difficulty is offered in the differential diagnosis. The finding of trichinæ in the muscle tissue is a positive proof of the presence of trichiniasis.

**Indications for Operations on the Gall-bladder and Bile ducts.**—Randolph Winslow says that the conditions which demand operations on the gall-bladder and bile-ducts are: Cholelithiasis or gallstones, cholecystitis and cholangitis, adhesions to surrounding parts, rupture of the gall-bladder, and malignant neoplasms, either affecting the bile passages, or pressing on them from without. There are some other pathologic conditions met occasionally. Of these conditions that of gallstones is by far the most common. In all forms of gall-bladder and bile-duct disease the cardinal symptoms are pain, tenderness in the upper part of the abdomen, muscular regidity, jaundice, fever and often a tumor. Many painful conditions of the abdomen are due to undetected gallstones. In most cases of disease limited to the gall-bladder there will be no jaundice, but when there is cholecystitis with accompanying cholangitis there may be jaundice. The signs of gall-bladder disease are not so much due to the actual presence of the stone, as to the inflammation which so often accompanies them, and which is due to infection, usually entering at the papilla and traveling up the ducts to the viscus. Cases in which the gall-bladder is inflamed and distended, but quite free from concretions, demand operative treatment, such as incision and drainage, and perhaps removal of the diseased gall-bladder equally as much as those in which calculi are present. The complications of cholecystitis are also both important and serious. In the case of a gall-bladder so distended and unduly mobile that a kink occurs at its neck, with an exaggeration of the colic and other symptoms, operation offers the remedy. When cholecystitis is complicated by gangrene, due to the intensity of the infection and the overdistention of the gall-bladder, either operation will speedily relieve the condition, or death will terminate it, from sepsis or rupture with peritonitis. In the case of rupture of a cyst in the contents of which pathogenic organisms exist, a prompt laparotomy with removal of the exuded bile, pus, or calculi and a careful cleansing of the peritoneum offer the only hope of a successful issue. The results of operative treatment are not very encouraging in cases of malignant disease of the liver, gall-bladder and bile ducts. In the conditions mentioned in this paper the difficulty and danger of operation increase in proportion to the length of time the affection has been in existence. When good results are not apparent after a fair trial of internal treatment, operative measures should be resorted to without further delay.

*The Lancet, December* 5, 1903.

**Fever, Foliaceous Desquamation, Morbilliform Eruption and Albuminuria from Copaiba.**—The patient of J. C. MacWalter was a man of twenty-two years who had been taking twenty minims of copaiba during an acute gonorrhœa. Although the rash which he exhibited was not unlike a copious copaiba eruption, the temperature of 102°, which had only abated to 101° by the next day after he had ceased to take the medicine and remained in bed, the general feeling of malaise, the throat conditions, and the fact that after three days a desquamation so considerable set in that foliaceous flakes of epithelium were shed off and regular casts of his fingers could be removed, led the author to fear he had been mistaken in attributing the eruption to the drug. This seemed to be the more likely as albumin was present in the urine in the earlier stage, though it quickly passed off. The patient made a good recovery, however, and was all right in four or five days though the desquamation continued a while longer.

**On Albuminuria as an Accompaniment of Diabetes.**—F. W. Pavy concludes his article in this issue, narrating several additional cases and commenting thereon. The general consideration of the clinical histories shows that the albuminuria which occurs in connection with diabetes may exist for a long time without leading to the production of any symptomatic indication of its presence. The condition, therefore, is not to be looked upon as affording ground for apprehension in the same manner as when occurring under other circumstances. It is evident that albumin and casts have a very different signification according to the condition with which they are associated. Experience shows that even apart from diabetes they are with striking frequency come across in persons of advanced age presenting nothing to suggest the existence of renal mischief. They may, it is true, be the inceptive of something that may assume later on a more developed form, but, on the other hand, time may pass away and signs fail to appear of any further development.

**Continuous Local Infection.**—Several modes of this form of infection are mentioned by R. J. Godlee and pertinent case histories are given. The list includes appendicitis and pyorrhœa alveolaris. From the latter may come septic fever, rashes, and profound septicæmia, purpuric hemorrhages and bleedings from the gums, toxic neuritis, septic gastritis, stomatitis, pharyngitis, and tonsillitis, ulcerative endocarditis, pernicious anæmia, chronic dyspepsia, and bronchiectasis. Still another manifestation of continuous infection is the development of lardaceous disease in the subjects of chronic suppuration. This latter may originate in the mouth from the cause above named, viz., pyorrhœa. Noteworthy features about lardaceous disease are: (1) that while some individuals may remain free from it for many years who suffer from a chronic issue of pus, others develop the disease and fall victims to it in a comparatively short space of time; (2) that though it is very often associated with clubbing of the extremities the two conditions may occur singly or one may precede the other by a long interval; and (3) that if the cause of the disease is removed an almost complete recovery may take place even when the viscera have been profoundly affected. In the category of local infections we may also include pulmonary osteoarthropathy, the septic osteoarthritis of young women often accompanying leucorrhœa, tuberculous glands, and acute infective osteomyelitis. In all the foregoing the cause of the patient's ill-being may easily be overlooked and treatment be without avail because the purulent focus is not found.

*British Medical Journal, December* 5, 1903.

**A Lecture on Means for the Prolongation of Life.**—Hermann Weber, in considering the principal factor of inherited longevity ascribes to the circulatory system the greatest share of credit. However, this cannot be separated from the respiratory system and from the vasomotor part of the nervous system. Death from old age is caused by a kind of atrophy of the tissues and organs connected with the changes in the blood-vessels, and the atrophy of the hæmatogenic glands. The most efficacious means to prevent early decay and to keep the circulatory system in a healthy condition are found in the different forms of exercise. Walking is the most natural form of exercise. More blood is passed into the blood-vessels, which are obliged to contract more frequently and carry it with greater energy to the different organs and tissues so that all the body is nourished. The action of the heart and the breathing are accelerated. The number and depth of inspirations are increased, more oxygen is taken up, and more carbonic acid is given out. The amount of walking necessary to maintain health varies widely in different persons and under different circumstances, from half an hour to two or three hours a day. So-called bad weather should offer no interruption. It is of great use for those who are still in fair vigor to take regularly, once a week, a day of more prolonged exercise of from four to six hours. Those in town, if possible, should spend this day in the country. More beneficial than the once-a-week extra exercise is the plan of taking once or twice a year a walking or climbing tour of three to four weeks or longer in the mountainous districts. This regular exercise should be supplemented in many cases by respiratory exercises. The habit should be formed of taking several times a day besides, deep inspirations and expirations, especially while walking. The writer then mentions tension exercise, which consist in the static contraction of all the muscles of the body while standing, from one to two minutes several times a day. The air in the house should be kept as pure as that out of doors. Great moderation should be observed in the amount of food, especially of the most nourishing articles (particularly flesh food). No food should be swallowed until it has been perfectly masticated and mixed with saliva. Alcohol is not necessary to healthy persons, and most people would be better without it. Cocoa and chocolate are much more articles of food than tea and coffee, and have much sustaining power in fatiguing climbs and other exertions. Every organ of the body as far as possible should be kept in constant working order. Excessive smoking is injurious to the majority of people. The amount and quality of food are of great importance to persons with sluggish bowels. Massage of the abdominal organs is often satisfactory. Voluntary and systematic contraction of the muscles of the abdominal wall is very useful in constipation. A glass of hot or cold water, or of some aërated water an hour or two before breakfast is often beneficial. The writer gives various

other directions. Going to bed early and rising early, and restricting the hours of sleep to six or seven hours; daily baths or ablutions, according to individual conditions, cold or warm, or warm followed by cold; regular work and mental occupation; cultivation of placidity, cheerfulness and hopefulness of mind; employment of the great power of the mind in controlling passions and nervous fear; strengthening the will in carrying out whatever is useful and in checking the craving for stimulants, anodynes, and other injurious agencies.

**On a Dysentery Antitoxin.**—Charles Todd concludes that: (1) By growing the dysentery bacillus in a somewhat highly alkaline broth a soluble toxin is obtained. (2) Certain animals, notably the horse and rabbit, are highly susceptible to this toxin. (3) The toxin is fairly stable, and though destroyed by an exposure to a temperature of 80° C. for an hour, is not destroyed by exposure to a temperature of 70° C. for the same period. (4) When injected into suitable animals—for example, the horse—the toxin gives rise to a powerful antitoxin. (5) The combination of the toxin and antitoxin in vitro does not take place immediately, but requires a certain time, and the rate of combination varies with the temperature.

**Hyperpyrexia in Measles.**—E. Barnes reports a recent epidemic of measles in which he treated about fifty cases. Four of these died, all from hyperpyrexia. They all had lung complications. The temperature in each of three cases reached about 106° F. In the fourth case it ran up to 111° F. This temperature was confirmed by three thermometers. The treatment adopted was the application of cold to the body, tepid baths with ice added, and ice to the head. No effect was seen on the temperature.

*Deutsche medicinische Wochenschrift, December* 3, 1903.

**Two Cases of Primary Isolated Lichen Ruber Planus of the Mouth.**—Sack describes two cases in which the appearance of flat, white, progressively increasing patches on the tongue gave rise to the suspicion of syphilis. Under observation, however, the condition was correctly diagnosed as lichen ruber planus. There was no involvement of the skin and the lesion gave rise to no symptoms. In case the usual attendant evidences of syphilis, such as glandular enlargement, eruption, etc., are absent the diagnosis is aided by the facts that the patches of lichen are sharply circumscribed, with distinct borders, and the adjoining mucous membrance is healthy, while opposite conditions prevail in syphilis. The lichen patch is hard, resisting, and never loses its porcelain-like mosaic appearance, which indicates its origin from separate papillæ. The treatment is less satisfactory than when the disease is situated on the skin, and particularly the usually effective arsenic loses its value when the lesion is confined to the mucous membranes.

**Protection against Röntgen Rays, and Their Dosage.**—Levy Dorn says that this question is constantly acquiring greater significance, and that undoubtedly legal restriction will soon be imposed on users of the Röntgen rays to prevent injury to those examined and treated. No satisfactory means of actual measurement has yet been devised, but every radiographer can make observations which will enable him to form an estimate of the power of his apparatus under the various modifications of current frequency of interruption, distance of the tube, etc. The author's rule is that the safe maximum exposure is twenty times that used for radiographing the adult pelvis. For this the plate is usually sixty centimeters distant from the tube, but the skin of the patient only thirty centimeters, so that the skin receives four times the intensity of illumination that the plate does. If the exposure necessary is two minutes, the maximal exposures will be $\frac{2}{4}^0$ of the time—that is, ten minutes. A similar calculation is to be carried out if the data should be different, bearing in mind that the intensity of the *x*-rays, like that of light, is inversely as the square of the distance. Owing to the cumulative effect of the rays, during a space of fourteen days the aggregate of the exposures should not exceed one and one-half times the maximum. It must also be remembered that inflammatory affections of the skins render it more susceptible to the rays even after the inflammation has subsided, and that young persons, mucous membranes, the face and back of the hands react very easily. Precautions for the operator himself are important but difficult to carry out. The hand should never be used as test object, a wrapped-up bone answering every purpose, and plates of lead, gauntlets of tin foil and metal screens should all be used to protect the person from exposure.

*Berliner klinische Wochenschrift, November* 30, 1903.

**Acute Sigmoiditis.**—Edlefsen gives this name to an acute localized peritonitis involving the sigmoid and frequently extending upward to the lower part of the descending colon. It is the result of prolonged fecal stagnation and is most frequently observed in puerperal women in whom the conditions are particularly favorable for its production. In general the picture much resembles a typhlitis transferred to the left side of the abdomen. The affection has the clinical features of an acute inflammatory disease and is always accompanied by pain, local tenderness and fever.

**Antituberculous Serum.**—Marmorek was led to conclude that tuberculin on injection into healthy and diseased animals did not act in the manner usually believed, but that the tuberculin merely forms a reagent or stimulus which causes the tubercle bacilli within the body to form the true toxin of the disease. This has not previously been detected because it is formed only under certain conditions present in the living body but which the conventional culture media do not imitate. By growing the bacilli on a medium containing a leucotoxic serum, obtained by injecting into calves leucocytes of guinea-pigs, certain cultural differences were observed, and particularly the scanty and late formation of tuberculin. On the other hand, a new and different toxic substance was formed. The relatively high resistance of the liver to tuberculous invasion suggested the use of liver tissue as an addition to the culture medium in order to stimulate the bacteria to toxin formation by adverse conditions. In this way a substance was produced whose identity as the toxin of the disease could be proven by the fact that it was capable of immunizing guinea-pigs to the tubercle bacillus. By injecting it into horses a serum was produced which, after encouraging results upon animals had been obtained, was tried on tuberculous patients. Most of these were cases of long standing and exhibited mainly various forms of surgical tuberculosis, but markedly beneficial results were seen. This was also true of some pulmonary cases treated, but the method has not been in use long enough to permit very extensive clinical reports.

**The Technique of Rectoscopy.**—H. Strauss describes a form of pneumatic proctoscope presenting several minor features of difference from those already in use, and discusses various points concerning the application of these instruments, which he has found to contribute greatly to the results attainable. The form of attachment of the electric bulb is more convenient than in other models and so arranged that soiling with intestinal contents is less likely. The outside of tube is graduated in centimeters so that its depth of introduction can be seen at a glance. The night before the examination, and again the next day about three hours before the time, the rectum is flushed with a liter of salt solution. The bladder is emptied and the patient placed in the knee chest position. A preliminary cocainization of the anus is frequently valuable. The chief point made by the author is that after having introduced the instrument to the depth of eleven centimeters its direction must be changed from that corresponding to the curve of the sacrum to that of a line tending to pass somewhat anterior to the promontory. Before reaching this point it may or may not be necessary to resort to inflation of the bowel by means of the hand bulb attached, but from now on it is advisable to distend the gut artificially in order to make the opening of the sigmoid flexure easier to discover. This must be sought for carefully by moving the point of the instrument about in all directions, as it is but rarely in the direct line of vision as the instrument is introduced. The author's longest instrument measures thirty-five centimeters but he rarely introduces it beyond thirty to thirty-three centimetres, at which point the normal angulation of the gut prevents further penetration.

---

**The Plague in India: A Study of the Results of the Haffkine Prophylactic.**—B. Rosalie Slaughter states that there is one indirect danger which has been realized in connection with immunity—that is, the protected, feeling that they are safe, have gone freely among those stricken with the plague, and have then attended to their various occupations, and in this way have spread infection. The writer sums up the benefits of the prophylactic as follows: (1) It renders a person immune for three months. (2) It acts within twenty-four hours. (3) When inoculation is given in incubation stage of disease—that is, before signs of plague appear—it has, in many cases, the power to abort the disease. (4) Inoculation has no effect on other diseases, except, possibly, eczema, which appears to be benefited by it. (5) Inoculation confers a high degree of immunity, and greatly reduces the number of plague attacks. (6) When, in spite of inoculation, a person is attacked, his chances of recovery are greatly increased.—*Bulletin of the Johns Hopkins Hospital.*

# Book Reviews.

THE AFTER-TREATMENT OF OPERATIONS. A Manual for Practitioners and House Surgeons. By P. LOCKHART MUMMERY, F.R.C.S.Eng., B.A., M.B., B.C.Cantab., Demonstrator of Operative Surgery, St. George's Hospital; Late Senior House Surgeon, St. George's Hospital. New York: William Wood & Co., 1903.

THIS very pleasing little book of two hundred pages will be welcome to all. Good manuals are rare and few of the class of this publication are in existence. This book should be as welcome in America as in England, for it is based on observations made, and treatments outlined, in both countries. The introduction treats of the important problem of posture after operation. Much attention has been devoted to this detail by prominent American authors, and students as well as house surgeons may read these pages with profit. The author modestly states that the manual is for the use of these two classes, but it will be found valuable to all operating surgeons. One of the most useful features of the book is the full differential diagnosis given between postoperative rashes and those of an infectious character. As is eminently proper, much space is given to the post-operative care of patients who have undergone thoracic operations of all kinds. Full abstracts are given from Dr. H. Campbell's book on respiratory exercise, which are directed toward the obliteration of post-empyemic cavities. Appropriate attention is given to the preparation of foods, especial care being devoted to the preparation of grape sugar—a form of "raisin tea" being commended. Beef tea, as usually prepared, is satisfactorily condemned. In fine, the manual is well worth reading.

THE MEDICAL NEWS VISITING LIST, 1904. Philadelphia and New York: Lea Brothers & Co., 1903.

THIS new edition of 1904 is, like its predecessors, compact, but containing in its small compass a great deal of valuable information. Directions are given for keeping a visiting list. Various notes are given as to the signs of dentition, the calculation of the day of confinement, tables of the ordinary weights and measures, the metric system, and its equivalents in the ordinary weights and measures, thermometric scales, methods of examination of the urine, poisons and antidotes, a table of doses, and therapeutic reminders. The book allows for the entries of thirty patients a week. Besides the regular daily visiting list, there are sections for general memoranda, obstetric engagements, vaccinations, and cash account. The binding might be improved upon, as the material of which the covers are made is a poor substitute for leather. However, this is no doubt of sufficient durability for the required purpose.

THE PHYSICIAN'S VISITING LIST FOR 1904. Fifty-third Year of Its Publication. Philadelphia: P. Blakiston's Son & Co., 1903.

THIS list presents, in convenient form, spaces for noting the various events of daily routine; such as calls to be made, obstetric and vaccination engagements, addresses of patients and nurses, etc., and a system of symbols to be used to shorten the manual labor of notation, tables of doses, thermometric equivalents, etc., are appended.

GYNECOLOGICAL NURSING. By NETTA STEWART, Sister in the Extra-Mural Gynecological Wards of the Royal Infirmary, Edinburgh. New York: Wm. Wood & Co., 1903.

THE writer has brought together in this convenient handbook the essentials of gynecological nursing. Among the subjects discussed are the examination of patients, the vaginal douche, tampon, and plug, the use of the catheter, the washing out of the bladder, the examination of the bladder and rectum, and various gynecological operations with preparations for the same.

PAUL GUTTMANN'S LEHRBUCH DER KLINISCHEN UNTERSUCHUNGSMETHODE FÜR DIE BRUST- UND UNTERLEIBSORGANE. Herausgegeben von Dr. FELIX KLEMPERER, Privatdocent an der Universität in Berlin. Neunte verbesserte und vermehrte Auflage. Berlin: August Hirschwald, 1904.

THE popularity of this book which made it a favorite for over twenty years until the author's death in 1892 caused it to fall behind in the race, will, undoubtedly, be restored to its former mark now that its revision has been undertaken by such competent hands. Through Klemperer's labors it has become once more representative of the teaching of the hour, while the systematic arrangement and clarity of style of its earlier days still remain to attract another generation of readers. The sections on general examination and on the examination of the chest are the strongest in the book and form an admirable guide for the student of physical diagnosis. But some of the other chapters, notably those on the blood and urine, seem to suffer greatly through the absence of illustrations, which are almost a necessity in the discussion of these topics. In spite of this defect, however, the book has an inherent vigor and charm that will no doubt restore it to its former preëminence.

COMPENDIUM DER OPERATIONS- UND VERBANDSTECHNIK. Von Dr. EDUARD SONNENBURG und Dr. RICHARD MÜHSAM. Zweiter Teil. Specielle Operationstechnik. Mit 194 abbildungen im Text. Berlin: August Hirschwald, 1903.

THIS, the second volume of the author's handbook of operative surgery, is devoted to regional surgery. The range of topics treated covers most of the important subjects, but owing to the small size of the book their discussion is necessarily somewhat sketchy and incomplete. Everything stated is, however, thoroughly modern in principle and detail, while many minor variations which appear from time to time make its perusal interesting to American readers. The most noteworthy deviation from our methods is noted in the section on appendicitis, where we find that the appendix is removed both in acute and chronic cases, through an incision parallel with Poupart's ligament and not differing greatly in position from the usual Bossini incision. The illustrations throughout are fairly good, and the little volume may be recommended as presenting an agreeably written synopsis of the German surgery of to-day.

A MANUAL OF BACTERIOLOGY. By HERBERT N. WILLIAMS, M.D., Professor of Pathology and Bacteriology, Medical Department, University of Buffalo. With ninety-nine illustrations. Third edition, revised and enlarged. Philadelphia: P. Blakiston's Sons & Co. 1903.

THAT this manual should have reached a third edition in an unusually short space of time is not surprising, for it possesses a degree of practicality not commonly found in books of its class. Realizing that for the purposes of the student there are other subjects which demand and deserve a greater amount of time than bacteriology, the author has made his method of discussing the subject bear as much as possible on the broader departments of general medicine and surgery, and the direct application of bacteriologial methods to their development and study. Accordingly, we find that the chapters on the bacteria of the normal body, of the soil, air, water and foods, on bacteria in disease, toxins and immunity, disinfectants and antiseptics, and the preparation of surgical supplies, are all extremely serviceable. Many new illustrations have been added to this edition, as well as an introductory review of the history of bacteriology.

A TEXTBOOK OF PATHOLOGY. By ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania, Physician to the Philadelphia Hospital; Physician to the Pennsylvania Hospital, Philadelphia, etc. Fourth edition. Thoroughly revised. Philadelphia, New York, and London: W. B. Saunders & Company, 1903.

THE first edition of this work appeared in the autumn of 1898 and the third in 1900. In the three years which have passed since then, there have been many changes in medical theories, some facts have been established, and some supposed facts have been shown to be hypotheses. Among the subjects in which the most extensive revision has been made are typhoid fever, tuberculosis, dysentery, yellow fever, hæmatology, and immunity. A chapter on the technique of pathological methods has been added in this edition. In addition to the illustrations in the text, some of them in colors, there are seven well-executed chromolithographic plates. Dr. Stengel is a good writer, thoroughly master of his subject, and his work is one which the student of pathology may safely accept as a trustworthy guide.

THE MEDICAL EPITOME SERIES. ANATOMY. A Manual for Students and Practitioners. By HENRY E. HALE, A.M., M.D., Assistant Demonstrater of Anatomy, College of Physicians and Surgeons, Columbia University in the City of New York, Clinical Assistant in Pediatrics, Vanderbilt Clinic, New York. Series edited by V. C. PEDERSON, A.M., M.D., Instructor in Surgery and Anæsthetist and Instructor in Anæsthesia at the New York Polyclinic Medical School and Hospital; Deputy Genitourinary Surgeon to the Outpatient Department of the New York Hospital; Physician in charge, St Chrysostom's Dispensary; Anæsthetist to the Roosevelt Hospital (First Surgical Division). Illustrated with seventy-one engravings. Philadelphia and New York: Lea Brothers & Co., 1903.

THE present volume adds one more to this valuable series. The book, though a small one of 370 pages, is comprehensive in all essentials. The authors have succeeded in their aim to make their work a combination of brevity, clearness and comprehensiveness. There are six parts, embracing the following subjects: Osteology, Arthrology, Myology, Angeiology, Neurology, and Splanchnology. There are seventy-one engravings interspersed through-

out the text. At the end of each chapter comes a group of questions, making the book suitable for a quizzing compend. An excellent index completes the work.

PHYSICIANS' POCKET ACCOUNT BOOK. By J. J. TAYLOR, M.D. Philadelphia: The Medical Council, 1903.

THIS little book is arranged with great simplicity, and its use will economize both space and time. It is the only single-book system on the market. Each account is made originally in ledger form, so that no posting into a ledger is necessary. The arrangement of the book enables the physician to prove that his account is correct.

PRACTICAL NURSING. By ISLA STEWART, Matron of St. Bartholomew's Hospital, London, and HERBERT E. CUFF, M.D., F.R.C.S., Medical Superintendent, North-eastern Fever Hospital, Tottenham, London. In two Volumes. Vol. II. Edinburgh and London: William Blackwood & Sons, 1903.

ALTHOUGH this is a book of only 200 pages, it is so compactly arranged that, together with the first volume, it offers an excellent résumé of the subject of nursing. Among the chapters in this second volume are those on Enteric Fever, Smallpox, Scarlet Fever; Diseases of the Respiratory, Nervous, Circulatory and Digestive Systems; Burns, Fractures, and Gynecological Nursing.

CLINICAL TALKS ON MINOR SURGERY. By JAMES G. MUMFORD, M.D., Assistant Visiting Surgeon to the Massachusetts General Hospital, and Instructor in Surgery. Harvard University Medical School. Boston: The Old Corner Bookstore, 1903.

THE writer deals here with subjects which find little place in textbooks. Among the chapters treated are those on Incised Wounds, Simple Fractures, Compound Fractures, Granulating Wounds and Varicose Ulcers, Felon, Whitlow, Paronychia, Palman Abscess, Bunions, Ingrowing Nails, Corns and Warts, and, lastly, Massage. It is a useful little volume.

LA GASTRO-ENTEROSTOMIA. Metodi Operativi Indicahioni-Risultati. Studio Critico-Clinico-Sperimentali. Ed una Statistica Originale Italiana della Gastro-Enterostomia. Pel Dott. ARISTIDE MATTOLI, Chirurgo Primaro, Direttore dell' Ospedale Civile di Tolentino. Roma: Società Editrice Dante Alighieri, 1903.

THIS volume of three hundred and thirty pages devoted to the subject of gastroenterostomy, covers every aspect of the subject most completely and offers a satisfactory résumé of what has been accomplished in this field of surgery. The historical notes have been worked up with unusual thoroughness, and throughout the book the wealth of references to the literature, including American writings, bears testimony to the care that has been devoted to its preparation. The main headings comprise a chapter on preliminary considerations such as the history and anatomy; the technique of the anastomosis and the sites that may be chosen for it; the methods of suture and substitutes therefor; the vicious circle and operative methods designed to avoid it, including an ingenious method of obliterating the different loops devised by the author; the indications for the operation and its results; and finally, a complete statistical conspectus of all Italian gastroenterostomies. The operation has been done in Italy ten hundred and twenty-eight times, with a total mortality of 20.23 per cent. Somewhat more than half the cases were operated for non-malignant causes and of these the mortality was 10.50 per cent. The author devotes much space to the Murphy button and allied means of facilitating the anastomosis, but ends by concluding in favor of the suture. He does not take the same enthusiastic stand in regard to gastro-enterostomy for gastric ulcer that many writers, notably some of the English surgeons, do; but considers the operation indicated in advanced cases with prolonged hæmatemesis that have resisted medical treatment. In duodenal ulcer or stenosis, however, he considers the operation indicated as soon as the diagnosis is made.

Altogether the book is most pleasing and should be in the hands of all those interested in this branch of operative work.

MODERN SURGERY, General and Operative. By JOHN CHALMERS DACOSTA, M.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital and to St. Joseph's Hospital, Philadelphia. Fourth Edition, rewritten and enlarged. Philadelphia, New York and London: W. B. Saunders & Company, 1903.

IT is three years since the third edition of Dr. DaCosta's well-known and appreciated surgical treatise was published, and the author has improved the opportunity which a new issue offered to incorporate in his work an account of all the advances in surgery which have been made in that interval. The book is of inconveniently large size, nearly eleven hundred octavo pages, and might, for the benefit of the reader, be divided into two volumes. The index is long, but there are some omissions which ought not to exist in a work intended for reference as well as connected study.

A MANUAL OF THE PRACTICE OF MEDICINE. By A. A. STEVENS, M.D. Sixth Edition. Philadelphia, New York and London: W. B. Saunders & Co., 1903.

THAT this work already has many warm friends is shown by the need for six editions in eleven years. The present one has been revised and, in many places, particularly in the section on Diseases of the Digestive System, has been entirely rewritten. Although the size, shape, and binding of this volume combine to make it in fact, as well as in name, a manual, it should not be inferred from this that it belongs to the large class of "compends" or "epitomes." It is an up-to-date handbook of the practice of medicine, conveniently arranged for ready reference, and presenting the various subjects in what the author aptly describes as an "assimilable form."

ATLAS OF THE EXTERNAL DISEASES OF THE EYE, including a brief treatise on the Pathology and Treatment. By Prof. Dr. O. HAAB of Zurich. Authorized translation from the German. Second Edition, revised. Edited by G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, etc. Philadelphia, New York and London: W. B. Saunders & Co., 1903.

DR. DE SCHWEINITZ has, for a second time, given us an excellent and exact translation of Professor Haab's exhaustive little Atlas of the Diseases of the Eye. There have been added a few chromo-lithographic plates, most of which have reference to morbid corneal or lid conditions, in their varied forms. For those not fortunate enough to see, in daily practice, cases of external diseases of the eye in their varied and manifold forms, this complete and compact atlas, with its plates, supplies as near as may be the lack of clinical study.

PHYSICS AND INORGANIC CHEMISTRY. By Dr. A. McGLANNAN. Philadelphia and New York: Lea Brothers & Co., 1903.

THIS book, like the others of the "Medical Epitome" series, gives a good deal of information in a small space, but so much compression has been necessary that the result reminds us of the dried meat left after extracting the flavoring juices. This is not, however, the fault of the author, for he has covered the ground in clear and terse language; but it is a fault inherent in works of this class, and one which becomes particularly glaring in dealing with certain subjects which do not lend themselves kindly to such treatment.

GESAMMELTE ABHANDLUNGEN ÜBER ZUCKERBILDUNG IN DER LEBER. Von Prof. Dr. J. SEEGEN. Berlin: August Hirschwald, 1904.

THIS is a collection of thirty-six dissertations on the glycogenic function of the liver and allied subjects, which have appeared in various physiological journals during the past thirty years. They are arranged in chronological order to show the various steps by which the author has been enabled to formulate what is now the generally accepted theory as to the relation of the liver to the sugars of the body, and detail the bitter opposition his views met with at the hands of the advocates of Pavy's teaching. Not the least interesting part of the book is the introduction, in which the octogenarian author reviews his struggles at the time when he was the sole upholder of principles now universally accredited, and also indicates the lines of investigation still necessary to make the complex problem wholly clear.

DIE ENTSTEHUNG DER ZUCKERKRANKHEIT UND IHRE BEZIEHUNGEN ZU DEN VERÄNDERUNGEN DER BLUTGEFÄSSDRÜSEN. Von Dr. A. LORAND. Berlin: August Hirschwald, 1903.

THE author believes that toxins emanating from the thyroid gland are concerned in the production of diabetes. If the thyroid gland alone is diseased, temporary and alimentary forms of glycosuria appear, but if there is an associated lesion of the pancreas, permanent diabetes follows. Antithyroid preparations appear to exert a beneficial effect in cases of diabetes.

A COMPEND OF DISEASES OF THE SKIN. By JAY F. SCHAMBERG, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic, etc. Third edition, revised and enlarged, with 106 illustrations. Philadelphia: P. Blakiston's Sons & Co., 1903.

IF Dr. Schamberg had not originally written a pretty good quiz compend, to which series this belongs, the book would not now be enjoying the popularity which it has attained as it comes out for the third time. It is small and condensed, and serves the purpose only for which it was intended, but serves this purpose well.

# Society Reports.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, Held November 9, 1903.*

Dr. WILLIAM HALLOCK PARK IN THE CHAIR.

**A Case of Pernicious Anæmia Showing a Megaloblastic Crisis.**—D. S. D. JESSUP presented slides and photographs of the blood of a case of pernicious anæmia which had been under observation for six weeks. The red cells at first were one million one hundred and fifty-two thousand, and hæmoglobin 25 per cent. Ten days later the red cells had fallen to nine hundred and sixty-eight thousand and the hæmoglobin to 15 per cent., and the number of megaloblasts was much increased, so that on a differential count of the white cells, 17 per cent. were megaloblasts, giving one thousand and twenty to the cubic millimeter, on the count of six thousand white cells. A fortnight later thre was a marked increase in the red cells and amount of hæmoglobin, and a disappearance of the megaloblasts

Dr. F. C. WOOD demonstrated slides and photographs from a case of lymphatic leukæmia with a marked normoblastic crisis occurring about ten days before death. The number of normoblasts to the cubic centimeter was estimated from the smears at about one-tenth of the red cells present. As the red cell count was about four hundred and ninety thousand, he thought that the normoblasts were at least forty thousand to the cubic centimeter. In this case the normoblastic crisis was certainly not of prognostic value, as is stated in many textbooks on the subject.

Dr. WOOD also demonstrated series of smears from cases of pernicious anæmia, showing mitotic figures in the megaloblasts, and also from cases of myelogenous and lymphatic leukæmia, showing mitoses in the normoblasts. In his experience such appearances were of no special diagnostic or prognostic value, as some of these cases had survived for over a year after the appearance of the mitotic figures in the blood, and some had died in a few weeks.

**The Diagnostic Value of Cultures in Horses Suspected of Glanders.**—Dr. LETCHWORTH SMITH said that the purpose of his paper was to bring before the society the results of a number of examinations made upon the cadavers of horses thought to have glanders, which were killed after being tested with mallein, referring more particularly to the temperature element. He said the reaction to mallein included three separate points, as follows: (1) A general reaction, shown by the loss of appetite, dejected appearance, etc. (2) A local reaction the appearance of hot, tender swelling at the site of injection, lasting for several days. (3) A rise of temperature. The elevation of temperature was from 2.7° to 7.2° F. The temperatures were taken five times during the day preceding the injection, and again five times the following day. In estimating the rise of temperature during the test it seemed fair to compare the average of the temperature taken before the injection with the average taken after. The following is a summary of Chart No. 4 which he presented:

Out of forty-three cases, eight showed a rise of 2° C. or more. Of these, three showed lesions which were interpreted as glanderous, besides yielding the bacillus; two showed lesions believed to indicate glanders, but from which they were unable to isolate the organism; of the remaining three, one seemed entirely normal, one showed some areas of grayish consolidation which might have been glanderous, and one showed only a single lung nodule of doubtful character. Out of the forty-three cases, twenty-two showed a rise between 1° and 2° C. Of these, six gave both pathological and bacteriological evidences of glanders; seven showed pathological evidence only; nine gave no indications. Out of the forty-three cases, in thirteen the rise was less than 1° C Of these four yielded the bacillus, five showed suspicious lesions, and four were considered negative.

If a conservative course had been followed by the Board of Health last spring, *i.e.* considering as negative all cases which failed to show a rise of 2° C., ten horses from which the bacillus was recovered, and twelve others which were probably cases of glanders, would have remained alive and possible sources of infection in various parts of New York City. He regretted that more reliance could not be placed upon the negative findings. He said that a lack of knowledge of conditions in the horse which might simulate glanders was a possible source of error. The mallein used in this work corresponded in preparation quite closely with the suggestions made by Ravanel. His experience in this work during the past summer seemed to support the position of those who considered mallein a valuable diagnostic aid. It was open to argument as yet whether they were justified in destroying horses which showed no signs of glanders except a mallein reaction.

Dr. WILLIAM H. PARK said he had recently heard of a case occurring in Bridgeport. A horse was supposed to have glanders, and was injected with mallein with a slight reaction following. The horse was not condemned. Shortly after, the horse showed more definite symptoms, and at the same time the owner of the horse and his daughter became sick with glanders. The horse was then killed and presented the usual lesions, although they were not well defined. The local physician and veterinary claimed to have found the bacillus. The daughter had not been in contact with the horse, only driving behind it. It was probable when the horse sneezed or coughed she inhaled the bacillus.

**Unusual Case of Alcoholic Multiple Neuritis.**—Dr. HARLOW BROOKS read this paper. The patient was a woman, fifty-two years old, born in Russia, and had been in this country two and a half years. There was apparently no tuberculous, specific, neurotic, or malignant taint in the family. She was born at full term, being the twelfth child. She began to walk when two and a half years old. She had smallpox when five years old. She had frost bites on her toes when eight years old. Between the ages of eleven and fifteen attended school, when she left to assist her mother in housework and in attending to her business (tavern). She worked very hard, rarely going to bed before midnight and, at times, getting up at 2 A.M. Began to menstruate at seventeen, then it stopped for one year, reappearing when she was eighteen; since it had been regular, painless, rather profuse, lasting seven days. She married at nineteen. She began to drink whiskey at the age of nine years, and since had been accustomed to take two or three drinks a day, but never to intoxication.

When thirty-five years old she was frightened after a confinement, and soon developed twitching pains in the small of her back, referable to the spine, lasting a few minutes only. These twitching pains came and went for two years, when she was free from pain for a year; then she noticed that her ankles became painful and swollen. One year later she began to suffer from attacks of diarrhœa followed by periods of constipation, from which condition she never got complete relief. When forty years old she again got frightened after childbirth and a headache ensued which lasted one and a half years. When forty-one years old she fell and produced a miscarriage which was accompanied with considerable bleeding. At forty-two a callosity formed, making walking difficult. She now began to notice tremors in both legs, coming on two or three times a day; this condition lasted a number of years. About two and a half years ago the patient noticed, when walking on board ship, a peculiar sensation, as if something soft was underlying, like a carpet or wadding. Two years ago the patient worried a good deal over the death of a son and got hot flashes over the body, for which she took cold baths,

finally developing lumbago. She then became weaker and weaker, pains in the legs became more severe and persistent, she could not control her urinary functions, and she frequently would wet the bed.

Pains of a sticking character set in about nine months ago in the larger joints of the body. The wrists were free from pain, but the fingers got stiff and numb. She was very weak and had to remain in bed. Legs and feet weak and pains very great, especially in the legs. Pains in back were very bad and it was impossible for her to stand straight. Pains would start in the feet and involve the arms and shoulders. She could not lift hand or foot. She remained in bed six months. She then improved until May 18, 1903, when she was taken to Mt. Sinai Hospital; she then could sit up without help. She had diarrhœa and passed water very frequently. The diarrhœa was accompanied by tenesmus. She denied girdle sensations and diplopia and stated that her dexterity of hands had been impaired for eight months. There was loss of weight, and paræsthesia in hands eight months ago.

Examination showed the nutrition poor, muscles flabby, myototic irritability wave-like, panniculus adiposus and small skeleton. There was slight Romberg, slow gait, and patient had to stop and hold on to near objects; the gait was ataxic, paretic. There were no visible glandular enlargements, and no enlargements of the ends of the bones. There was no increased resistance to passive motion in arms or thighs. Position of arms and forearms was normal and articulations were normal. Reflexes were present and exaggerated. Motor power diminished in flexors of thighs. Ankle-joint was deformed from an old process; the foot was turned in valgus position. The great toe was abducted, making the metatarso-phalangeal articulation prominent. With patient in bed there was a slight foot drop. There was inability to recognize the number of fingers placed on the skin in both upper and lower extremities. Temperature sense was normal. The knee-jerk was much diminished and sometimes entirely absent. Babinski's sign slightly elicitable on left side. Decubitus occurred on October 2 and death on October 30.

At the autopsy the brain showed marked œdema of pia-arachnoid, membrane moderately congested, not thickened or adherent. Arteries at base showed marked atheroma, with fatty degeneration. Ventricles were dilated with clear serous fluid, with petechiæ in roof of left lateral ventricle. Cortical gray matter was thick and regular. Brain tissue was soft and œdematous. No gross changes appeared in the retina. Membranes of cord showed nothing abnormal. The cord was soft without any gross changes. The great sciatics apparently showed fibroid increase. The posterior tibial muscles showed replacement atrophy. The cause of death was a chronic interstitial nephritis with cerebral œdema, general arteriosclerosis of marked degree, terminating peripheral neuritis probably of alcoholic origin.

The viscera showed the lesions common to the indulgence in alcohol to excess. Changes of a surprising nature were noted in the brain, spinal cord, and posterior root, ganglia and nerve roots. There were degenerations throughout the entire motor areas. There were descending degenerations in both the crossed and pyramidal tracts. Degenerated fibers were found in the cervical levels abundantly in the anterior pyramids, in the crossed pyramidal tracts and in the descending cerebellar tracts and column of Goll. In the lumbar and sacral regions both columns of Goll and Burdach were extensively degenerated, but less marked in the crossed and direct pyramids. There were no distinct areas of sclerosis. Both anterior and posterior nerve roots were extensively degenerated. Degenerated fibers were found to be as numerous in the anterior as in the posterior nerve roots. Peripheral nerves showed extensive neuritis, more marked in the small than in the large trunks. He stated that the most interesting part was the presence of a descending degeneration characterized by a cellular degeneration and one of the axis cylinder process. In textbooks it was stated that alcohol had a selective tendency for the peripheral nerves but, from his findings and study of other cases, he believed the theory was very questionable.

Dr. MAX G. SCHLAPP said that two years ago he showed a case of alcoholic neuritis in which the degenerative changes occurred in the cortex, not confined alone to the motor areas but scattered throughout. The conditions differed clinically in that this patient had mental symptoms. There was a perineuritis with alcoholic dementia. He referred to the different methods of staining used in finding the changes, and said that, in the early cases, only the myelin substance was destroyed and the changes would not be marked. If the axis cylinder broke down the changes then could not be recognized early with the method used in staining the myelin substance. Therefore, he believed the reasons the lesion had not been detected before was because the investigator examined by other than the osmic acid method. He did not believe alcohol had a selective action on the sensory neurons, but that it did on the motor neurons. He said the important fact brought out by Dr. Brooks was that the degenerative changes were not confined to the peripheral nerves, but were scattered throughout the central nervous system.

**Demonstration of a Patent Foramen Ovale and a Case of Serositis.**—Dr. J. E. WELCH reported the following cases:

CASE 1. The patient was an Italian, about sixteen years old, who was admitted to the hospital suffering from dyspnœa and œdema of legs, which gradually spread over the body. He had pain over the precordial region, which was so great that he requested an Italian friend to give him an instrument with which he could commit suicide. The patient died and, at the autopsy, there was found a heart greatly enlarged, especially on the right side, and dilatation. Over the surface of the heart there was recently developed fibrin, especially over the right auricle and ventricle and both apices. The valves were very much thickened, especially the tricuspid and mitral. There was an enormous sized foramen ovale one and one-half inches in diameter, and a smaller opening was found just beneath it.

CASE 2. In 1846 a case was reported in which were the following findings: An obliterative pericarditis, pleurisy with adhesions obliterating both pleural cavities, an inflammation of the peritoneum causing much thickening of the capsule of liver, of spleen, and a general thickening of the whole peritoneum. There was ascites which preceeded the œdema of the legs. The theory advanced was that the condition started primarily in the heart and this inflammation spread to the pleural surface and later on extended to the abdominal cavity and caused the changes found there. He said that since that time many cases had been reported in various places. In the January number of the *American Journal of the Medical Sciences* Dr. Aloysius O. J. Kelly reported thirty-eight cases; the constant features of these being the ascites, the thickened serous membranes throughout with an obliterative pericarditis. The principle point was that the ascites appeared before the œdema in the legs. In the great majority of the cases there were no changes in the liver or spleen that could account for the ascites.

The patient was a man, thirty-five years old, and single. He gave a history of alcoholism, taking five or six drinks of whiskey a day, one or two before breakfast; he also drank enormous quantities of beer. He had gonorrhœa several times. Twelve years ago he had chancroids, which was followed by a suppurating inguinal adenitis. During last November he was seized with cramps, the pains extending over the body, becoming localized in the upper part of the abdomen, where swelling and tenderness appeared. He entered Bellevue Hospital, and the physical examination revealed some ascites with

swelling of the legs. The heart was rapid and feeble in action. There was some increase in tension in the arteries. Cyanosis was present. There was no jaundice. Directly after he entered the hospital a general rash appeared over the body and it was learned then that he had had a chancre, which had only healed a few weeks before admission. He was dismissed from the hospital December 12, 1902, and then was treated in the dispensary until March, when he had such a swelling of the abdomen, pain and dyspnœa and œdema of the legs that he was readmitted three days later. Shortly after he was tapped, and a large quantity of fluid withdrawn. He was tapped at intervals until just before death occurred. At autopsy the membranes of the brain were not examined. There was found an obliterative pericarditis. The right pleural cavity contained firm masses of adhesions and 300 cm. of fluid. The left cavity had many adhesions and contained about three litres of serum. There was also a perihepatitis, the so-called "sugar-coated liver." There was a generally diffused thickening of the peritoneum. He said a curious feature was the proliferative change with complete absorption of the great omentum, the gastrocolic omentum being completely absent, and a free communication being established between the two peritoneal cavities. There were tubercles in the lungs, in the mediastinal glands and some in the spleen. None were found on the peritoneal surface or in the liver. The liver was cirrhotic. The cause of the conditions found he stated to be alcoholism, syphilis, and tuberculosis, all occurring in the same patient.

Dr. EMANUEL LIBMAN said that in autopsies upon the last one hundred cases there were thirteen in which the foramen ovale was found more or less open; the ages of the cases varied from three months to three or four years. In none of them were there clinical symptoms referable to the foramen ovale.

Dr. HARLOW BROOKS said that the condition had not been traced to a patent foramen ovale. Such a diagnosis could not be made out in this case. It was thought to be a double mitral lesion or possibly a tricuspid one.

**A Group of Seven Cases of Paratyphoid Infection.**—Dr. GEORGE A. TUTTLE detailed the histories of seven cases occurring in a tenement-house in this city caused by drinking water taken from a large wooden tank. This tank was on the roof and was allowed to become emptied before more water was added; as a result, the last of the water drawn was often filthy, almost black, and with a very bad odor. Out of thirteen people living on this top floor seven became infected.

**Preliminary Note on Precipitins Formed by Injecting Animals with Globulin of Normal and Diphtheritic Antitoxic Horse Serum.**—Mr. J. P. ATKINSON of the Research Laboratory of the New York Board of Health presented this communication. He said that about one year ago it occurred to him that animals injected with globulin of normal horse serum and with the globulin of diphtheritic antitoxic horse serum might develop antibodies which would act as specific precipitins for normal serum globulin and antitoxic horse serum globulin respectively, thus affording a method for separating the active substance in diphtheritic antitoxic serum from the inactive substance. The globulin solutions were prepared from normal and diphtheritic antitoxic sera by precipitation with magnesium sulphate, and were purified by solution and reprecipitation until free from serum albumin and were finally freed from magnesium sulphate by dialysis in the presence of chloroform.

Two rabbits were selected for immunization, one being injected with the solution of normal globulin, the other with the solution of antitoxic globulin. After a number of injections had been given each rabbit, they were bled and the sera from the clots were tested against diphtheritic antitoxic serum with the following result: Two samples of diphtheritic antitoxin were diluted so that 1 c.c. of the dilution contained $\frac{1}{10}$ unit of antitoxin. Two portions of 5 c.c. each were taken from each dilution and to them was added serum from each rabbit, so that the globulin in each horse serum was acted on by what we may call an anti-normal globulin serum and a mixed antiserum which should react for both normal and antitoxic globulin. After precipitation had taken place the precipitates were filtered off. An amount corresponding to 1 c.c. of the original serum dilution from each filtrate was mixed with ten fatal doses of diphtheria toxin and injected subcutaneously into guinea-pigs; all the guinea-pigs died within forty-eight hours. The antitoxin dilutions were tested against diphtheria toxin to make sure that without the presence of the rabbit serum they would protect against ten fatal doses of diphtheria toxin. The toxin was also tested and found to be of the estimated strength. The action of both rabbit sera was again tested. In this test twice as much antitoxin as was necessary to protect against ten fatal doses of toxin was used instead of the exact neutralizing solution. The result was the same; both guinea-pigs injected died within forty-eight hours. It will be seen by these tests a specific antibody differentiating between normal globulin and antitoxic globulin was *not* formed, for the rabbit injected with normal globulin solution produced precipitating substances for the antitoxic globulin. One would infer from the results of these tests that normal globulin and diphtheritic antitoxic globulin are affected by a common precipitin while differing in the molecular arrangement through which neutralization of diphtheritic toxin occurs. It also added to the belief that diphtheritic antitoxin was of a proteid nature.

Experiments were made, he said, to determine whether the globulin precipitating serum would throw down the antitoxin from the toxin-antitoxin and have the toxin free. It did not do this and thus showed a strong combination that existed between the toxin and antitoxin. Whether the toxin-antitoxin combination, as well as the free antitoxin, was precipitated, or whether it was left in solution, was being now determined.

## Books Received.

*While the* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

THE PHYSICIAN'S VISITING LIST, 1904. 16mo. P. Blakiston's Son & Co., Philadelphia, Pa. Price, $1.00.

THE MEDICAL RECORD VISITING LIST OR PHYSICIAN'S DIARY, 1904. New revised edition. 16mo. William Wood & Company, New York. For 30 patients, $1.25; for 60 patients, $1.50.

SYLLABUS OF LECTURES ON PHYSIOLOGY. By WILLIAM H. BIGLER, A.M., M.D. Second edition. Revised and enlarged. 12mo, 205 pages, flexible. Boericke & Tafel, Philadelphia, Pa.

DIE FUNKTIONSPRÜFUNG DES AUGES UND IHRE VERWERTUNG. Von Prof. Dr. O. SCHWARZ. 8vo, 322 pages. S. Karger, Berlin, 1904.

PATHOLOGIE UND THERAPIE DER RACHITES. Von Dr. WILHELM STOELTZNER. 4vo, 279 pages. S. Karger, Berlin, 1904.

ÜBER DIE PROGNOSE DER SYPHILIS. Von Dr. G. MAYER. 8vo, 87 pages. S. Karger, Berlin, 1904.

DIE ERSTEN ZEICHEN DER NERVOSITAT DES KINDESALTERS. Von Prof. H. OPPENHEIM. 8vo, 38 pages. S. Karger, Berlin, 1904.

LES TROUBLES GASTRIQUES DANS LA TUBERCULOSE PULMONAIRE CHRONIQUE. Par le Docteur E. PASQUIER. 4to, 134 pages. G. Steinheil, Editeur, Paris, 1903.

THE TENEMENT-HOUSE PROBLEM. By various writers. Edited by ROBERT W. DEFORREST AND LAWRENCE VEILLER. In two volumes—472 and 516 pages. 8vo. The Macmillan Company, New York.

ELEMENTS OF SURGICAL DIAGNOSIS. By A. PEARCE GOULD, M.S., F.R.C.S. 16mo, 667 pages. Third edition, revised and enlarged. W. T. Keener & Co., Chicago, 1903. Price, $2.00 net.

# INDEX.

Diabetes, bronzed, 318.
Diabetes insipidus, strychnine in, 347.
Diabetes mellitus, albuminuria in, 265, 949, 1026; interrelations of, with other states, 736; lipæmia in 735; oat cure in, 548; operations in, 547; relation of glycosuria to, 17; relation of islands of Langerhans to, 447; relations of, to other constitutional states, 667; relation of, to tuberculosis and arteriosclerosis 870; skin diseases in, 307; staphylococcomyosis in, 144.
Diagnosis, inspection of the teeth and gums as an aid to, 418; laboratory aids to, for the general practitioner, 677.
Diaphragm phenomenon, the Litten, 212.
Diarrhœa, etiology, diagnosis, and prevention of infantile, 758; infantile, bacillus dysenteriæ in, 731; pathology of summer, 111; treatment of infantile, by gelatin, 510.
Diazo reaction, experiments with the, 110; yellow, 229.
Diefendorf, A. R., early symptoms of dementia præcox, 453.
Diet of bread and fruit, effects of, on high blood-pressure, dropsy, and obesity, 692.
Digestion, salivary, in the stomach, 659.
Digitalis, dosage of, 637.

Diller, Theodore, hemiplegia with aphasia occurring during the course of typhoid fever in a boy aged five years, 991.
Diphtheria, and scarlatina, borderland of, 937; antitoxin treatment of, 228, 988; bearing of mild types of, on the public health, 869; diagnosis and management of, in the country, 710; duration of quarantine in, 796; general infection with the bacillus of, 267; histone in, 707; pencils as spreaders of, 249; periodicity of, 497; poison components of the toxins of, 589; prophlyactic use of antitoxin in schools, 708; protection to the examiner in cases of, 545; spread of, 624; striking demonstration of the protective value of the antitoxin of, 782; therapeutic suggestions in, 145; value of confirmatory cultures in, 467.
Diplegia, cerebral, 877.
Disappointments of the surgeon, some of the sources of the, 714.
Disinfectants, standardization of, 458.
Dislocation, congenital, of the hip, 276
Dispensary law in New York State, working of the, 499; problem in Philadelphia, 858.
Diuretics, influence of, on the excretion of chlorides, 784.
Diver's palsy, 1016.
Diverticulum ilei, patent, 933.
Doctors' building, 705.
Drainage, principles in, 1015.
Drinking water, purification of, 193.
Dropsy, idiopathic or essential, of childhood, 471; intermittent, cured by iodoform-glycerin, 510; mode of production of cardiac, 738.
Drugs, crude, from domestic sources, 223; in children's practice, 456.
Drug eruption, a new, 516.
Drug habits, ergot in, 676; in England, 580; increase of, 221, 777.
Dunning, L. H., treatment of the pedicle in ovariotomy and salpingo-oophorectomy, 492.
Duodenum, perforating ulcer of the, 632.
Dust from buildings in process of demolition, 261, 861.
Dysentery, a septicæmia, 625; agglutination of bacilli of, by normal blood, 948; amœbic 194, 753; antitoxin of, 1027; etiology of, 910; etiology, diagnosis, and treatment of, 74; in children, bacteriology and pathology of, 675; typhoid fever in relation to, 779.
Dysmenorrhœa, etiology of membranous, 989; nasal, 589, 789; surgical treatment of, 1025.
Dyspepsia, 707; brain-strain, 752; formula for the relief of, 800; milk diet and ordinary diet in, 268; reformatory club for, 659.
Dystrophy, case of muscular 878.

E

Ear, a manometer, 333; abuse of inflation and massage of the middle, 427; catarrh of the middle, from enlarged tonsils, 377; importance of surgical treatment of chronic suppuration of the middle, 666; inflammation of the middle, in children's diseases, 629; mycosis of the meatus, 948; operative treatment of suppurative inflammation of the middle, 149; peculiar symptoms following a radical operation on the, 712; rheumatic perichondritis of the, 757; sclerosis of the middle, 267; some unsuccessful cases of surgery of the, 556; treatment of chronic disease of the middle, 754; tuberculosis of the middle, 67.
Ear-grafting, 824.
Eclampsia, morphine in, 829.
Eczema cured by measles, 613.
Education and birth rate, 20.
Eggs, dietetic value of, 828.
Ehret's disease, 511.
Einhorn, Max, the art of increasing and diminishing the bodily weight at will, 91.
Electrical congress, international, at St. Louis, 945.
Electricity, current classification and nomenclature, 595; in general practice, 841.
Electrodes, new, 590.
Electromotor, accident attending the use of, 749.
Electrotherapy in nervous diseases, foundation of, 787.
Elliot, Arthur R., cyclical albuminuria, 926.
Emotions, bearing of, on mental derangements, 118.
Emphysema, etiology of pulmonary, 748.
Empyema, apparatus for the treatment of, 467; pathology and treatment of, 599.
Emulsion-albuminuria, 773.
Endocarditis, septic, 66.
Enteritis, radiotherapy in, 108.
Enteroptosis, 388; etiology of, 305; pernicious anæmia in, 108.
Epididymitis in an undescended testicle, 107; treatment of gonorrhœal, 707.
Epiglottis abscess with involvement of the cervical glands, 554.
Epilepsy, curability of, 64; daily rhythm of, 145; genesis of, 816; masked, 753; menstrual, treated by ovarian transplantation, 189; mental training in, 633; significance of convulsions in idiopathic 427; transient post-convulsive astereognosis in, 623.
Epileptic attack, some features of the, 710; seizures, frequency wave of, 656.
Epiphyseal separation, 359.
Epiphysitis, acute, simulating congenital dislocation of the hip, 226.
Epispadias, operation for, 196.
Ergot in drug habits, 676.
Erie Railroad Surgeons' Association, 700.
Erysipelas, facial, following erosions of the nasal septum, 151; intravenous injections of colloidal silver in, 804.
Erythemata as indicators of disease, 187.
Ether, ignition of the vapor of, by electric light, 28; inhaler, a modified Allis, 638.
Etherization, avoidance of vomiting after, 798.
Ethics, principles of medical, in the United States, 220.
Ethmoiditis, pathology of, 553.
Ethyl chloride narcosis, 626.
Eustachian bougie, use and abuse of the, 557.
Evans, Thomas R., gonorrhœa in women, 987.
Excreta, disposal of, in the tropics, 269.
Exophthalmic goiter, indications for operation on the thyroid gland in, 55; respiratory crises in, 68; treatment of, 593.
Exophthalmus, differential diagnosis of, 630.
Exudates, cytology of serous, 831.
Eye, adrenal extract in diseases of, 625; amber yellow glass for the, 345; arteriosclerosis in relation to certain diseases of the, 680; asepsis in operations on the, 587; diseases of, due to nasal infection, 198; hysterical, 148; hysterical affections of the, 216; influence of heredity on the, 205; iodoform to control suppuration in the, 265; knowledge of the, of use to the general practitioner, 711; large piece of glass in the orbit for twenty years, 267; lesions of the, which occur in the course of diseases of the heart, the blood-vessels, and the kidneys, 881, 884, 913; metastatic gonorrhœal inflammation of, in an adult, 346; phototherapy in diseases of the, 1020; rare manifestations of venereal disease in the, 268; subconjunctival injections in diseases of the, 93, 145; undescribed membrane of the, 705.
Eye-clinic, a peripatetic, 62.
Eyelids, method of everting the, 798.
Eyestrain, cramp of the ciliary muscle due to, 466; functional disorders due to, 736; obscure cases of, 546; rôle of, in civilization, 392; some remote effects of, 96.

F

Facial irritability, causes and significance of, 186; irritability in mental and nervous diseases, 114; nerve, landmark for the, 200.
Faciohypoglossal anastomosis, 623.
Fæces, fermentation of the, 268.
Faith cure, State law against, 614; healing in Great Britain, 739.
Fallopian tube, gumma of the, 1024.
Fat, subcutaneous absorption of, 456.
Fatty degeneration, morphology and chemistry of, 830.
Fees, how a Japanese gambler paid his doctor's, 320; prompt collection of, 1019.
Feeding, artificial, of children, 700.
Feldman, Benson M., causes, consequences, and care of injuries to the parturient canal, 530.
Femur, fracture of the neck of the, 874; twists in the, 948.
Fermentation, surgical aspects of intestinal, 1011.
Ferrous sulphate as an antiseptic and germicide, 500.
Fever and sugar excretion, 589; continued, 107; diagnosis of, 750; hydriatic treatment of, 111; protracted, in children, 951; southern, 107; treatment of, 107.
Fibrocystic tumors of the uterus, etiology of, 561.
Fibroids, abdominal hysterectomy for, 232; uterine, 355, 356; uterine, *x*-ray treatment of, 126.
Fibroma, nasopharyngeal, 154; treatment of, by physicotherapy, 167.
Filaria medinensis, life-span of, 109.
Filariasis cured by operation, 870; Porto Rico, 724; report of a case of, 474.
Finger, reunion of the severed end of a, 111.
Fisk, Eugene L., the physical basis of life, 344.

Fitzgerald, W. H., the rational treatment of mouth-breathing, 375.
Flat-foot, abuse of supports for, 273, 816; kinesotherapeutic treatment of, 510.
Floyd, Rolfe, the anatomy of portal anastomosis, 4.
Fluorescence, artificial, of living, human tissue, 215; therapeutic uses of, 989.
Fogs, London, 519.
Food, a study of amount needed, 542; inspection law, results of the, 583; preservative, a dangerous, 796.
Foot, breaking down of the, in trained nurses, 280.
Foramen ovale, patent, 1031.
Formaldehyde, disinfection by, 61; elimination of, 990.
Formalin, experiments with, 139.
Foster, B.B., report of a needle in the prostatic urethra, 775.
Fracture, bone-wiring for ununited, 279; massage of recent, 188; modern treatment of, 599; treatment of compound, 673, 757; x-ray diagnosis of, 757.
Fraenkel, Joseph, muscle tonus and tendon phenomena, 929; tumors of the fronto-medullo-cerebellar space, acoustic neuromata (central neurofibromatosis), 1001.
Fragilitas crinium, 479; ossium in the insane, 624.
France, depopulation of, 940.
Franklin, J. H., a case of smallpox in the fœtus, 377.
Fridenburg, Percy, a signal test for color blindness, 175.
Friedreich's disease, diagnosis of insular sclerosis from, 629.
Frontal bone, dislocation of one-half of the, in an infant during birth, 96.
Funnel chest, progressive, 547.
Furunculosis, treatment of, 56.

G

Gall-bladder, diseases of the, 146; indications for operations on the, 1026; treatment of perforations of the, 109.
Gallstones, biliary colic without, 267; causes of failure of operation for, 756; gastric hyperacidity in, 829; removal of, by irrigation, 669; surgical treatment of, 678; treatment of, 756.
Gangrene of the toes in a newborn infant, 836; symmetrical, a case of, 517; treatment of diabetic, of the extremities, 67.
Gant, Samuel G., the non-medicinal treatment of constipation, 653.
Gasserian ganglion, extirpation of, for neuralgia, 876.
Gastric juice, determination of the digestive activity of, 685; opotherapy, 111.
Gastritis, phlegmonous, with cancer of the pylorus, 576.
Gastoenteric atony, suprarenal extract in, 831.
Gastroenterostomy, 359.
Gastrointestinal diseases, relation of, to disorders of the air passages, 827; toxic affections in children, treatment of, 707.
Gastrophilus epilepsalis larvæ in the skin, 899.
Gastroptosis, gastric contents in, 546; medical treatment of, 629.
Gastrostomy for cancer of the œsophagus, duration of life after, 29.
Gastrotomy for extraction of twenty-five foreign bodies, 871.
General paralysis with focal symptoms, 119.
German Emperor, throat trouble of the, 777, 781, 823, 903, 944.
Germany, restricting the number of physicians in, 983.
Germs, infravisible, 137.
Getman, A. A., gouty phlebitis, 134.
Gibson, Axel E., life and its physical basis, 172.
Gibson, C. L., the surgical treatment of colitis, 415.
Gieschen, Albert H., some comparative examinations of breast milk and cow's milk, and the effect of the addition of alkalies and other antacids to cow's milk, 201.
Girls, hygiene of young, 666.
Glanders at West Point, 863; diagnostic value of cultures in, 1030.
Glaucoma, acute fulminating, 869.
Glottis, œdema of the, 186.
Glycerin, antiseptic properties of, 981.
Glycosuria in the children of diabetic parents, 708; relation of, to diabetes, 17.
Goelet, Augustin H., how may we cure posterior displacement of the uterus? 11.
Goiter, distilled water in the treatment of, 381; partial thyroidectomy for, 871.
Goltman, M., poisoning with a small dose of quinine, 295.
Gonococcus infection of the entire upper extremity, 521; in infants, 761.
Gonorrhœa in women, 827, 987; treatment of, 896.
Gout, extensive development of tophi in, 32; in the United States, 300; modern views on, 457; phlebitis in, 134; some points in the diagnosis of, 216; treatment of, 130; vegetable diet in, 624.
Grabin, Charles S., abdominal pain in pneumonia, 776.
Granuloma of the nose caused by potassium iodide, 735.
Greenwich, Conn., hospital for contagious diseases at, 662.
Growth, effect of lecithin upon, 616; of children, arrangement of the clothing in relation to, 279; a case of abscess of the right cerebellar hemisphere with caries of the left mastoid process, 549.
Gruening, E., abscess of the left temporosphenoidal lobe of otitic origin; operation, recovery, 374.
Gumma of the liver in a child, 351.
Guthrie, J. A., investigation of rinderpest, 730.
Gynecological operations, causes of failure of relief from minor, 149; surgery, conservative, 746.
Gynecology, conservative, 433.

H

Hæmatocele, treatment of, 468.
Hæmoglobinuria, 426.
Hæmolysis in experimental infections, 187.
Hæmophilia, overian tissue in, 600.
Hæmospermia, 733.
Hæmostasis, electrothermic, 600.
Haig, Alexander, some notes on a diet of bread and fruit, and its effects on high blood-pressure, dropsy, and obesity, 690.
Hallux rigidus, hallux flexus, and hallux extensus, 706: valgus, 694; valgus, surgical treatment of, 391.
Hamilton, Allan McLane, traumatic locomotor ataxia, 801.
Hand-grapple for bed-ridden patients, 874.
Handkerchief, disease disseminated by the, 859.
Harben lectures before the Royal Institute of Public Health in London, 904.
Haslow, William B., circumcision in infancy, 496.
Harriman University, 101
Harvard Medical School, new buildings of the, 904.
Harveian oration, 783.
Hasbrouck, Sayer, a new form of insufflator, 839.
Havana, yellow-fever regulations at, 102.
Haven, Alfred C., a study of a scarlet-fever epidemic, 292.
Hay fever, 228, 229, 266; cause of, 179, 187; salivary and nasal secretions in, 553; serum treatment of, 148, 869; treatment of, 30.
Haynie, X. B., the advertising of operations in the daily press, 65.
Headache, diagnosis and treatment of, 817; ocular, 909; relation of neuraligic, to storms, 28; renal lowering of arterial tension in, 136.
Health Board, sale of antitoxin by the, to be restricted, 22.
Heart, arrhythmia of the, and indicanuria, 539; auscultation in the region of the, 976; bimanual massage of the, 787; effect of alcohol on the size of the, 749; estimation of pressure in the right auricle, 990; exercise in the treatment of diseases of the, 828, 831; influence of altitude upon disease of the, 266, 393; is disease of the, the cause or effect of the athletic habit, 867; mobility of the, 950; opium in disease of the, in children, 496; prevention of disease of the, 752; resuscitation of the action of the, after removal from the body, 428; significance of increase of erythrocytes in congenital effection of the, 707; signs of pulmonary stenosis, unexplained by the autopsical findings, 588; sub-diaphragmatic massage of the, 831; syphilitic affections of the, 321, 395; treatment of diseases of the, 869; value of drugs in weakness of the, 508.
Heat, exhaustion, 107; aphasia from, 416.
Hemiplegia, chronic progressive, 116; movement of superior intercostal muscles in, 877.
Hemorrhage, non-tuberculous, of the air-passages, 987.
Hemorrhagic diseases, allies of, 836.
Hemorrhoids, adrenalin in, 188; massage in the treatment of, 188; treatment of external, 511.
Hepatectomy for the removal of Riedel's lobe, 227.
Hepatic artery, ligation of the, for aneurysm, 830; fever, 347.
Heredity, alcoholism in relation to, 459; influence of, on the eye, 205.
Herpes gestationis, 429; zoster, motor troubles following, 574.
Hernia, 988; operative treatment of umbilical, 622; strangulated, in an infant of eleven days, 295; uterus and adnexa in the sac of a 391.

Heroin, anaphrodisiac action of, 989.
Herpes, tonsurans contracted from animals, 935.
Herrick, William Post, prostatic hypertrophy and its radical cure-243.
Hiccough, treatment of, 149.
Hickman, disappearance of Miss, 824.
Hibbs, Russell A., two cases of congenital elevation of the shoulder, with a review of reported cases, 168.
High-frequency currents, 681, 718; therapeutic uses of, 592, 753.
Higley. Henry A., differential leucocyte count in the early days of typhoid fever, 441.
Hip, congenital dislocation of the, 276; correction of deformity of the, following disease, 276; treatment of congenital dislocation of the, 426, 428.
Hip-disease, good results of the treatment of, 113; operative treatment of, 391; treatment of, 274.
Hog cholera, form of, not caused by hog cholera bacillus, 778.
Holden, Ward A., a case of paraffin injection into the nose followed immediately by blindness from embolism of the central artery of the retina, 53.
Homicide, what constitutes, 463.
Hospital, malpraxis suit against a, 180.
Hospitals, diseases of house officers in, 907.
Hot Springs, reformation of, 782.
Hot-water bottle, dangers of, as applied to the new-born, 214.
Humerus, gunshot injury of the, 391; traumatic separation of the lower epiphysis of the, 772.
Hungary, practice of massage in, 136.
Hunt, J. Ramsay, tumors of the fronto-medullo-cerebellar space, acoustic neuromata (central neurofibromatosis), 1001.
Hurd, Lee Maidment, a case of paraffin injection into the nose followed immediately by blindness from embolism of the central artery of the retina, 53.
Huxley, memorial lecture, 783.
Hyaline bodies in tumor, 788.
Hydrophobia, spurious, 187.
Hydrotherapy in pediatrics, 461; in the treatment of chronic disease, 331; some practical methods of, 198.
Hyoscine, poisoning by, 988.
Hyperchlorhydria, chemical diagnosis of, 268.
Hyperidrosis universalis, 910.
Hypernephroma, 947.
Hysteria, 988; before the age of two years, 625.
Hystero-salpingo-oophorectomy, 232.

I

Iboga, therapeutic action of, 951.
Idiocy, case of Mongolian, 235.
Ileocæcal valve, surgery of the, for cancer, 716.
Ileocotitis in children, 713.
Iliac, adenitis, 874.
Illinois, registration of births and deaths in, 21; State Board of Health, report of the, 62.
Immigration, public health aspects of, 792.
Immunity, Ehrlich's side-chain theory of, 787; fermentation theory of, 911.
India, etiology of one of the fevers of, 949.
Inebriate women, 380.
Infant feeding, 350; feeding, biological aspect of, 940; feeding, every-day problems in, 311; mortality, causes and prevention of, 792; mortality in nurseries and asylums, 638.
Infants, overlaying of, 938.
Infantile paralysis, 754; nature and treatment of, 753.
Infection, fermentation theory of, 911; hæmolysis in experimental, 187; upper respiratory tract a source of systemic, 536.
Infectious diseases of unknown etiology, 345.
Infective and infectious diseases, 191.
Influenza, appendicitis in relation to, 748; cardiac complications of, 667; in children, 66, 351; in New York State, 263; orchitis in, 228; symbiosis of the bacillus of, 147.
Infravisible world, 137.
Insane, camp life for the, 616; male, female nursing of the, 303; the convict, 1018.
Insanitary city, imperial rebuke to, 421.
Insanity as a sequel to physical conditions, 623; distribution of, 1019; increase of, in Great Britain, 263, 460; increase of, in New England, 101; puerperal, 427; question of, 901; relation of heredity to, 439; tuberculous, 540.
Insufflator, a chief and serviceable, 1000; new form of, 839.
International Congress of Hygiene and Demography, 502.
Intestinal anastomosis, 357; anastomosis, some recent methods of, 41; atony, physostigmine in, 625; crises 113; disorders, prolonged fasting in, 350; fermentation, surgical aspects of, 1011; fermentation, indol in the fæces as an indication of, 1024; infarction, 870; lithiasis, 626; obstruction, absolute constipation in, 136; obstruction, acute, 588; obstruction by ascarides, 69; obstruction, non-surgical treatment of acute, 185; obstruction resulting from a kick in the right iliac region, 346; obstruction, tardy postoperative, 546; obstruction, unusual case of, 909; parasites, clinical diagnosis of, 145; parasites, statistical study of, 222.
Intestine, antiseptic lavage of the, 669; cancer of the, in youth, 626; exogenous perforative ulceration of the, 16; innervation of the large, 589; massage of the, 749; mechanism of strangulation of the, 30, 788; neuroses of the, 753; traumatic rupture of the, 626.
Intoxicant, a new, 617.
Intubation tubes, prolonged retention of, 354.
Intussusception, diagnosis and treatment of, 965; of the ileum, spontaneous recovery from, 306.
Iodide of iron, uses of the syrup of, 838.
Iodine reaction in children, 786.
Iritis, diagnosis of, from conjunctivitis, 856.
Irritations, vital action of, 429.
Itching as a cause and concomitant of disease, 978.
Ivory bone grafting, 669.

J

Jail system, evils of the county, 100.
Japanese, stature of the, 380.
Jaundice, diagnosis of the causes of, 68; significance of, in disease of the biliary tract, 305; Widal reaction in, 389, 916.
Jaw, sarcoma of the lower, 947.
Jenner Institute of Preventive Medicine, change of name of, 342.
Jervey, J. Wilkinson, the treatment of lacrymal stricture, 998.
Jibes at the doctors, ancient, 408.
Joint diseases, missing links in, 211; mice, observations on, 936.
Joints, treatment of traumatic affections of the, 789.
Jones, Mary A. Dixon, fibrocystic tumors of the uterus: their etiology, 561.
*Journal of the Royal Army Medical Corps*, 180.
Jugular bulb, thrombosis of the, 556; vein, removal of the internal, 186.
Jungle, victims of the, 925.

K

Kakels, M. S., a preliminary report on some experiments with the McGraw elastic ligature, 294.
Kane, C. J., modifications of Brewer's speculum and Boldt's scissors, 238.
Keate, Walter, extensive brain loss without impairment of the intellectual faculties, 613.
Keefe, John W., ligature and suture carrier, 158.
Kempf, E. J., a cheap and serviceable insufflator, 1000.
Keratitis, subconjunctival injections of tuberculin t. r. in interstitial, 589.
Keratoses, precancerous, 517.
Kerley, Charles Gilmore, some comparative examinations of breast milk and cow's milk, and the effect of the addition of alkalies and other antacids to cow's milk, 201.
Kerrison, Philip D., the prognosis and treatment of chronic deafness, 810.
Kidney, decapsulation of the, 304; decapsulation of the, in the treatment of chronic Bright's disease, 474, 629; effect of catheter drainage on the functions of the, in nephritis, 868; fat necrosis of the, 66; functional activity of, in relation to operations, 147; movable horseshoe, nephropexy for, 231; movable, with secondary cyst formation, 715; nature and etiology of granular, 830; nephrectomy for cancer of the, 429; new method of fixation of movable, 96; polycystic, 231; protoplasmic activity of the epithelium of the, 868; saline enemata after operations on the, 500; subparietal injuries of the, 145, 476; surgical, 231, 232; suturing a prolapsed, 797; syphilitic tumors of the, 870; treatment of calculus of the, 69; treatment of infective wounds of the, 951; treatment of movable, 949; treatment of prolapse of the, 799; tumors of the, 31; unusual results of movable, 631.
Kimball, Reuel B., gonorrhœa in infants, with a report of eight cases of pyæmia, 761.
Kinnicutt, Francis P., eye-lesions in heart and kidney disease, 884, 913.
Knapp, Mark I., some of the mistakes we have inherited, 450.
Knee, early operative, treatment of tuberculosis of the, 274; excision of, for ankylosis, 273; formation of loose cartilages in the, 666; infections of the, 988; treatment of acute suppuration in the, 508.
Knight, Frederick I., the early diagnosis and treatment of tuberculosis, 621.
Knock-knee, surgical pathology of, 273.

Knopf, S. A., American and international congresses on tuberculosis and tuberculosis exhibits for the years 1904 and 1905, 906.
Koch, criticism of, for studies of cattle disease, 618; sixtieth birthday of, 1021.

Koplik's spots, significance of, in measles, 228.
Korsakoff's disease, a study of, 104, 177.
Körte-Ballance operation, 623.
Kucher, Joseph, some practical remarks on the management of breech presentations, 55.

L

Labor, indications for the induction of, in hyperæmesis and cardiopathy, 510.
Lacrymal stricture, treatment of, 998.
Lactation, poisoning of infant from maternal causes during, 377.
Laparotomy, convalescence from, 336; secondary or repeated, 233; thrombosis of the femoral veins following, 432, 613.
Lapponi, Giuseppi, honors for, 421.
Laryngeal stidor, congenital, 127; tuberculosis, treatment of, by galvanopuncture, 110.
Larynx, cancer of the, 788; perichondritis of the, 130, 154; postdiphtheritic stenosis of the, as a cause for persistent intubation, 161, 236; skin-grafting in stenosis of the, 622; treatment of papilloma of the, in children, 345; tuberculous stenosis of the, treated by tracheotomy, 553.
Lateral curvature of the spine, 279; treatment of, 1008.
Laundresses, phthisis in, 268.
Lead, osteoperiostitis due to the action of 776; poisoning, renal and gastric lesions in, 110.
Lecithin, 871; effect of, upon growth, 616.
Lepers in Northern Nigeria, 580.
Leprosy, early diagnosis of, 516; fish theory of the spread of, 316; history of, 98; in Hawaii, 787, 961; quarantine regulations for, 160; Roman Catholicism in relation to, 60; sanitary aspect of, 787; Zambaco Pasha's views on, 424.
Leucocyte count in gynecology, 256; in cases resembling appendicitis, 631.
Leucocytes, neutrophilic granulations of the, 389.
Leucocytosis, diagnostic value of, 30.
Leukæmia, acute myelogenic, 470; etiology of, 146; myelogenous, 953; splenomedullary, treated by the *x*-rays, 281.
Lichen pilaris, treatment of, 111; ruber planus of the mouth, 1027.
Life, basis of, 172, 344, 379; principles of, 253.
Life insurance, diseases of the ear in relation to, 558; impaired risks in, 347; phthisis in relation to, 936.
Ligaments, shortening the, by the blunt-hook method, 672.
Ligature and suture carrier, 158.
Light, biological action of blue, on muscular labor, 510.
Lime "adsorption" by animal tissues with respect to a modern theory of rickets, 589.
Lingual artery, anomalies of the, 831.
Linseed poisoning, 909.
Lipæmia, diabetic, 668, 735.
Lithiasis, treatment of renal, 69.
Lithotomy, suprapubic, 851.
Liver, atrophy of the large cirrhotic, in infections, 626; cirrhosis of the, in a child, 995; cryoscopy of the urine and ascitic fluid in, 16; drainage of the, 632; dysenteric abscess of the, 389; experimental intrahepatic infections, 469; resection of the, 818; rôle of the, in the cause, prevention, and treatment of disease. 56; simple cysts of the, 866; some common forms of disturbance of the, 908; surgical interference in hypertrophic biliary cirrhosis of the, 721; syphilis of the, from a surgical standpoint, 70; Talma's operation in cirrhosis of the, 746; treatment of abscess of the, 706; tropical abscess of the, 316, 856.
Locomotor ataxia, traumatic, 801.
Loewenstein, H. Correll, two cases of congenital elevation of the shoulder, with a review of the reported cases, 168.
London, letters from, 23, 64, 104, 143, 182, 225, 264, 303, 343, 384, 423, 464, 504, 543, 584, 610, 664, 703, 744, 783, 826, 866, 904, 945, 986, 1023; post-graduate study in, 560; medical charity, abuse in, 419; statistics of, 698.
Longevity, increased, 960.
Lumbar puncture, value of, in general practice, 147.
Lungs, cancer of the, 628; ichthyol in diseases of the, 813; supraclavicular hernia of the, 114; surgery of gangrene of the, 757.
Lupus erythematosus, light in the treatment of, 56; vulgaris, potassium permanganate in, 68; vulgaris, treatment of, 869; vulgaris, *x*-ray treatment of, 126.
Lymphatism, two cases of, 336.
Lymphocytes, movement and migration of the, 176.
Lymphœdema of the skin due to suppuration of superficial lymphatic glands, 589.

M

MacAdam, Henry Graham, purpura hæmorrhagica fulminans, 290.
McCaskey, G. W., a case of combined pyloric cancer and phlegmonous gastritis, 576.
McGraw, elastic ligature, 294, 465.
Madeira Islands, sanatorium monopoly in the, 63.
Malaria, complications and sequelæ of, 829; extirpation of, in the Soudan, 343; hepatic insufficiency in, 468; hybrid, 135; in temperate climates, 265; mosquitos in relation to, 196, 229; outbreak of, on shipboard, 28; pathology of latent infection of, 186; prevention of, on shipboard, 440; prophylaxis of, 110; rare cerebral complication in, 928; sodium salicylate in, 146; soil nitrification as a preventive of, 19; symposium on, 35; tremor and hemiparesis following, 30.
Malta fever, case of, in Washington, 612; duration of, 870.
Manic depressive psychosis, 823.
Manila, a health lesson in, 542; letters from, 24, 105, 183, 385, 425, 505; sanitary condition of, 97; work of the sanitary authorities in, 505.
Manley, Thomas H., the range of osteoplasty as an aid in the conservative surgery of bone traumatism, 448.
Marching, leg and foot in relation to, 979.
Marshall, E. G., electricity in the treatment of diseases of the stomach, 209.
Massage by the blind, 960, 990.
Masticate, the instinct to, 340.
Mastoid antrum, depth of the, 127; disease, extradural abscess in, 675; unusual cases of disease of the, 556.
Matter, newer conceptions of, 18.
Mayer, Emil, perichondritis of the larynx, with report of a case, 130, 154.
Measles, antenatal, 788; coma in, 986; eczema cured by, 613; guaiacal carbonate in, 909.
Medical education in the United States trend of, 258; education standards of, 194; profession in Great Britain, prospects of the, 217; profession, past and present needs of the, 678; science, economic value of, 913.
Medical Society of New Jersey, 193.
Medical Society of the County of New York, 113, 718, 798, 958.
Medical Society of the State of New York, 632.
Medical Society of the State of North Carolina, 63.
Medical Society of the State of Pennsylvania, 596, 628.
Meeker, Irving A., nitrous oxide in the production of surgical anæsthesia, 490.
Melanoma, 4.
Membrana tympani, exploratory puncture of the, 557.
Ménière's disease, present status of, 298; treatment of, 976.
Meningitis, flaccid paralysis following cerebrospinal, 117; otitic serous, 633; the nerve cell in, 307; tuberculous, in an adult, 29.
Menstruation, early, 939.
Mental defect and shock, 878; disease, action of blood serum on B. coli communis in cases of, 624; disease, early diagnosis of, 752; disease, early treatment of, 753; diseases, expert testimony regarding, 199; diseases, facial irritability in, 114; therapeutics, principles underlying, 118.
Mercury salicylate, fatal poisoning by, 820; simple method of administering, 111.
Mesentery, defensive functions of the greater, 268.
Methyl alcohol in extracts and medicine, 460.
Meyer, Willy, prostatectomy and galvanocaustic prostatotomy (Bottini's operation), their present status in the radical treatment of the hypertrophied prostate gland, 641.
Microscope lenses, deterioration of, in the tropics, 319.
Midwives, legislation regarding, in Great Britain, 193.
Migraine, 69; gastric phenomena accompanying, 830; gastrointestinal disturbance with, 829; treatment of, 587.
Military sanitation, responsibility for, 337.
Milk commission of the Medical Society of the County of New York, work of the, 21, 799; comparative examination of woman's and cow's, 201.

Milk, constituents of a quart of, 951; dirty cans for, 822; effect of addition of alkalies to, 201; formaldehyde in, 421.
Milk, function of maternal, in developing the stomach, 921, 953; in infant feeding, 989, 992.
Milk, pure and impure, in infant feeding, 948; relation of municipal supply of, to the health of children, 673; transmission of bovine tuberculosis by, 737.
Miller, Charles C., perineal section for stricture, with suggestions upon the use of the cautery, and points in the after-treatment, 854.
Miller, James Alexander, the management of cases of pulmonary tuberculosis in the dispensary, 282.
Miners' phthisis, 460, 509.
Minus cylinders, 680.
Mississippi Valley Medical Association, 751.
Mistakes we have inherited, 450.
Mitral stenosis with multiple emboli, 915.
Moffat, Henry, a report of three years of operative work per vaginam at St. Joseph's Hospital, Yonkers, N. Y., 886, 915.
Molluscum fibrosum of rectum in a patient with the typical skin lesion, 869.
Morphinism, successful treatment of. 345.
Morris, Robert T., a cirrhosis brush, 120; intestinal fermentation as it interests the surgeon, 1011.
Morton, William James, some cases treated by the *x*-ray, 121; artificial fluorescence of living human tissue, 215.
Moser, W., a case of lead osteoperiostitis, 776.
Mosquito-bar, early observation on the prophylactic value of, 341.
Mosquito-plant, 223, 421.
Mosquitos, a parasitic worm in, 103; efforts to abate the nuisance, 226, 943; destruction of, 656, 789; habits of the yellow fever, 301; length of life of, 520; malaria in relation to, 196; plague of, 103; possibility of ridding a district of, 461, 464; ship-bred, 501; the yellow fever, protozoan parasite in, 257.
Mouth-breathing, r tional treatment of, 375.
Munich, coeducation at, 903, 985.
Muscle, capacity of the, for work, 1025; tonus, 929.
Muscular dystrophy, 178; pseudohypertrophy, 877.
Mutter lecture before the College of Physicians of Philadelphia, 943.
Myers, George T., some comparative examinations of breast milk and cow's milk, and the effect of the addition of alkalies and other antacids to cow's milk, 201.
Myoma, sarcomatous transformation of, 705.
Myopia, causes, prevention, and management of, 908.
Myositis ossificans traumatica, 549; post-typhoidal, 907.
Myotoxic serum, 111.
Myxœdema, anomalous case of, 993.

N

Narcosis, morphine-scopolamine, 950; stomach tube for use during, 429.
Nasopharynx, sarcoma of the, 154,
Nassau, climate of, 392.
Naval hospital at Portsmouth, 463.
Navy, status of the surgeon in the, 696.
Naz rene nurses, 502.
Neftel, W. B., electricity in general practice, 841.
Neoplasms, prevention of, by physicotherapy, 167.
Nephrectomy, experimental study of, 268.
Nephritis, chronic interstitial, 754; chronic, without albuminuria, 508; dangers of exclusive milk diet in, 119; danger of sodium chloride in, 189; diet and drugs in, 08; dietetic treatment of chronic, 597, 747; hygiene and dietetic treatment of chronic, 736; interstitial and pyelo-, effect of catheter drainage on the functions of the kidneys in, 477; reflexes in, 816; surgical treatment of chronic parenchymatous, 695; syphilitic, in an infant, 509; treatment of acute, 899; treatment of, by reduction of chlorides, 188; without casts in the urine, 509.
Nephroptosis, cause of failure of operation for, 674.
Nerve-cell, development of neurofibrils in the, 119.
Nervous diseases, facial irritability in, 114; diseases, relation of autointoxication to, 416; system, primary sarcomatosis of the, 77; system, strychnine in degenerative diseases of the, 387.
Neuralgia, altitude in relation to, 394; brachial, 147; facial, due to nasal and antral disease, 155; neurasthenic, 118; osmic acid in trigeminal, 344; treatment of brachial, 306.
Neurasthenia, 61; diet in, 479.
Neuritis, alcoholic multiple, 1030. peripheral, 1025; peripheral of the alcoholic type, 494.
Neurofibroma of skin and large nerve trunks with spindle-celled sarcoma beneath the scapula, 690.
Neurofibromatosis, central, 116.
Neuroma, stump, 874.
Neuroses, radiant-light treatment of, 594.
New-born, nephritis of the, 469.
Newcomb, James E., congenital laryngeal stridor, 127.
Newell, Frank P., a typical case of sporadic cretinism, 896.
Newfoundland fishermen, medical care of the, 300.
New Jersey, educational medical standards in, 821; medical practice requirements in, 861.
New Jersey State Dental Society, 141.
New Orleans, beginning of work on a sewerage system for, 22.

Permanganate of potassium in lupus, 68.
Pessary, use of the stem, for infantile uterus, scanty menstruation, amenorrhœa and dysmenorrhœa, 715.
Phagedona, treatment of the congeners of, with turpentine, 936.
Pharyngitis, treatment of chronic, 800.
Pharynx, syphilitic abscess of the, with necrosis of a cervical vertebra, 550; tuberculosis of the, in children, 748.
Philadelphia County Medical Society, 701, 824, 902.
Philadelphia Neurological Society, 743, 902.
Philadelphia Pediatric Society, 663.
Philadelphia Society of Trophical Medicine, 582.
Philippines, quarantine work in the, 859.
Phlebitis, gouty, 134.
Phlegmasia alba dolen, treatment of, 305.
Phonation phenomena, the intercostal, 212.
Phototherapy, 648; in cancer, lupus, and other conditions, 736; present status of, 517.
Phthisis, certain bodily conditions resisting, 56; treatment of, 69.
Piano playing, neurosis from, 575.
Piffard, Henry G., high-frequency currents, 681, 718.
Pin, swallowing of a, without bad results, 267.
Pityriasis rosacea, 67.
Placenta prævia, bloodless, 296.
Plague among domestic animals, 184; an international congress on the, 617; bacteriology of, 195; carbolic acid in, 695; carbolic acid in the treatment of, 509; case of laboratory, in Berlin, 183; etiology of, 706; fleas as carriers of, 141; immunization against, by nonvirulent cultures, 228; in Berlin, 183; in domestic animals, 318, 740; in Hongkong, 183; in Marseilles, 463; in Peru and Chile, 466, 704; in San Francisco, 224; in Sydney, 980; measures for the suppression of the, in Manila, 184.
Pleural effusions, treatment of, 187.
Pleurisy, eosinophilia in, 307; recovery from grave purulent, 468; serofibrinous, cytological diagnosis of, 216; treatment of, 831.
Pneumobacillus, general infection with the, 267.
Pneumonia, abdominal disease associated with, 829; abdominal pain in, 776; and tuberculosis, relative importance of, to the community, 989; complications of, 398; creosote in the treatment of, 559; croupous, in infancy, 187, 996; death rate of, 227, 398; epidemic, 707; in infancy, 68; management of catarrhal, in infants, 352; pathology and treatment of, 250; pilocarpine in, 540; seasonal prevalence of, 398; simulating appendicitis, 197; traumatic, 185; treatment of, 398, 679; turpentine treatment of, 68.
Pneumothorax associated with fracture of the ribs, 746; in children, 1000.
Poisoned wounds in warfare, 738.
Poisoning by corrosives, 28.
Poisons, secret, and their use in ancient times, 286.

Polar regions, microbes in the, 40.
Polycythæmia, chronic cyanotic, 28, 807.
Polypi, etiology of nasal, 911; nasal, prevention of the recurrence of, 829.
Polyuria, strychnine in, 347.
Pooley, Thomas R., a case of leucosarcoma of the choroid, 447.
Pope Leo, cause of the death of, 462; report of the autopsy on, 181.
Portal anastomosis, the anatomy of, 4.
Pottenger, F. M., the need of organized effort in the prevention of the spread of tuberculosis, 610.
Powers, Charles A., a case of diffuse gonococcus infection of the entire upper extremity, 521.
Practitioners' Society of New York, 32, 514, 917.
Precipitins formed by injecting animals with globulin of normal and diphtheritic antitoxic horse serum, 1032.
Pregnancy, biochemistry of, 468; combined ectopic and intrauterine 717; complicated with fibroids, 355, 954; early diagnosis of, 67; extrauterine, 717, 755, 837, 956; extrauterine, early diagnosis of, 347; extrauterine, internal hemorrhage in association with, 356; influence of diet during, on the weight of the offspring, 109; interruption of, in cardiac and other diseases, 990; significance of albuminaria in, 957; toxæmia of, 956; tubal, 706; vomiting of, 957.
Preventive medicine and natural selection, 940.
Price, A. F., copper in syphilis, 572.
Prisons in New York, condemnation of the, 983.
Privileged medical communications, 498, 515.
Prize, Alvarenga, 742; award of the Stewart, 191; Craig Colony, 742; Dr. Spencer Morris, 463; Enno Sander, 700; graduate, of the Medico-Chirurgical College, 141; of the American Medical Association, 462; offered for method curative of horse sickness in the Transvaal, 520; the Senn, 903; Warren triennial, 823.
Proctocolitis, treatment of, 598.
Prostate, albuminuria following massage of the, 30; cancer of the, 109, 438, 706; choice of technique in operations on the, 266; cystoscope in the study of hypertrophy of the, 474; infection of the, 433; needle in the, 775; radical cure of hypertrophy of the, 243; surgery of the, 304.
Prostatectomy, 359; and galvanocaustic prostatotomy, 641; conservative perineal, 435; indications and technique of, 756; perineal, proper incision for, 305; perineal, without opening urethra or bladder, 427; report of twenty-five cases of, 710.
Prostatics about to enter catheter life, suggestions to, 438.
Pruritus, treatment of, 347.
Pseudohydronephrosis, 354.
Pseudoleukæmia, infective splenic, in children, 625.
Psoriasis, *x*-ray treatment of, 126.
Psychiatry and the side-chain theory, 989.
Psychology, problem in medicolegal, 346.
Psychoses, pathogenesis of acute, 307.
Psychosis, manic depressive, 526.
Ptosis, operation for, 589.
Puerperal eclampsia, epilepsy and nephritis simulating, 868; eclampsia, veratrum viride in, 65; fever, ichthyol in, 414; fever, prophylaxis and therapy of, 429; infection, chloride of lime in, 911; insanity, 427; sepsis, hospital methods of prevention and treatment of, applied to private practice, 28; sepsis, operative treatment of, 111; sepsis, peritoneal irrigation with saline solution in, 140; sepsis, symposium on, 155; sepsis, treatment of, 677; septicæmia, antistreptococcus serum in, 829; septicæmia, treated by antistreptococcus serum, 588.
Pulmonary osteoarthropathy, 708.
Pulmonary tuberculosis, camphorated oil in, 936; dietetic and drug treatment of, 668; dispensary treatment of, 282; early diagnosis of, 916; formaldehyde in, 318; ichthyol in, 306; iodoform in, 909; lime-dust inhalation in relation to, 910; practical treatment of, 596; respiratory insufficiency in, 70; surgical treatment of, 749; sweating in, 789; temperature in, 318.
Pulsation, bigeminal, 830.
Pupil, size of the, as an aid to diagnosis, 391.
Purgatives, modus operandi of saline, 222.
Purpura hæmorrhagica, adrenalin in, 669; hæmorrhagica fulminans, 290; Henoch's, 995; malarial, 518.
Pyæmia, gonorrhœal, in infants, 761.
Pyelitis as a cause of intermittent pyrexia in children, 407.
Pyloric stenosis in infants, 235.
Pylorus, chronic hypertrophic stenosis of the, 705.
Pyosalpinx, removal of uterus and ovaries in operation for double, 671.
Pyothorax, costal and thoracic resection for, 994.
Pyrexia, some less usual causes of postoperative, 676.

Q

Quacks, prosecution of, 799.
Quadriceps extensor femoris, rupture of the, 828.
Quadriceps-operation, plastic, 669.
Quarantine, early history of, 178.
Quick and the dead, a plea for urn burial, 327.
Quinine, fatal poisoning by, 822; poisoning with a small dose of, 295.

R

Rachitis deformities, mechanical *vs.* operative treatment of, 273.
Rabies, action of quinine on the virus of, 469; in London, 496; Negri's organism of, 669; prevention of, 305.
Radiography, an improvement in, 388.
Radiotherapy, 827.
Radium, 520, 635; bactericidal action of the rays of, 220; cancer treated by, 63, 601; discovery of, 836; lessons of, 320; manufacture of, 983; medical uses of, 142; properties of, 29; therapeutic use of, 660, 676; uses of, in surgery, 440.
Railway injuries, damages for, 462.
Rats, crusade against, 984.
Raue, C. Sigmund, an instrument for the rapid estimation of the acidity of the gastric contents, 438.
Raynaud's disease, a case of, 517.
Reciprocity, medical, 99.
Rectoscopy, technique of, 1027.
Rectum, congenital absence of the, 576; foreign bodies in the, 855; operation for prolapsed, 386; operative treatment of cancer of the, 674.
Red Cross, appeal for the, in Turkey, 583.
Reed, Major Walter, memorial to the late, 341.
Reflex, the Achilles-tendon, 77.
Reflexes, study of, 629.
Refuse materials, disposal of, 793.
Registration, medical, in Canada, 621.
Respiratory and pelvic diseases, relations between, 466.
Respiratory tract, acquired cicatricial deformities in the, 152; cicatricial deformities in the, 771; the upper, 631.
Restaurants, insanitary kitchens in, 900.
Retina, new operation for detached, 30; pigmentary degeneration of the, 266; treatment of atrophic, with retinal extract, 228.
Retinitis, albuminuric, 987; atrophic, use of retinal extract in, 589.
Retropharyngeal abscess, 553.
Revenue cutter, duties of a surgeon on a, 541.
Rheumatism, apparent infection of, 306; antistreptococcus serum in, 668; epistaxis at the onset of, 991, in childhood, 296; in children, typhoid fever resembling, 266; non-articular tuberculous, 469; pathology of acute, 588; passing of chronic, 387; *vs.* muscular and joint pains, 469.
Rheumatoid arthritis, blood in, 467; pathology and treatment of, 508.
Rhinitis, autochthonous atrophic, 536; effect of erysipelas upon atrophic, 387.
Rhinological practice, principles of, 240.
Rickets, etiology of, 836.
Rinderpest in the Philippines, 425; investigation of, 730.
Risks, impaired, 347.
Robinson, Beverley, some aspects of the old and the new; a plea for conservatism in medicine and surgery, 481, 514.
Robinson, Byron, peritonitis (peritoneal adhesions) caused by muscular trauma, 324.
Rodent ulcer, *x*-rays in the treatment of, 336.
Rogers, Albert E., treatment of cervical adenitis due to tonsillar infection, 853.
Röntgen rays, cure of splenomedullary leukæmia with the, 281; dermatitis due to, 1000; effect of, upon eyesight, 594; in cancer, 66, 150, 948; in dermatology, 514; in rodent ulcer, 336; in tuberculosis, 948; injuries caused by, 302; plea for accurate and scientific methods of treatment with, 596; previously unrecognized action of, on the animal organism, 830; protection against, 1027; some cases treated by the, 121; therapeutic applications of, 591, 593, 595, 598, 634.
Rosenberg, Maurice, foreign bodies in the rectum, with report of two cases, 855; internal administration of ichthyol in pulmonary affections, 813.
Rosenstein, Julius, surgical interference in hypertrophic biliary cirrhosis of the liver, 721.
Rossiter, Frederick M., hydrotherapy in the treatment of chronic disease, 331.
Roth, Henry, diagnosis and treatment of intussusception, 965.
Rubber, preservation of, 511.

Runners, the reflexes in long-distance, 77.
Rush Medical College in the University of Chicago, 141.

S

Safranin reaction of the urine in children, 353.
Sahli test-meal, observations on the use of, 893.
St. Luke's Day service for physicians, 662.
Saline infusion, physiological action, indications, and technique of, 297.
Saliva, chemical pathology of the, 150.
Salpingitis, etiology, pathology, and treatment of, 712; treatment of, 631.
Sanatoria for consumptives, 900.
Sanatorium, King Edward's, 866.
Sanitary Congress, British, 225.
Sarcoma cured by Coley's fluid, 583; multiple periosteal, of the cranium, 546; small spindle-celled, of the ovary and liver, 232; x-ray treatment of, 634.
Sarcomatosis cutis, 479.
Scaphoid bone, dislocation of the carpal, 189.
Scarlet fever, 622; a malignant epidemic of, 69; and diphtheria, borderland of, 937; late contagion of, 189; latent, 669; peritonitis in, 987; possibly due to a protozoan parasite, 1019; serum treatment of, 63; study of an epidemic of, 292; treatment of, 353; vitality of bacteria from the throats of sufferers from, 60.
School hygiene, 675; in England, 584; international congress of, 582.
Schools, daily medical inspection of public, 943; physical education in the public, 988.
Schroeder, Henry H., the clinical importance of albuminuria, 88.
Schroeder, J. Henry, two new methods of determining the digestive activity of gastric juice, 685.
Sciatica, 388; hydriatic treatment of, 95; treatment of, 706.
Science, victories of modern, 339.
Sclerosis, insular, diagnosis of Friedreich's disease from, 629.
Scoliatone, the, 279.
Scott, G. S., gonorrhœa in women, 827.
Scorbutus, infantile, 467.
Scrotum, avulsion of the, 434.
Sea air and sea bathing, effect of, on nutrition, 268; bathing, 673.
Seasickness, 911; painful points in, 465.
Secret, medical, 498, 515.
Senn, Nicholas, case of splenomedullary leukæmia successfully treated by the use of the Röntgen ray, 281.
Sepsis, treatment of acute, 296; treatment of peurpeal, 631.
Septicæmia, a case of, 306.
Septic infection, hot dry air in the treatment of, 108.
Septum nasi, bilateral abscess of the, with septicæmia, 554; submucous resection of the, 1013.
Serositis, 1031.
Serum-therapy, recent progress in, 137; rectal, 29.
Sewage disposal, 679.
Sewerage in tropical cities, 819.
Sexual hygiene, instruction in, 798.
Sheldon, John G., hallux valgus, 694.
Shellenburger, J. R., circumcision in infancy, 621.
Ships, care of invalids on, 100.
Shock, condition of the vasomotor neurons in, 705; surgical relation of the solar plexus to, 467; treatment of surgical, by adrenalin, 869.
Shoulder, congenital elevation of the, 168; irreducible dislocation of the, 70.
Shultz, R. C., is heart disease the cause or the effect of the athletic habit, 867.
Sialogogues, therapeutic employment of, 255.
Sigmoid flexure, adenocarcinoma of the, 837; cancer of the, 955
Sigmoiditis, acute, 1027.
Silicic acid, physiological action and pharmaco-dynamics of, 624.
Silver, removal of stains of, from white fabrics, 976; treatment of septic conditions by intravenous injections of soluble, 711.
Sinusitis, chronic maxillary, pathognomic sign of, 226; diagnosis and treatment of nasal, 109, 152; frontal, 556; nasal, 198.
Sitophobia and inanition, treatment of, 470.
Sitz-bath, therapeutic value of the cold, 469.
Skin, action of heat and light rays on the, 707; case of undetermined infection of the, 478; hysterical neuroses of the, 478; lesions of the, associated with rapid growth of long bones, 746; precancerous affections of the, 517.
Skull, case of extensive fracture of the, 200.
Slate pencils, disinfection of, 945.
Sleeping sickness, 780; etiology of, 16; geographical distribution of, 258; trypanosome in, 314.
Smallpox and varicella, 820; carbolic acid in, 747; etiology and pathology of, 857; fœtal, 146, 377; goat cure for, 616; life history of the organism of, 780; pathology of, 559; phototherapy in, 951; pustulation and its secondary fever a complication and not an essential symptom of, 227; red-light treatment of, 58, 307; revaccination in relation to, 109.
Snake venom, study of, 20.
Sneeze, diagnostic value of the, 519.
Soap tincture as a disinfectant of surgical instruments, 30
South Africa, British commission on the war in, 699.
Southern Medical College Association, 1022.
Spasm, essential or idiopathic, 587.
Sphygmograph, a mirror, 789 .
Spinal cord, removal of a tumor of the, 77; cord, x-ray in lesions of the, 592; rheumatism, 510.
Spine, double curvature of the, 109; lateral curvature of the, 279; therapeutic value of heat and cold applied to the, 752; treatment of lateral curvature of the, 1008.
Splanchnoptosis caused by omental adhesions, 468.
Spleen, nucleated red blood corpuscles in the, 909; surgical treatment of traumatic hemorrhage of the, 868.
Splenectomy, temperature course after, 830.
Splenomegaly, chronic cyanosis of the extremities associated with, 807.
Spondylitis deformans, 911.
Spooner, Henry G., inflammation of the bladder, 889; stricture of the male urethra, 606; the cystoscope, its indications and contraindications in genitourinary diseases, 51.
Spotted fever of the Rocky Mountains, 547, 898.
Sprains, medical gymnastics and massage in, 702.
Spratling, William P., the frequency wave of epileptic seizures, 656.
Sprue, tropical, 270.
Squires, G. W., eczema cured by measles, 613; congenital absence of the rectum with imperforate anus, 576.
Stacke's operation, 108.
Static currents in nervous diseases, 592; secondary, in albuminuria, 590.
Stamford, Conn., Hospital, gift to the, 945.
Stammering, treatment of, 27.
Starr, M. Allen, arterial sclerosis as a cause of nervous disease, 1, 33.
Status lymphaticus, 1017.
Stedman, Chester J., a possible case of infant poisoning as a result of abnormal mental and physical condition of the mother, 377.
Steers, William H., an operation for removing the tonsils, 535.
Stegomyia fasciata, characteristics of, affecting the conveyance of yellow fever, 794.
Stevens, George T., a new model of the clinoscope, 79.
Stewart, Douglas H., some dangers of the hot-water bottle as applied to the new-born, 214.
Still-birth due to strangulation of the funis, 623.
Stokes-Adams disease, 388, 668.
Stomach, cancer of the pylorus with symptoms of gastrocolic fistula, 623; cancer of the, with phlegmonous gastritis, 576; complications of cancer of the, 910; dangers and uses of inflation of the, with carbonic acid gas, 1025; diagnosis of ulcer of the, 950; diseases of the, 387; electricity in diseases of the, 209; function of maternal milk in developing the, 921, 953; green contents of the, 704, 785; hemorrhagic erosions of the, 748; hour-glass contraction of the, 391, 745; medical treatment of ulcer of the, 271; neuroses of the, 753; operation for perforated ulcer of the, 671, 744; perforating ulcer of the, 632; present status of surgery of the, 757; prophylaxis of cancer of the, 949; rapid estimation of the acidity of the contents of the, 438; Röntgen pictures of the movements of, 625; solitary tubercle of the, 735; surgical treatment of diseases of the, 831; treatment of chronic round ulcer of the, 546; ulcer of the, fallacy of physical signs in the diagnosis of, 909; volvulus of the, 747.
Stomach-tube, first use of, by an American, 580.
Stone, Willard J., postgraduate work in Budapest, 494.
Stoner, A. P., a case of venereal warts, 495; circumcision in infancy, 622.
Stony Wold Sanatorium, description of, 959; opening of, 342.
Storms, relation of neuralgic headaches to, 28.

Strabismus, treatment of, 511, 630, 667.
Strasser, August Adrian, a rare case of patent diverticulum ilei, 933.
Street accidents in New York and London, 823.
Street-car problem in New York, 862.
Streptococci, researches regarding, 147
Streptococcus, antisera of, 597.
Stricture, perineal section for urethral, use of the cautery in, 854.
Strike of club doctors in Germany, 382.
Strumitis, post-typhoid, 429.
Stubbert, J. Edward, tent life for consumptives, 13.
Sturmdorf, Arnold, observations on retraction and retractors in abdominal surgery, with demonstration of an automatic cœliotomy retractor, 37.
Styes, treatment of, 511.
Sugar, excretion of, in relation to fever, 589; nutritive value of, 760.
Suicide, increase of, 540; in the United States, 260; question of, 579.
Sulphurous acid, disinfectant value of, 57.
Surgeon operated upon by his father, 262; operated upon by his wife, 21.
Surgery, comparison of German and American, 480; evolution in, 190; gynecology and true, 233.
Surgical practice, suggestions in, 799.
Surra, study of, in Manila, 425.
Susceptibility and infection, 318.
Sutton, Richard Lightburn, the internal administration of methylene blue as an aid in the diagnosis of urethroperineal fistula, 376.
Swabs, sterilized, 456.
Swimming baths, bacteria in the water of public, 320.
Switzerland, medical students in, 519.
Sycosis, *x*-ray treatment of, 125.
Syphilis, bacillus of, 546; copper in, 572; ethical relations of, 698, 736; hepatic, from a surgical standpoint, 70; hypodermic use of mercury in, 752; late hereditary, 346; ocular manifestations of hereditary, 30; of the heart and aorta, 321, 395; of the nose and pharynx, 754; of the nose and throat, 631; preventive treatment of the primary lesion of, 950; repression of, 579; splenomegaly in, 149; terminal, and tabes, 766
Syphilitics, workhouses for, 669.
Syphilography, a new journal of, 383.

T

Tabes dorsalis, incipient, and cerebrospinal syphilis, 910; intense mercurial treatment of, 585; pupillary disorders in, 229; terminal syphilis in relation to, 766; traumatism in relation to, 188.
Tænia, chloroform in the treatment of, 148.
Talma's operation, indications and results of, 989.
Tank, septic, in the disposal of excreta, 269.
Tapeworm, treatment of, 828.
Tar as a covering for streets, 110.
Taylor, Henry Ling, injection of paraffin of high melting point, 304.
Teeth and gums, inspection of the, as an aid to diagnosis, 418.
Temperance hospital in Chicago, 422; instruction in the public schools, 299.
Tendon phenomena, 929.
Tendons, rupture of, 987.
Tenement-house Commission, legal victory for the, 22; conditions in New York, 942.
Tent life for consumptives, 395.
Teratoid tumors, neuroglia tissue and ependymal epithelium in, 426.
Teschner, Jacob, the present status of the treatment of lateral curvature, 1008.
Testis, strangulation of the, by torsion of the cord, 434.
Tetanus, antitoxin treatment of, 510; ascarides causing, 96; bacilli of, in blank cartridges, 62; etiology of so-called rheumatic, 789; following Fourth-of-July injuries, 61, 381; head, with peculiar etiology, 30; lesions that augment the development of, 705; nervous lesions in, 69; prevention of, 700, 756; prophylactic injections of antitoxin of, 28; traumatic, 456.
Tetany, gastric, 786.
Thalassotheraphy, abuse of, 951.
Thermal springs in Asiatic Turkey, 424.
Thomburgh, Robert M., the suprapubic operation for the medical cure of varicocele, with report of 18 cases, 334.
Thrombosis of femoral veins following aseptic laparotomy, 613.
Thrush, general infection in, 468.
Thymus gland, relation of, to marasmus, 428.
Thyroid, surgery of the, 755.
Thyroidectomy, fatal cases of partial, 29.
Thyroiditis, angina complicated with acute, 748.
Tic douloureux from intranasal pressure, 557.
Tick fever, 547; in Uganda, 314.
Tissue fluid, circulation of, in man, 624.
Tobacco, a study of the noxious effects of, 103; some of the effects of, 1012.
Tongue, growth beneath the, in infants, 469; hairy, black, 145, technique of operations on the; 637.
Tonsillar hemorrhage, 999.
Tonsils as a portal of tuberculous infection, 911; complications of hypertrophy of the pharyngeal, 587; hemorrhage following various methods of removal of the, 600; lipoma of the, 553; removal of the, 149, 535, 908; Vincent's ulcer of the, 377.
Toronto University, opening of the new medical department of 620.
Torticollis, spasmodic, relieved by operation, 32.
Tousey, Sinclair, the Röntgen and Finsen rays, electrolysis, galvaaism, faradism, high-tension discharges, and diagnostic illumination, 648.
Townsend, Terry M., abnormal frequency of urination treated with epidural injection, 486.
Toxin and antitoxin, attack on Ehrlich's theory, 789; quantitative and qualitative relations of, 706.
Trachoma, electricity in, 593; surgical treatment of, 816; subtropical, 266; treatment of, 207.
Traffic in cities, 419.
Treves, retirement of Sir Frederick, 22.
Trichiniasis, diagnosis of, 1025.
Trophoneurosis of the lower extremity, 188.
Tropics, disease and hygiene in the, 269, 313; nostalgia and melancholia in the, 788; physical requirements for residence in the, 139.
Trypanosoma brucei, cultivation of, 868.
Trypanosomiasis, 313, 338; study of, 462.
Tsetse fly disease, susceptibility of domestic animals to, 389.

# WATCH PATIENT'S WEIGHT

No progress in tubercular and neurotic cases can be expected while the patient's weight continues to decline. *Prescribe Hydroleine.* Plain cod-liver oil and ordinary emulsions fail because the patient's digestion is too much impaired to endure them.

Hydroleine is based on sound, scientific principles. It presents fat in a form easily digested and assimilated, and *fat* is what such patients need. Prescribe Hydroleine and you will get favorable results.

*Literature sent on application. Sold by druggists generally.*

"Mulford's Antitoxin Saves Most Lives"

# Don't Experiment With Imitations

OF

## Mulford's Serum-Syringe

## For Administering Diphtheria Antitoxin

You know Mulford's Antitoxin—what it has done and can be depended upon to do; and you know how surely imitations fall short of the original, because they haven't the creative spirit behind them that makes standards.

You know how we have stood, from the beginning, for better, and surer, and safer Antitoxin and methods of using it.

## Facts

1.—We were the first American firm to prepare a reliable Diphtheria Antitoxin.

2.—We were the first to offer Antitoxin of a high unit strength.

3.—We first protected absolutely the strength and efficiency of Antitoxin by dating each package, ensuring a reliable product.

4.—We originated the standardization of Antitoxin, so that each cubic centimeter of serum contained a fixed and definite number of Antitoxin units.

5.—We devised the first serum-syringe package for administering Antitoxin. Our Aseptic Glass Syringe was introduced in 1902, and has overcome every obstacle for the easy and prompt administration of Antitoxin. Air never comes in contact with the serum, nor is it possible to inject air into the patient.

**Every advance in the scientific production and method of administration of Antitoxin has been originated by us. We are the largest producers in the world.**

So, whenever an imitation of Mulford's Antitoxin and Syringe is offered, ask yourself: Will it do the work as surely? Is it thoroughly aseptic? Is an imitation ever as good as the original?

---

# ASSIMILATION

The growing child needs strength.
The busy man or woman needs strength.
The invalid or convalescent needs strength.
Nature's strength comes from food.

## Malta-Vita

The Perfect Family Food

contains the natural food elements in exactly the correct proportions.

It is pure wheat, thoroughly cooked, impregnated with diastase of barley, and then daintily flaked and toasted.

It contains more easily digested and quickly assimilated strength than any other known food.

The most delicate digestion will assimilate Malta-Vita perfectly.

You will find it the perfect food for assimilation.

A full-sized package will be sent free to any physician upon request.

# CATARRHAL CONDITIONS DEMAND OIL

There is nothing that acts so efficiently in acute or chronic catarrhal conditions of the respiratory tract as petroleum in its highest purity as represented by

# Terraline

**The Reason Why:**—The action of purified petroleum on the respiratory tract has been studied experimentally and clinically by numerous authorities.

(1) **It acts as a Solvent of Secretion.**
(2) **It Lubricates and Removes Irritation.**
(3) **It Reduces Swelling, Congestion and Inflammation of the mucous membranes.**
(4) **It Antagonizes Germ Action.**

This is why Terraline is unexcelled in its efficiency in relieving and curing cough of the most persistent character. It is indicated in chronic bronchitis, winter cough, whooping cough, tuberculosis, bronchial asthma, etc.

Besides, in virtue of its high potential energy, it is a food and tissue-builder absolutely without equal. It assists digestion and assimilation of other foods, and prevents fermentation and constipation.

TERRALINE is put up in 12-oz. bottles only (*never sold in bulk*), and may be obtained at all first-class prescription druggists.

A bottle will be sent to Any Physician paying Express Charges.

# A TEXTBOOK ON THE PRACTICE OF MEDICINE

## Designed for the Use of Students

By JAMES MAGOFFIN FRENCH, M.D.,

Lecturer on the Theory and Practice of Medicine, Medical College of Ohio; Attending Physician, St. Mary's Hospital; Consulting Physician, St. Francis Hospital for Incurables, Cincinnati.

This is a complete textbook of 800 compact pages. It is, in size at least, a reversion from the prevalent custom of adding to the labors of the student by constantly increasing the dimensions of his textbooks. The work is in no sense elementary, but discusses with commendable fulness all the subjects embraced in the more expanded treatises. The additional space has been saved, not by omissions, but by the employment of a more comprehensive and concise style of composition, the avoidance of all unnecessary repetition, and the omission of case reports, which are not considered of much value. The descriptions are lucid, the statements concise, and the language simple. Scientific terms are defined when their meaning is not apparent from the context. The student is not assumed to possess preliminary knowledge of the subjects discussed. The book is divided into three parts.

Part I is an introductory chapter which the author has designated "Principles of Medicine." The chief purpose of this part is the definition of terms as a means or ready reference for the student.

Part II embraces the systematic study of diseases—the Practice of Medicine as it is usually presented in the textbooks. While the author has carefully presented in this part all the well-established facts of medicine, he also states with fairness the principal theories when these are essential and when the facts remain undemonstrated. Prominence is given to all the latest discoveries in the domains of bacteriology and experimental medicine, including malaria, dysentery, yellow fever, the micrococcus of rheumatism, the studies of Duval and Bennett in cholera infantum, the parasite of smallpox, the newer pathology of diabetes, the recent studies of arthritis deformans, and the investigations of Dunbar in hay-fever, including mention of his recently announced serum. The book has, indeed, the great advantage of having been written in the full light of these discoveries, and it is consequently free from the discrepancies which necessarily cling to a work that has been repeatedly revised in the attempt to keep it abreast of the rapidly advancing sciences.

Part III treats of the more generally used and most reliable methods of clinical examination, including the examination of the blood, stomach-contents, intestinal discharges (with methods of disinfection), the urine and sputum.

The book is tastefully, though not profusely, illustrated, many of the cuts being made from the author's original drawings. The index is remarkably complete.

**French's Practice of Medicine consists of one volume of 800 pages, octavo, illustrated by 10 full-page plates in black and colors, and numerous engravings in the text.**
**Price, Extra Muslin, $4.00 *net;* Leather, $4.75 *net.***

By CHARLES WARRENNE ALLEN, M.D.,

Consulting Genito-urinary Surgeon to the City Hospital; Consulting Dermatologist to the Randall's Island Hospital; to the Hackensack Hospital; to the Bayonne Hospital; to the Infant Asylum of the Holy Rosary. Professor of Dermatology at the New York Post-Graduate School, etc.

SECOND EDITION, REVISED AND ENLARGED

ARGUING that there is an abundance of text-books, students' manuals and systems of medicine from which to supplement, this work is presented to the busy practitioner as affording a quick method of securing the views of the leaders in medical thought. In this respect it is practically a condensed system, representing the writings of a large number of eminent authors. By giving in succession the recommendations of several equally distinguished authors, the reader is enabled to select the one he will follow; or if one plan of treatment does not succeed another may be tried.

The revised edition of the PRACTITIONER'S MANUAL is placed before the medical profession without apology, as the very flattering reception accorded the former large edition amply justifies the present one.

The book is a large octavo of 893 pages, handsomely printed on super-calendered paper. Descriptive circular and sample pages on application. Price, bound in muslin, $6.00 *net;* half morocco, $7.00 *net.*

**Sent, post-paid, to any address on receipt of the price.**

## A Reliable Emmenagogue

# APIOLINE

(CHAPOTEAUT)

The true active principle of Parsley, differing from the so-called Apiol. Dispensed in spherical capsules of 20 centigrammes.

CHAPOTEAUT. PARIS, FRANCE. U. S. Agents, E. FOUGERA & CO., N.Y.

**In Amenorrhoea**

one capsule two or three times a day, given a week preceding menstruation, rarely fails to induce a normal flow.

**In Dysmenorrhoea**

amenable to internal remedies, the suppressed, irregular or painful menstruation is promptly relieved.

# Santal-Midy

OL. SANTAL. FLAV. (MIDY)

**NOTICE:**

Physicians who have successfully used "Santal-Midy" in Catarrh of the Bladder, Cystitis and Urethritis for the last 12 years, are liable to lose faith in this most valuable drug, on account of the extensive substitution of cheaper brands of capsules, with which the market is flooded.

The standard oil distilled by Midy's process from a *certain* kind of Mysore sandal wood, is dispensed in 5 minims capsules bearing the name "Midy." This is a guarantee against the substitution of the commercial oil of sandal from Mysore, Timore, and Western Australia.

# EFFICIENCY EXCELS

This is the conclusion of every Physician prescribing . . . .

# NEUROSINE

Clinical experience has proven that NEUROSINE is the **most efficient Neurotic, Anodyne and Hypnotic**

**Indications:**—Neurasthenia, Insomnia, Hysteria, Chorea, Migraine, Neuralgia, Restlessness of Fevers, Alcoholism, Asthma, Opium or Morphine Habit, Nervous Exhaustion, Epilepsy Before and After Surgical Operations, Convulsive and Reflex Neuroses, etc.

## COMBINATION

**Many Doctors Combine Dioviburnia** and NEUROSINE (equal parts) in Dysmenorrhea, Female Neuroses, Ovarian Neuralgia, Uterine Congestion, etc.

Full size bottle of each, free, to Physicians (who have not already received same) desirous of giving DIOVIBURNIA and NEUROSINE an impartial trial, they paying the express charges.

**DIOS CHEMICAL CO., - St. Louis, Mo.**

# ALLOUEZ MAGNESIA (The Triple Bi-carbonate)

Promotes the activity of the kidneys, increases the elimination of urea, and converts the acids into soluble form.

***Allouez is indicated in Diabetes, Nephritis, Rheumatism, Gout and Lithemic Conditions.***

The pernicious toxic products of imperfect metabolism are promptly eliminated by the solvent action of this natural diuretic. *IT RESTORES NORMAL ACTION* to the kidneys, liver, heart and blood vessels. *THE GATHERING OF* insoluble particles in the form of gravel in the kidneys and bladder is prevented by the continued employment of *ALLOUEZ*. *IT IMPROVES DIGESTION* quickly, and decreases acidity. The usefulness of Allouez covers a wide sphere.

# THE IRRIGATION TREATMENT OF GONORRHŒA

**Its Local Complications and Sequelæ.**

**By FERD. C. VALENTINE, M.D.,**

Professor of Genito-Urinary Diseases, New York School of Clinical Medicine; Genito-Urinary Surgeon, West Side German Dispensary; Genito-Urinary Consultant to the United Hebrew Charities, to the Metropolitan Hospital and Dispensary, etc., etc.

The general practitioner, especially in the smaller communities, must be a specialist in all branches of medicine, yet he has not the time to pursue exhaustive studies in all directions, nor, if he had, would the literature or clinical material be available. It was with this end in view that the author was asked to prepare the present book. The book is essentially a practical one, and, with its help, the general practitioner should have no difficulty in mastering the technique of the Irrigation Treatment, and in employing the treatment intelligently in the cases which may come before him.

In addition to the section on Irrigation Treatment, there are concise but comprehensive chapters on the complications of Gonorrhœa and on its sequelæ. In fact, the book is a complete treatise on Gonorrhœa.

**Complete in one volume of 220 pages, 8vo. Profusely illustrated by original drawings of manipulations, instruments, etc., etc. Bound in extra muslin. Price, $2.00 net.**

**WILLIAM WOOD AND COMPANY,**
**51 Fifth Avenue, - - - - - New York.**

# Success Signs Worth Heeding

**The regulation of the prima viæ is one of the essential basal principles of all therapeutics. Build on this as a sure foundation.**
**CLEAN OUT; CLEAN UP; KEEP CLEAN**

**TO "CLEAN OUT" USE ABBOTT'S SALINE LAXATIVE.**

An ideal effervescent laxative or cathartic, according to dose used. It is pleasant to take, promptly efficient, and never gripes. In the rheumatic diathesis use Abbott's Salithia,—Tartrate of Lithium, in effervescent combination with colchicine. It is both pleasant and efficient.

**TO "CLEAN UP" USE THE W-A INTESTINAL ANTISEPTICS.**

A mixture of the chemically pure sulphocarbolates and the most perfect antiseptic for the alimentary canal yet devised. Try the W-A Vaginal Antiseptic for Leucorrhoea. It is the basis of the most successful treatment of Typhoid Fever and all enteric infective conditions; is a good thing in the right place.

**TO "KEEP CLEAN" eat properly, live right and continue the use of the above as indicated.**

I find your Saline Laxative the pleasantest and most efficient of all the Salines I have used.
New York. Dr. J. B. C.

Your "Salithia for Rheumatism" is a good hit. It hits the spot—pleasant and efficient.
Chicago. A. L. R., M. D.

The W-A Intestinal Antiseptic in my hands is the *sine qua non* in all bowel affections.
Kansas City. Dr. D. R. W.

My experience with your W-A Vaginal Antiseptic is very gratifying. Am also having excellent results from the use of your "Candle Bougies" in Gonorrhoea.
Chicago. Dr C. M. C.

# ATLAS OF VENEREAL AND SKIN DISEASES.

SECOND EDITION

With additional new plates and half-tone engravings.

TEXT ENTIRELY REWRITTEN BY

**JAMES C. JOHNSTON, A.B., M.D.,**

Physician for Clinic of Skin and Genito-Urinary Diseases, Presbyterian Hospital; Dermatologist to Lying-in Hospital; Formerly Instructor in Dermatology, New York Polyclinic and Post-Graduate Medical School.

WITH THE ADDITION OF CHAPTERS ON ACUTE AND CHRONIC GONORRHEA BY

**GEORGE KNOWLES SWINBURNE, M.D.,**

Instructor in Genito-Urinary Surgery, Cornell University Medical College; Surgeon to Good Samaritan Dispensary.

*Among the distinguished gentlemen who have contributed selections from their collections of original illustrations may be mentioned: Kaposi, Neumann, Hutchinson, Fournier, Hardy, Ricord, Vidal, Leloir, Morrow, Keyes, Hyde, Piffard, Johnston, Hebra, Murchison, Priest, Allen, Casenave, Montmija, Unna, Robinson, Araujo, Ouchterlony, and others.*

SINCE the work originally appeared, rapid and, it is believed permanent advance has been made, in both venereology and dermatology; great changes in therapeutics and important developments as the result of skilful investigation necessitating such extensive changes that the editor of this revision deemed it best to write an entirely new text, thereby bringing the work up to date in every respect.

Dr. George K. Swinburne has contributed two new chapters on Acute and Chronic Gonorrhea, a subject which was not considered in the earlier form of the work, and which the distinguished author of that part is especially fitted, by great experience, to handle with exceptional ability.

Every physician will realize the importance and usefulness of pictorial representations of diseases of the skin as an aid to their ready recognition and differential diagnosis, and especially so to the vast majority of the profession, who are practically excluded from opportunities for clinical study, such as can be found only in the larger cities.

The examples selected for illustrations are not unusual or extraordinary conditions, so much as characteristic and typical examples of the diseases which commonly occur. The text includes the essential facts relating to the symptoms, diagnosis, and treatment, special attention being given to the latter. The plates are believed to be superior to anything of the kind heretofore produced, the coloring, which is one of the most essential features, being far superior to effects produced by any other process.

Altogether, considering the reputation of the authors of the plates, the ability of the editor, the artistic execution of the plates, the large size of the page, etc., etc., this ATLAS OF VENEREAL AND SKIN DISEASES is the most superb work in medical literature ever published in the English language.

A magnificent thick imperial folio volume (16½ x 12½ inches), which includes 240 pages of text, containing numerous half-tone engravings and **seventy-seven superb colored plates**, with several hundred figures, reproduced in the highest form of chromo-lithography. The work is sumptuously bound in half morocco. Price **$25.00.** Further particulars, including advantageous terms to purchasers on credit, will be supplied upon application.

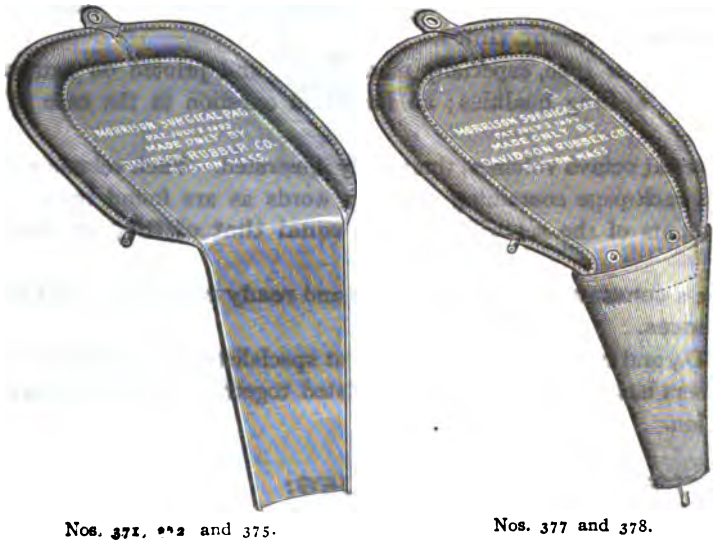
# Morrison Surgical Pads



Nos. 371, 372 and 375. Nos. 377 and 378.

THESE Cushions are especially adapted for use on the operating table or Physician's office chair.

They are made of the best tan rubber, and are provided with an inflatable air cushion four inches wide at the upper end, and on the sides.

These Cushions possess *many advantages* over any other Surgical Cushion on the market. FIRST—*a very important one*, that the Cushion is made in such a manner *that it has no space or crevice between the cushion and the pad*, and when not inflated the whole pad is perfectly flat and smooth, *easily sterilized and thoroughly cleansed.*

The SECOND advantage is, that the Cushion being made in the manner as described above, *can be used on both sides*, which will be a great saving to Doctors who have to use many of them.

# SEVEN VOLUMES NOW READY.

# Reference Handbook of the Medical Sciences.

## AN ENTIRELY REWRITTEN AND COMPLETELY REVISED EDITION.

**To be published in EIGHT IMPERIAL OCTAVO VOLUMES, illustrated by chromo-lithographs and over five thousand engravings.**

NO apology is deemed necessary in introducing to the medical profession the forthcoming revised edition of this great reference work, the sale of whose former edition far exceeded that of any other medical encyclopædia ever published. It is believed that the new Handbook will be welcomed not as a new and untried venture in medical book publishing, but rather as an old friend and ally, so much superior both in scientific completeness and mechanical execution as to render it indispensable alike to those who owned the original edition and learned by actual experience how great was its practical value, and to those who now for the first time will make its acquaintance.

This superb work covers so wide a field, and embraces such a large variety of topics, as to make it of the **greatest practical utility**, not only to general practitioners, but also to those who are interested more particularly in special departments of medical knowledge.

THE WORK CONSISTS OF A COLLECTION OF CONCISELY WRITTEN ESSAYS ON ALL THE IMPORTANT TOPICS BELONGING TO THE BROAD DOMAIN OF MEDICINE, SURGERY, AND THE ALLIED SCIENCES.

Its subject-matter is alphabetically arranged, thus admitting of instant and ready reference, with no loss of time in reading over page after page to find the precise item desired.

The topics are treated in such a thorough manner that the reader will rarely, if ever, find it necessary to consult larger special treatises or monographs for the information of which he may stand in need.

The great advance made in the quality of **illustrations**, through the discovery of new processes and the perfecting of mechanical technique, as well as from the greater experience and taste of those now superintending such matters, are apparent in the Reference Handbook. A great number of full-page plates, by chromo-lithography, photogravure, and other processes, is to be inserted. No pains or expense has been spared to make this work **the most sumptuously illustrated publication of recent times.**

The Reference Handbook is electrotyped from new type, especially made for it, and printed on extremely fine paper, which combines a high surface with the best wearing qualities; an important question in the case of a work of this sort.

The work will consist of eight splendid imperial octavo volumes, thoroughly illustrated. Each volume will contain about 800 pages, printed in double column, and each page containing as many words as are found upon three and one-half ordinary full octavo pages. The contents of the set will therefore **equal that of fifty or more large volumes of the usual octavo size.**

The Reference Handbook is designed to be a **constant daily companion** and **ready reference** on **all branches of Medicine, Surgery**, and the **collateral sciences.**

The Editor-in-Chief is Albert H. Buck, M.D., and over five hundred eminent specialists have agreed to contribute. No such number of prominent writers and teachers has ever before been associated together in the preparation of a work specially designed for the medical profession.

***SOLD BY SUBSCRIPTION AT THE FOLLOWING PRICES:***

# HYDROTHERAPY

A GUIDE TO THE APPLICATION OF WATER IN DISEASE

For Students and Practitioners of Medicine

By SIMON BARUCH, M.D.

Octavo, 506 pages, profusely illustrated. Extra muslin, $4.00 *net.*

WILLIAM WOOD & COMPANY, Publishers, - NEW YORK

# MEDICAL COLLEGES.

## College of Physicians and Surgeons.

Standard requirements. Allowance for service in Dispensary and Hospital. Twenty-second year opens September 17th. Ample instruction in actual practice.

J. H. JACKSON, A.M., M.D., Registrar, Near City Hospital, Shawmut Ave., Boston, Mass.

## The Baltimore Medical College

Preliminary Fall Course begins September 1, 1903.
Regular Winter Course begins September 24, 1903.

Excellent Teaching Facilities; Modern College Buildings; Ideal Lecture Hall and Amphitheaters; Large and Completely Equipped Laboratories; Capacious Hospitals and Dispensary; Lying-in Department for Teaching Clinical Obstetrics; Large Clinics. Send for Catalogue, and address

DAVID STREETT, M.D., Dean, 712 Park Avenue, Baltimore, Md.

## Yale University.

The curriculum in the Medical School of this University is graded to extend through four years, and consists chiefly of *personal instruction* in Classroom, Laboratory, and Clinic with didactic lectures on certain branches.

The ninety-second annual session will begin September 29, 1904, and continue thirty-five weeks, exclusive of vacations.

For announcements of the curriculum, requirements for matriculation and graduation, apply to

DR. HERBERT E. SMITH, Dean,
Yale Medical School, New Haven, Conn.

## Tufts College Medical School

**Boston, Mass.**

For men and women, is the only regular co-educational medical school in New England recognized by the Mass. Med. Soc. Four years' course. Entrance examinations required. Will commence its regular sessions on the first Wednesday in October. Address the Secretary, DR. C. P. THAYER, Tufts College Medical School, Boston, Mass.

## Albany Medical College.

MEDICAL DEPARTMENT, UNION UNIVERSITY
1903—1904.

ALBANY, N. Y.

Regular Term begins September 22, 1903, and closes May 3, 1904.

Instruction by Lectures, Recitations, Clinics, Laboratory Work, and Practical Operations. Hospital and laboratory advantages excellent.

Catalogue and Circulars containing full information sent on application to

WILLIS G. TUCKER, M.D., Registrar,
Albany Medical College, Albany, N. Y.

## BOWDOIN COLLEGE

MEDICAL DEPARTMENT

The Eighty-fourth Annual Course of Lectures will begin December 24, 1903, and continue twenty-six weeks.

Four courses of lectures are required of all who matriculate as first-course students.

The courses are graded and cover Lectures, Recitations, Laboratory Work and Clinical Instruction.

The third and fourth year classes will receive their entire instruction at Portland, where excellent clinical facilities will be afforded at the Maine General Hospital.

For catalogue apply to

ALFRED MITCHELL, M.D., *Dean.*
BRUNSWICK, MAINE, July, 1903.

## WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

53d Annual Session. Thorough course. Four years. Exceptional facilities for Laboratory and Bedside Instruction. Full particulars in catalogue.

CLARA MARSHALL, M.D., Dean, Box 325, 21st St. & N. College Ave., Philadelphia, Pa.

## College of Medicine, Syracuse University.

A new building has spacious laboratories exceptionally well lighted and equipped. A cold-storage plant supplies an abundance of odorless anatomical material at all seasons of the year. Special attention is given to individually practical clinical instruction in hospitals, asylums, and a dispensary.

For an ANNOUNCEMENT address
THE TREASURER,
307, 309, and 311 Orange St., Syracuse, N. Y.

## CHICAGO POLICLINIC AND HOSPITAL

Pioneer Post-Graduate School of the West.

Regular Fall and Winter session will be resumed September 15th. Large Clinics, unexcelled Hospital facilities and instruction by a corps of the leading specialists of Chicago, ensure the practitioner rare opportunities for post-graduate work under the very best auspices.

For announcement, schedule and full information, address M. L. HARRIS, M.D., Sec'y, 174-176 E. Chicago Ave., Chicago, Ill.

## University of Colorado,

MEDICAL DEPARTMENT,
BOULDER, COLORADO.

The next session begins September 14, 1903 and continues for nine months.

The course of instruction extends through four years of nine months each.

The University possesses special advantages in its fully-equipped laboratories for the work in Anatomy, Physiology, Chemistry, Histology, Materia Medica, Pathology, and Bacteriology.

The tuition is $50.00 per year. There are no extra fees.

For further information apply to
LUMAN M. GIFFIN, M.D., Dean,
Boulder, Colorado.

## THE NEW YORK EYE AND EAR INFIRMARY.

**School of Ophthalmology, Otology and Laryngology.**

FOR GRADUATES OF MEDICINE.

Clinics daily by the surgical staff of the Infirmary. Special course in Ophthalmoscopy, Refraction, Operative Surgery of the Eye and Ear, and Pathology.

The abundant clinical material at this well-known institution affords students an unusual opportunity for obtaining a practical knowledge of these special subjects. Two vacancies on the House Staff exist in January and July of each year. For particulars address the Secretary,

DR. W. E. LAMBERT,
New York Eye and Ear Infirmary.

## HARVARD UNIVERSITY,

MEDICAL DEPARTMENT.

A School for Graduates in Arts or Science.

The course of study required for the degree of M.D. is of four years' duration. The next year begins September 29, 1904, and ends on the last Wednesday in June, 1905.

*Courses for Graduates.*—These courses of instruction are offered for graduates of recognized medical schools, and are given in subjects embracing all the branches of practical and scientific medicine.

The extensive laboratories of the school are inferior to none, and the clinical advantages afforded by the hospitals of Boston are unsurpassed.

*Summer Courses.*—During the summer, courses in many branches of practical and scientific medicine are given by teachers in the school to both medical students and graduates.

Facilities for research work are offered in all of the laboratories.

For announcements of the Required Courses of Study in the School, the Courses for Graduates, and the Summer Courses, address Dr. Wm. L. Richardson, Dean, Harvard Medical School, 688 Boylston St. Boston Mass.

## UNIVERSITY OF VERMONT.

MEDICAL DEPARTMENT.

FIFTY-FIRST ANNUAL SESSION.

This department of the University offers to students of medicine an opportunity to obtain a thorough course of modern instruction at a moderate expense. Four years' course, December 1st to July 1st. Write for catalogue giving full particulars. Address DR. B. J. ANDREWS, Secretary, Mary Fletcher Hospital, Burlington, Vt.

## Northwestern University Medical School.

(CHICAGO MEDICAL COLLEGE.)

The regular course includes four years of eight months each. The laboratory equipment is complete. The clinical facilities are exceptionally fine. For circulars of detailed information, address the Secretary,

DR. ARTHUR R. EDWARDS,
2431 Dearborn Street, Chicago, Ill.

## Western Pennsylvania Medical College, Pittsburgh, Pa.

Session of 1903-1904. Eighteenth Year.

MEDICAL DEPARTMENT OF THE WESTERN UNIVERSITY OF PENNSYLVANIA.

Graded Courses of Eight Months, Commencing October 1st, 1903.

Four years required. Instruction practical. Superior clinical advantages offered students. College and Clinic buildings commodious. Extensive Laboratories and Apparatus. Hospital Medical Clinics and Ward-bedside Clinics, Surgical, Operating and Maternity, and Dispensary and Out-door Clinics daily. Laboratory work continuous. Quizzes regular.

For particulars address

Prof. J. C. LANGE, M.D., Dean,
129 Ninth Street Pittsburgh, Pa., or
Dr. W. J. ASDALE, Secretary Board of Trustees,
5523 Ellsworth Avenue, E. E., Pittsburgh, Pa.

## Jefferson Medical College of Philadelphia.

### New College Building and New Laboratories.

The Seventy-ninth Annual Session will begin September 24th, 1903, and continue eight months. For four annual sessions the curriculum provides without extra fee: 1. Practical manual training in ten different laboratories recently fitted up at heavy cost. 2. Recitations by the faculty and others. 3. Didactic lectures and demonstrations in the commodious new buildings. 4. Clinics and bedside ward work in small groups at the College Hospital; beside the clinics given by the staff of the college at the Pennsylvania, Philadelphia, German, St. Joseph's and Municipal Hospitals. 5. Lying-in cases at the College Maternity.

A NEW FIRE-PROOF HOSPITAL with unrivalled facilities for clinical teaching is now building at a cost of $700,000.

For circular and information, address
J. W. HOLLAND, Dean

## Aphorisms, Definitions, Reflections and Paradoxes.
MEDICAL, SURGICAL AND DIETETIC.

BY A. RABAGLIATI, M.A., M.D., F.R.C.S.

The position of medicine is depressing—the confusion of its nomenclature, its want of definiteness, its cross-divisions discouraging, as also the conflict of opinion, and therefore of practice, among even the most distinguished of its exponents. In these aphorisms, attention has been directed to a few simple and fundamental facts which occur in the organism.

One volume, 305 pages, octavo. Price, bound in muslin, $2.50 net.

WILLIAM WOOD AND COMPANY, New York.

## FRENCH; TEXT-BOOK ON THE PRACTICE OF MEDICINE

8vo, 800 pages, illustrated by plates and engravings. Cloth, $4.00 net. Leather, $4.75 net.

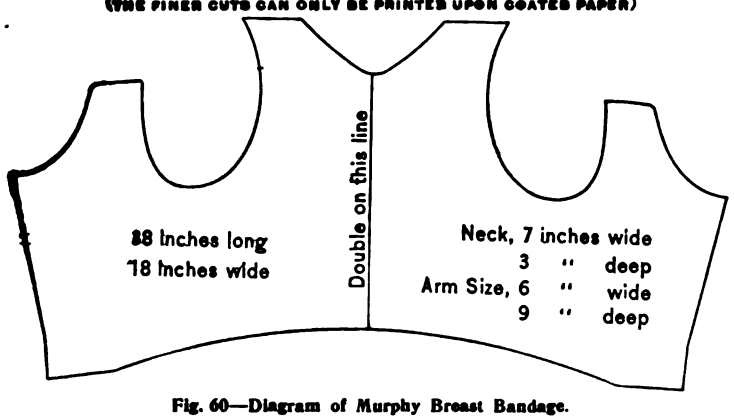
# THE PRINCIPLES OF OBSTETRICS

## A Practical Manual for the Student and General Practitioner

By STANLEY PERKINS WARREN, M.D., Portland, Me.,
Obstetric Surgeon to the Maine General Hospital,
Consulting Physician to the Maine Eye and Ear Infirmary; etc., etc.



SAMPLE "LINE" ILLUSTRATION
(THE FINER CUTS CAN ONLY BE PRINTED UPON COATED PAPER)
Double on this line
38 inches long
18 inches wide
Neck, 7 inches wide
3 " deep
Arm Size, 6 " wide
9 " deep

Fig. 60—Diagram of Murphy Breast Bandage.

This work has been written to provide the student with a complete reliable textbook, covering the whole ground as embraced in the curricula of most schools, with all the fulness necessary to clearness, but omitting everything not essential or practical. Theories, unless well demonstrated, are considered as of minor interest to the student. The aim has been to present the essential facts in plain and simple form, that the undergraduate may acquire the science and art more in the shape it will assume when put to practical use. It is the most compact textbook of obstetrics published.

The book will possess the additional advantage of a working hand-book adapted to the requirements of private practice, where the refinements of hospital instrumentation and nursing are conspicuously absent. It teaches that aseptic midwifery is possible under the restrictions of the private home, with the simpler armamentarium of the obstetrical handbag.

The work is superbly illustrated The cuts, which are very numerous, are all original or redrawn and re-engraved. Many of them are from original photographs by the author, and are very beautiful. No trouble or cost has been spared on the cuts, and the pictures *illustrate*, as well as please. The volume is handsomely printed, on coated paper.

**Octavo; 385 pages; Superbly illustrated by 165 line and half-tone engravings.**
**Cloth; $3.00 *net*. Leather; $3.75 *net*.**

**DIFFERENT**
Huston's New Curette differs radically from all other patterns.
It differs in almost every respect:—Shape, size, length and material. There is nothing on the market "just as good as." It is a serious error to suppose that some other instrument is "just about the same thing." This Curette is worth its weight in gold wherever curettage is indicated (endometritis, etc.); but its chief value is in abortions, miscarriages, and wherever there are retained and adherent membranes.
PRICE, $2.00. HUSTON BROS., 113 Adams St., Chicago

**THE PRIZE OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY, NEW YORK, WILL BE AWARDED AT COMMENCEMENT 1904.**

This is a Biennial Prize of five hundred dollars open for competition to the alumni of the above college. It is awarded for the best medical essay submitted upon any subject the writer may select.

The prize money is payable upon the filing with the secretary of a printed copy of the prize essay.

*An essay, in order to be held worthy of the prize must contain the results of original investigations made by the writer.*

This prize is not awarded to any essay which is the work of more than one author, or which is at the same time submitted for another prize.

Each competitor is required to send with his essay to the Prize Committee a statement that these requirements have been complied with.

Essays in competition for the prize to be awarded at commencement 1904 must be sent to the Secretary of the Alumni Association on or before April 1, 1904.

Competing essays must be marked with a device or motto, and accompanied by a sealed envelope similarly marked, containing the name and address of the author.

If no one of the competing essays be deemed sufficiently meritorious, the prize is not awarded.

DR. H. E. HALE,
Secretary of the Alumni Association of the College of Physicians and Surgeons,
150 West 59th Street, New York City.

## THREE GATEWAYS TO THE WEST.

Since the Southwest Limited, the new electric-lighted train of the Chicago, Milwaukee & St. Paul Railway, has been placed in service, Chicago to Kansas City, this company offers the best of train service to the West through three important gateways — Kansas City, Omaha and St. Paul.

The Pioneer Limited, Chicago to St. Paul and Minneapolis, for years has been the most popular train between these cities. The Overland Limited, Chicago to Omaha and San Francisco, is the most famous of transcontinental trains through Omaha.

The Southwest Limited, Chicago to Kansas City, with its standard and compartment sleepers, library-observation cars and other excellent equipment, offers travelers to the Southwest better service than they have heretofore enjoyed, and in consequence has proved a success from its initial trip.

# DO NOT FORGET

the importance of a remedy that pacifies the irritable stomach and intestines. This attribute of

# GRAY'S Glycerine TONIC Comp.

makes it the most valuable Summer tonic and reconstructive in malnutrition, nervous exhaustion and general debility.

THE PURDUE FREDERICK CO.,
No. 15 Murray Street, New York.

PROPER ADVICE ON INFANT FEEDING

The PROBLEM of ARTIFICIAL FOOD FOR BABIES

can never be perfectly solved until cow's milk that is absolutely pure can be obtained with never failing regularity and positive surety. This will probably never be, because even the very best methods of dairy inspection have been proven unreliable.

Physicians who have studied the subject most carefully declare that cow's milk, Pasteurized or Sterilized in

ARNOLD'S MILK STERILIZER AND PASTEURIZER

is the only practical solution of the problem. This Sterilizer is the most easily used and the only one that makes the process certain. No other agency has done so much toward preventing the bowel troubles that come with summer; no other invention has done so much toward lessening infant mortality. Its moderate price puts it within the reach of all.

The printed matter and reviews by leading specialists, which we would like to send you without charge, will convince you of the advisability of recommending this Sterilizer in every home where a baby is to be fed. Please write for it. All reputable Druggists can supply

Arnold's Sterilizer and Pasteurizer.

Wilmot Castle & Co., 1 Elm St. Rochester, N.Y.

LOOK BEFORE YOU LEAP.

The $150 or $200 you are about to put in a cheap machine will go a long way toward paying for a superior one.

The one will prove disappointing; the results you had expected will not materialize, and the machine will be relegated to the attic, cellar or barn.

The other will be a profitable investment, both from a therapeutical and financial standpoint.

The Morton-Wimshurst-Holtz Influence Machine

NEVER DISAPPOINTS.

*The Best Machine that Skilled Workmen and Money can Produce.*

VAN HOUTEN & TEN BROECK, 380 Fourth Ave., New York.

Makers of High-Grade Electro-Therapeutical Apparatus. Established 1876.

A Strong Reason

for prescribing Angier's Petroleum Emulsion as a nutritive tonic during the Summer months is that Petroleum is not subject to decomposition as are animal fats and oils. Hence

Angier's Petroleum Emulsion

*With Hypophosphites*

may be administered to adults and children when the gastro-intestinal tract is irritable, sensitive, or the seat of inflammation. No other remedy is so uniformly efficient in chronic diseases attended with loss of flesh and deficient vitality.

*Samples sent only upon request.*

ANGIER CHEMICAL COMPANY, (ALLSTON DISTRICT) BOSTON, MASS.

# VIN MARIANI INTRODUCED NEARLY HALF A CENTURY AGO:

"The Preparation which made Coca known as a remedy!"

## ONLY EXCLUSIVE COCA LABORATORIES IN THE WORLD

AT NEUILLY SUR-SEINE, PARIS, FRANCE, ESTABLISHED AND DIRECTED BY M. MARIANI.

## Priority, Facilities, Processes of Manufacture and Personal Supervision

**MAINTAIN MARIANI COCA PREPARATIONS INIMITABLE.**

**AVOID** "Coca Wines" Extemporaneously made with **Cheap Wine and Cocaine.**
These Substitutes harm both Patient and Physician and betray confidence in the unique properties of Coca.

**BECAUSE** of false wines foisted on the public in imitation of VIN MARIANI and because of the evil against a valuable remedy, Physicians urged us to denounce these frauds through overwhelming facts.

This being in a measure accomplished, **OUR COCA PREPARATIONS** are advertised exclusively to the Medical Profession in the same conservative manner that has enlisted ethical support.

# VIN MARIANI

**Represents only TRUE COCA with a Sound Nutritious FRENCH WINE; Invariably Uniform and Reliable.**

**AN ADJUVANT TO ALL OTHER REMEDIES IN**

## CONVALESCENCE—WASTING DISEASES—NEURASTHENIA

**And Allied Conditions from any cause.**

**THE COCA LEAF**

A PERIODICAL EPITOME OF CURRENT MEDICINE ADVOCATING THE RATIONAL USES OF COCA;
**MAILED FREE**
TO PHYSICIANS ON REQUEST.

Inquiries from the Profession receive prompt consideration.

MARIANI & CO.,

52 West 15th St., New York.

LABORATORIES: NEUILLY SUR-SEINE, FRANCE.

PARIS, 41 Boulevard Haussmann; LONDON, 49 Haymarket; BERLIN, 56 Charlotten Strasse; MONTREAL, 87 St. James Street.

## ELIMINANT ANALGESIA.

ELIMINATION AS A FACTOR IN RELIEVING PAIN.

THE ship of life, as it starts upon its voyage, is guided by an unseen captain, who, seated in the conning tower of the brain, with alert and sleepless eye, watches the signal-board of the nerves the intricate ramifications of which reach every danger-point in the delicate vital engine that throbs unceasingly all the years of life.

As through the optic nerve he views the outer world, so does this navigator through the telegraphic system of the nerves keep the entire machinery in steady motion and quickly observe the slightest need. Should fuel be required, the Pneumogastric nerve announces it and the "fifth" or Trigeminous nerve attends to the selection and mastication of the food.

Promptly observant of the injestion of fuel, its quality and adaptiveness, the Pneumogastric nerve sounds an alarm if the stomach is improperly charged; one by one the signals of pain ring on the keyboard of the conning tower and the captain orders the organs of elimination to do their duty. The eliminators should, however, always be engaged in carrying off the waste products of combustion, thus preventing congestion in various parts of the human economy, their particular attention to any part being usually called by a signal of pain or distress, otherwise all these valves work automatically.

It will be observed that pain is the usual sign of distress, and woe betide the unfortunate who is bereft of this beneficent signal. The relief of excessive pain should always be accompanied by a proper knowledge of its cause. Opiates like opium or morphine, though sometimes considered indispensable, are always injurious, because they interfere with the elimininators who are nine times out of ten busily at work removing the cause of the painful disturbance.

Elimination is acknowledged by all authorities to be as important a conservator of vital force as Ingestion, Digestion or Assimilation, and should always be taken into consideration when treating any disease, or pain from any cause.

A pain reliever should be also an eliminator and never a congester. Phenàlgin is among the very few Analgesic drugs that can be depended upon to relieve continued pain and at the same time not interfere with the normal eliminatory functions; it also being a glandular stimulant, first relieving pain and then aiding to carry off the cause. Too much stress cannot be given to this special feature of Phenàlgin as an Eliminant Analgesic. It is an idea pregnant with importance. It promises suffering relieved, elimination promoted and tranquility established without functional disturbances from the drug. Phenàlgin being a cardiac stimulant does not depress the circulatory system, and its eliminatory properties forbid it from ever inducing a habit like morphine, cocaine and kindred drugs. Its benign and soothing influences may be enjoyed without fear of untoward after-effects.

# MAIL-ORDER DRUGGISTS

THE SUMMER EXODUS to the seashore and country makes heavy demand on us for tourists' supplies, medicine cases, emergency chests, etc. We have already started our Quick Delivery Service to all points in New England. This service is familiar to our patrons through its successful workings in previous years. Prescriptions sent to us by mail, telephone or telegraph are filled and forwarded within an average of forty minutes from the time they are received. This is only possible because of the very extensive stock of drugs carried by us in our two stores. Six telephones in operation. A large corps of prescription clerks who do nothing but fill prescriptions. Special uniformed messengers to all important trains leaving the city; also to each express office. The filling of prescriptions is our specialty, and we save you every moment's delay that is possible. You secure the highest quality of drugs, absolutely fresh, and extra care in compounding.

**METCALF'S, 36 Court St., also Copley Square Sign of Big Clock**

**Boston, Massachusetts.**

Many physicians have found in cases of amylaceous dyspepsia, malnutrition and other disturbances of the digestive tract, that

**Mapl-Flake**

can be used with excellent results.

Large, crisp wheat flakes, steam-cooked and toasted to a delicious brown, and flavored with pure maple syrup.

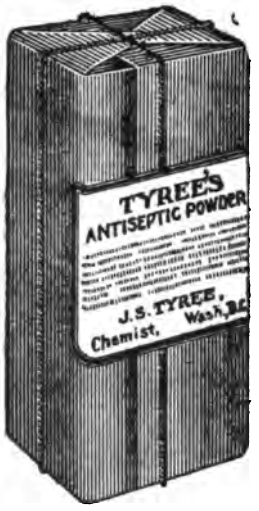
"I am recommending Mapl-Flake with good results to many of my patients who are suffering from weak stomachs and indigestion. It is also good for growing children. The peculiar manner of its preparation, the starch being thoroughly dextrinized, stamps it as the ideal food for everybody.

DR. WM. P. KIER,
3609 Lindell Boulevard, St. Louis, Mo.

Sold by all grocers at 15 cents a package. A sample package will be sent upon request to all physicians who are interested.

HYGIENIC FOOD CO., - - Battle Creek, Mich.

# Antiseptic Treatment of Dysentery



DYSENTERY IS A LOCAL DISEASE—
INFLAMMATION OF THE LOWER BOWEL

Its rational treatment is by the nearest and most convenient route—by antiseptic high irrigation per rectum.

The best agent for this purpose is a hot, copious, mild solution of

## Tyree's Antiseptic Powder

This should be repeated at frequent intervals, governed by the severity of the case.

Other intestinal disorders are much benefited by the same treatment, by which the reabsorption of inflammatory exudates is prevented.

TYREE'S ANTISEPTIC POWDER, first introduced for treatment of inflammation of the vagina, has proved to possess remarkable healing powers for ALL MUCOUS MEMBRANES.

*Washington, D. C.*

SEND FOR FULL LITERATURE AND SAMPLE

A child needs mineral substance to harden its bones and this is plentifully supplied in the hypophosphites of lime and soda contained in Scott's Emulsion. The cod liver oil provides the element of fat needed to reinforce the child's ordinary food. Thus Scott's Emulsion offers in a perfect combination the very principles of proper bone and flesh nourishment most needed by a young child.

Samples Free.
SCOTT & BOWNE, Chemists,
409 PEARL STREET,
New York.

# ISAROL.

A pharmaceutical preparation, manufactured by the **Society of Chemical Industry** in Basle.

Its physiological action may be classed under three heads:

I. Vascular astringent, antipyretic and alterative—
Employed in the form of paste undiluted, in rheumatism, pannus, etc.

II. Siccative and resolvent—
Employed as 10% Lanolin ointment, in burns, eczema, etc.

III. Antizymotic—
Employed as 10% Isarol-Collodion for treatment of erysipelas, etc., or a solution 40 to 60% in water—painted on.

Superior to Ichthyol and less expensive.

**A. KLIPSTEIN & CO.,**
**122 Pearl Street, - - New York City,**

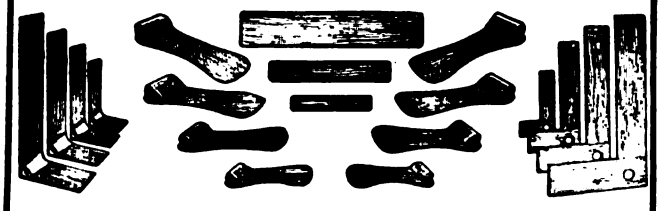
BOSTON, MASS. PROVIDENCE, R. I.
MONTREAL AND HAMILTON, CANADA.

# THE FULTON SPLINTS



4 Anterior Angular $5.00 8 Bond (4 Right and 4 Left)
4 Internal Angular SET 4 Prs. Straight Splints

For all Fractures of the arm and forearm.

**FEICK BROS. CO., - - PITTSBURG, PA.**
MANUFACTURERS OF SURGICAL INSTRUMENTS

# CARABAÑA

**Most Palatable and STRONGEST Natural Aperient Water**

**THE ONLY ONE**

**ALTERATIVE and ANTISEPTIC**

**Highly endorsed by the Paris and Madrid Academies of Medicine and many leading American Physicians.....**

Dr. J. K. CROOK, the Authority on Mineral Waters, says (in the Medical Record) that America presents no analogies to **CARABANA**, which he considers the Strongest of all Natural Aperient Waters.

Analysis and Comparative Statistics on application. If your Druggist cannot supply CARABANA, please address

*Details are wanting in several instances, either because dates are not yet fixed, or because no response has been made to our request for information.*

# The Sumbul Series No. 1

**Sumbul or Musk Root is conceded by those who have tested it's virtues to be a highly valuable drug. We have made a study of it for years, know its characteristics, and how to prepare it to the best advantage.**

**No such a condition as failure, if you will use**

## Warner & Co's Sumbul Preparations

**Quality and scientific manipulation, with us, STAND PRE-EMINENT.**
**Note the following desirable combinations prepared and issued for Doctors prescribing**

**PIL. SUMBUL COMP.**
(DR. COGSELL)
EITHER S. C. OR G. C.

℞ Ext. Sumbul, 1 gr. Asafetida, 2 grs.
Ferrous Sul. dried, 1 gr.
Arsenous Acid, 1-40 gr.
In each pill.

"WARNER & CO."

**PIL. SUMBUL COMP.**
(APERIENT—DR. SHOEMAKER)
EITHER S. C. OR G. C.

℞ Ext. Sumbul, 1 gr. Ext. Cascara, ½ gr.
Asafetida, 1 gr. Aloin, ¼ gr.
Ext. Nux Vom. ½ gr. Gingerine, ¼ gr.
In each pill.

"WARNER & CO."

**COMP. TABLETS**
**SEDATIVE COMP. MODIFIED**
UNCOATED OR COATED

℞ Ext. Valerian, 1 gr. Ext. Sumbul, 1 gr.
Ext. Cannabis Ind. 1-10 gr.
Ext. Henbane, ¼ gr, Asafetida, 1 gr.
In each tablet.

"WARNER & CO."

**Kindly bear in mind the essential specification "Warner & Co." and assure yourself of best results from the applied remedy.**

**WM. R. WARNER & CO.** PHILADELPHIA NEW YORK CHICAGO NEW ORLEANS

SAMPLES AND LITERATURE ON REQUEST

R. AND C.

**CHOLERA INFANTUM and kindred intestinal disorders are cured as well as prevented by the use of**

# PEPTENZYME

Peptenzyme is the only digestant that represents the digestive secretions physiologically as found in nature, and on this account a perfect digestant. All other digestive ferment products contain the active ferments of either Pepsin alone, or Pepsin and Pancreatin, isolated with chemicals, which greatly injure the digestive secretions. It not only aids but stimulates the normal digestive secretions. Remember it cures as well as gives relief.

SAMPLES AND LITERATURE ON REQUEST.

Send for anatomical chart and fee-table of our
PATHOLOGICAL, CHEMICAL and BACTERIOLOGICAL LABORATORIES

**REED & CARNRICK,**
42-46 Germania Ave., Jersey City, N. J.

# IODINE

## WITHOUT IODISM

***A New Departure***

***In Therapeutics***

Doctor, you have *nothing* that will reach the *respiratory diseases* or that stubborn case of *rheumatism, scrofula* in all its forms, and disorders of the *urinary tract* like

## BURNHAM'S SOLUBLE IODINE

Hundreds of physicians are testifying to the *truth* of the above assertion.

It is a pure *free* Iodine that will *not precipitate* or cause any *gastric irritation, every drop* of which is *equal* in *therapeutic value* to at least *fifteen grains* of Potassium Iodide.

Sample and literature sent on application.

Do not fail to try it and be convinced.

Price per 1 oz. bottle concentrated (500 doses), $1.00, postpaid.

**BURNHAM SOLUBLE IODINE CO.**

**11 PEMBERTON SQUARE, BOSTON, MASS.**

# X-RAY APPARATUS

Highest grade Induction Coils with mechanical or electrolytic interrupters; to be operated from storage battery, 110 volts direct current or alternating current.

Self-regulating X-Ray tubes, fluoroscopes and other accessory apparatus.

Complete outfits for fluoroscopic, radiographic and therapeutic use.

Our **working exhibit** can be inspected any week day (except Saturday) between 2 and 5 P. M. Other times by appointment.

State requirements and ask for descriptive matter.

**JAMES G. BIDDLE, 1114 Chestnut St., Philadelphia.**

# TRI-IODIDES (HENRY'S)

*LIQUOR SALI-IODIDES—Colchicin, 1-20 grain; Phytolaccin, 1-10 grain; Solanin, 1-3 grain; Soda Salicylate, 10 grains; Iodic Acid, equal to 7-32 grains Iodine; Aromatic Cordial. Dose, 1 to 2 drams in water. 8-oz. bottle, $1.00.*

A powerful alterative and resolvent, glandular and hepatic stimulant, and succedaneum to the iodides. Indicated in all conditions dependent upon perverted tissue metabolism; in lymphatic engorgements and functional visceral disturbances; in lingering rheumatic pains which are "worse at night." Bone, periosteal and visceral symptoms of late syphilis; for the removal of all inflammatory, plastic and gouty deposits.

A remedy in sciatica, megrim, neuralgias, lumbago and muscular pains; the gouty and rheumatic diathesis; acute and chronic rheumatism and gout; chronic eczema and psoriasis, and all dermatic disorders in which there is underlying blood taint.

An hepatic stimulant increasing the quantity and fluidity of the bile. Relieves hepatic and intestinal torpor; does not cause the unpleasant gastric symptoms of potassium iodide.

# THREE CHLORIDES (HENRY'S)

*LIQUOR FERRISENIC—Each dram contains: Proto-Chlor. Iron, 1-8 grain; Bi-Chlor. Mercury, 1-128 grain; Chloride Arsenic, 1-280 grain; Calisaya Cordial. Dose, 1 to 2 drams. 12-oz. bottle, $1.00.*

An oxygen-carrying ferruginous preparation, suitable for prolonged treatment of children, adults and the aged. Indicated in anemia and bodily weakness, convalescence from acute diseases and surgical operations; boys and girls at the age of puberty, and the climacteric period in women. In children with chorea, rickets, or who are backward in development, or in whom there exists an aversion to meats and fats. Prolonged administration never causes "iron headache."

As an adjuvant for potassium iodide, the undesirable manifestation known as iodism can be removed.

Stimulant to the peptic and hydrochloric glandular system of the stomach, especially serviceable in the impaired appetite, nausea, vomiting and other gastric symptoms of alcoholic subjects.

# MAIZO-LITHIUM

*LIQUOR LITHIUM MAIZENATE.—Nascent Chemic Union of Maizenic Acid—from Green Corn Silk—with Lithium, forming Maizenate-Lithium. Two grains to dram. Dose, 1 to 2 drams. 8-oz. bottle, $1.00.*

A genito-urinary sedative, an active diuretic; solvent and flush; indicated for the relief and prevention of renal colic; a sedative in the acute stages of gonorrhœa, cystitis and epididymitis; in dropsical effusions due to enfeebled heart or to renal diseases. As a solvent in the varied manifestations of gout, gouttiness and neuretic lithæmia, periodical migraineous headache, epigastric oppression, cardiac palpitation, irregular, weak or intermittent pulse; irritability, moodiness, insomnia and other nervous symptoms of uric-acidemia. Decidedly *better*, more economical, extensive in action and definite in result, *than mineral waters.*

Those cases of irritable heart, irregular or intermittent pulse so frequently met with by insurance examiners, and found to be due to excess of uric acid, are special indications for Maizo-Lithium.

**HENRY PHARMACAL CO., - Louisville, Ky.**

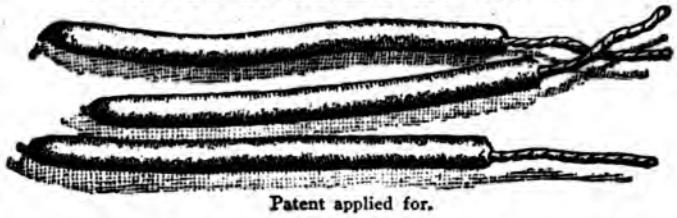
# GONORRHEA

**RELIEVED IN SIX TO TWELVE DAYS**

## Alkaloidal Treatment Practically Specific

The uncertainty, discouragement and dissatisfaction in the treatment of this very common disease is all done away with by our Special Alkaloidal treatment. This renders it not only possible but easy to treat these cases successfully and promptly.

**PERFECT DRAINAGE BY USE OF**



Patent applied for.

## The Candle (Drainage) Bougie

**Accomplishes this. It is double medicated, the outer layers being Antiseptic and Emollient, and the Wick Antiseptic and Astringent.**

(Medicated Drainage Cotton encased in Medicated **Solidified** Glyco-Magnesia with Gelatin.)

BY patient study and careful experimentation we have developed a treatment for this troublesome affection that has proven by clinical tests in the successful handling of hundreds of cases, and at the hands of various clinicians, to be as nearly specific as it is possible for a treatment to be—a treatment that at the same time cures quickly (6 to 12 days), safely (no strictures or other disagreeable sequela), and pleasantly (no pain or discomfort), and is easily used.

Most Physicians, and especially those using our remedies, have all the means at hand in regular stock, except our Drainage Bougies which make the treatment complete.

These Bougies are put up in boxes of 12, at a uniform price, to the Physician, of 60c. per box—$6.00 per dozen boxes, either kind, or assorted. It takes about three dozen No. 1 and one dozen No. 2 for an average case, the treatment of which rarely extends beyond the eighth day.

**A full box of Bougies (either No. 1 for acute or No. 2 for chronic cases) will be sent ONCE ONLY to any practicing physician, postpaid, on receipt of 25 Cents.**

### WHAT DO YOU SAY, DOCTOR,

to letting us send you a TRIAL OUTFIT, sufficient for two or three average acute cases? For example:

| | | | |
|---|---|---|---|
| 5 Boxes No. 1 Candle Bougies | Wholesale price, | | $3.00 |
| 1 Box No. 2 Candle Bougies | " | " | .60 |
| 1 Ounce of Ichthyol | " | " | .50 |
| 1,000 Calcium Sulphide 1-6 | " | " | .50 |
| 500 Triple Arsenates | " | " | .65 |
| 500 Waugh Laxative Granules | " | " | .30 |
| 2 Cans Saline Laxative | " | " | .70 |
| Total | " | " | $6.25 |

**This we will send you on receipt of $5.00,** and if the treatment does not prove satisfactory in your hands you may return the unused portion and we will refund your money.

DOCTOR, if you have a case that is bothering you try the treatment at our risk. If you haven't one just now, we suggest that you get ready for the one that's sure to come.

If you have any part of the above, and wish to do so, you may deduct the price following the article and remit the balance of five dollars for the balance of the goods.

Full outline of our method of treatment sent on request. As samples are useless, and the success of the treatment unquestionable, we advise the purchase of bougies in quantity as above, with "Your money back if not satisfied." Postpaid for cash with order.

**We are ready, suppose you do it now.**

☞ **Write the Most Convenient Point.** ☜

# GLYCO-THYMOLINE

INDICATED
IN TREATMENT OF

## Summer Complaints

ASEPTIC
ALKALINE
ALTERATIVE

Dr._____ Reports following case:

GASTRO-ENTERITIS, where there was constant vomiting. Child, twelve months old; gave one-half teaspoonful Glyco-Thymoline in hot water every hour until five doses were taken, also used Enema of Glyco-Thymoline, one tablespoonful in four ounces of water. This treatment gave prompt relief, and I believe saved the child's life.

Dr._____ Reports following case:

DYSENTERY: Patient, 16 months old, took to vomiting and running off at bowels six days before I was summoned. When I reached there, found the patient passing foul and bloody discharges, immediately put patient on Glyco-Thymoline and Liquid Bismuth, equal parts, teaspoonful every two hours; just after the second dose was given I could see a marked change. Patient improved fast, and in about three days had completely recovered.

Other similar cases treated with Glyco-Thymoline gave me equally good results.

SAMPLES ON APPLICATION

KRESS & OWEN COMPANY, 210 Fulton Street, New York

Lysol

# The Ideal Antiseptic

Especially adapted to gynaecological work because, in all solutions required for asepsis, it is

**Absolutely Safe and Non-Irritant.**

***We append a few recent expressions of opinion regarding LYSOL in gynaecology:***

**Stanley P. Warren,** *American Journal of Obstetrics*, January, 1902: "I sterilize my hands and arms, washing them first in hot water and green soap, and then in lysol solution one per cent. My reasons for adopting lysol as a germicide in obstetrics are its efficiency, its safety, its lubricity, and its cheapness. The literature of the Maine State Board of Health says: 'It is undoubtedly more efficient than carbolic acid; disinfection of the hands is assured by using a one-per-cent. solution without the previous use of soap; a one-fourth-per-cent. renders instruments sterile and does not attack the instruments. It is eight times less poisonous than carbolic acid and much less so than sublimate.'"

**Winslow Anderson,** *Professor of Gynæcology and Abdominal Surgery, College of Physicians and Surgeons, San Francisco*, describes part of his procedure in preparing the site of operation in the following words: "Twenty-four hours before a cœliotomy, the patient is given her second general antiseptic bath, the abdomen is scrubbed with green soap and hot water, and the parts shaved, then scrubbed with one per cent. lysol and hot water."

In an article on the "Diagnosis, Prevention and Treatment of Puerperal Infection," (*Journal of American Medical Association*, April 19th, 1902) **Dr. C. B. Reed** cites one of those typical instances where lysol is practically the only agent that can be employed resultfully and with safety. He says: "In case of abortion, where sepsis is already present, the uterus should be curetted at once and the cavity thoroughly washed out with a hot one-per-cent. lysol solution. Bichloride is to be avoided."

Among other prominent gynaecologists who have recently expressed a preference for lysol may be mentioned **Dr. Frederick Holme Wiggin,** Visiting Gynæcologist to the City Hospital, New York (*Medicine*, December, 1901, and *The Therapeutic Gazette*, April 15, 1902); **Dr. J. B. Killibrew** (*Medical News*, January 25, 1902); and **Dr. James Moran,** Instructor in Gynæcology in the New York School of Clinical Medicine (*N. Y. Medical Journal*, May 31, 1902).

# INFLAMMATION

"The succession of definite changes occurring in a living tissue when injured, provided the injury is not sufficient in degree to at once destroy the vitality of the part."

OR

"The succession of changes occuring in a living tissue from the action of pathogenic microbes or their ptomaines."

Take either view of the condition, it is the only indication for the use of

## Antiphlogistine

Turn to your text-book on surgery to-day and refresh your memory upon what constitutes "the succession of definite changes"; also note, if you please the condition of the circulation in the part affected; then remember

## Antiphlogistine

Is the most approved method of counteracting these very abnormal conditions whether they exist in deep-seated organs or superficial structures. If you believe in moist heat, venesection, cupping, hot stupes, blisters and other methods of counter-irritation, lay aside all prejudice and take up Antiphlogistine. It combines all the good features of the barber-surgeon methods just mentioned and produces definite results in a definite manner—no irritating, depressing, annoying or disagreeable after-effects, yet positively effective.

## Antiphlogistine

When applied warm and thick over the affected area, immediately energizes the adjacent tissues, stimulates the cutaneous reflexes, co-incidently causing contraction of the deep-seated and dilatation of the superficial blood-vessels. Extension of infection is at once prevented. The overworked heart is relieved by lessened blood-pressure and pain in the congested district is diminished. Normal conditions are soon restored.

ALWAYS PRESCRIBE A FULL PACKAGE

Small, Medium, Large or Hospital Size,

and thus insure obtaining Antiphlogistine in perfect condition.

LONDON. DENVER. NEW YORK.

# BUFFALO LITHIA WATER

## A Powerful Nerve Tonic. Its Action as a Tonic and Alterative Similar to That of the Hypophosphites of Lime and Soda.

**HUNTER McGUIRE, M.D., LL.D.,** *late President and Professor of Clinical Surgery, University College of Medicine, Richmond, Va., and Ex-President of the American Medical Association:* "BUFFALO LITHIA WATER, SPRING No. 2, has never failed me as a powerful nerve tonic when I have prescribed it as such. I sometimes think it must contain Hypophosphites of lime and soda. It acts as that compound does—as a tonic and alterative. This water as an Alkaline Diuretic is invaluable. In Uric Acid Gravel, and, indeed, in diseases generally dependent upon a Uric Acid Diathesis, it is a remedy of extraordinary potency. I have prescribed it in cases of Rheumatic Gout, which had resisted the ordinary remedies, with wonderfully good results. I have used it also in my own case, being a great sufferer from this malady, and have derived more benefit from it than from any other remedy, and I will add that I prescribe this water *ten times* where I prescribe any other *once*.

**Dr. GRAEME HAMMOND** *of New York* says: "In many cases of impotency, its restorative qualities have been of undoubted assistance. I have long regarded BUFFALO LITHIA WATER as the most valuable mineral water to use."

**Dr. CHAS. G. HILL,** *Professor of Nervous and Mental Diseases in Baltimore Medical College, etc.* writes: "BUFFALO LITHIA WATER is my favorite of all alkaline mineral waters, and I always order it when I am anxious to get decided results. In * * * many forms of nervous exhaustion, accompanying an excess of urates and phosphates, it is invaluable."

**Dr. GEORGE HALSTED BOYLAND, A.M., M.D.,** *of Paris, Doctor of Medicine of the Faculty of Paris, formerly Professor in the Baltimore Medical College. (From New York Medical Journal, August 26, 1887.)* "The writer, who has had a large experience in the treatment of diseases of the NERVOUS SYSTEM by these waters, extending over a period of four seasons as Resident Physician at the Buffalo Lithia Springs, is decidedly of the opinion that their chemico-physiological action is analogous to that of the hypophosphites. I now prescribe this water freely in all cases where loss of nerve force and want of tone are present, without further classification of the malady."

***ADDITIONAL MEDICAL TESTIMONY ON REQUEST.***

**Proprietor, BUFFALO LITHIA SPRINGS, VA.**

# BUFFALO LITHIA WATER

**In Uric Acid Diathesis, Gout, Rheumatism, Calculi, etc., Its Effects are Marked in Causing Disappearance of Albumen and Decidedly Beneficial in Certain Stages of Bright's Disease. It Disintegrates Uric Acid, Phosphatic and Oxalic Sediment.**

**STRONG TESTIMONY FROM THE UNIVERSITY OF VIRGINIA.**

"IT SHOULD BE RECOGNIZED AS AN ARTICLE OF MATERIA MEDICA."

**JAMES L. CABELL, M.D., A.M., LL.D.,** *formerly Professor of Physiology and Surgery in the Medical Department of the University of Virginia, and President of the National Board of Health,* says: "BUFFALO LITHIA WATER in Uric Acid Diathesis is a well-known therapeutic resource. It should be recognized by the profession as an article of Materia Medica."

"NOTHING TO COMPARE WITH IT IN PREVENTING URIC ACID DEPOSITS IN THE BODY."

**Dr. P. B. BARRINGER,** *Chairman of the Faculty and Professor of Physiology, University of Virginia, Charlottesville, Va.,* writes: "In more than twenty years' practice, I have used lithia as an anti-uric Acid agent many times, and have tried it in a great variety of forms, both in the natural waters and in tablets. As the results of this experience, I have no hesitation in stating that for the prompt results I have nothing to compare with BUFFALO LITHIA WATER in preventing Uric Acid deposits in the body."

"I KNOW OF NO REMEDY AT ALL COMPARABLE TO IT."

**Dr. WM. B. TOWLES,** late *Professor of Anatomy and Materia Medica, University of Virginia:* "In URIC ACID DIATHESIS, GOUT, RHEUMATISM, RHEUMATIC GOUT RENAL CALCULI and STONE IN THE BLADDER I know of no remedy at all comparable to BUFFALO LITHIA WATER, SPRING No. 2. Its effects are marked in causing a disappearance of Albumen from the urine, and I have witnessed decided beneficial results from its use in certain stages of BRIGHT'S DISEASE.

ITS MODE OF ACTION SUGGESTED

**Dr. J. W. MALLET,** *Professor of Chemistry, University of Virginia: Extract from report of analysis of Calculi discharged by patients under the action of* BUFFALO LITHIA WATER, SPRING No. 2: "It seems on the whole probable that the action of the water is primarily and mainly exerted upon the Uric Acid and the Urates, but when these constituents occur along with and as cementing matter to Phosphatic or Oxalic Calculus materials, the latter may be so detached and broken down as to disintegrate the Calculus as a whole in these cases, also thus admitting of urethral discharge."

ADDITIONAL MEDICAL TESTIMONY ON REQUEST. **Proprietor, BUFFALO LITHIA SPRINGS, VA.**

---

Dr. W. C. Glasgow, of St. Louis, in an article printed in the "Medical Record," says:

I believe that we have in CREOSOTE a remedy which defertilizes the lung tissue and renders it an unfavorable soil for the growth and development of micro-organisms. It is also an excellent expectorant. Combined with other measures to promote nutrition, it seems to me to be the best remedy which we have up to the present time to favor an arrest of many forms of tubercular disease.

# MISTURA CREOSOTE COMP.

**(KILLGORE'S)**

**Will meet all the requirements of the *creosote* treatment. It is made from the best *Beechwood Creosote*, combined with the tonic aromatics, and positively contains *no opiates or narcotics in any form.* It prevents fermentation and aids digestion and assimilation. Each teaspoonful contains two minims of *Beechwood Creosote.* Dose, one teaspoonful in one third of a glass of milk or water after meals. Samples sent to Physicians on request.**

## CHARLES KILLGORE

**MANUFACTURING CHEMIST. 82 and 84 Fulton St., NEW YORK.**

# CONCENTRATED—PROMPT—POWERFUL

## FRELIGH'S HEART DROPS
A TRUE CARDIAC TONIC

FORMULA: Cactus Grand., Cannabis, Convallaria, Kalmia, Pulsatilla.
DOSE: 3 to 5 drops, in water, three or four times a day.

In all cases where there is a weakened action of the heart, following an attack of the "Grippe," after Typhoid, in Chronic Diseases, these Drops will be found of marked value, acting promptly, and perfectly *safe* to use in every case where indicated. No reaction ever follows the use of them, and when the need of them has passed, they can be discontinued at once, no tapering off required.

## FRELIGH'S LIVER MEDICINE
A TRUE HEPATIC TONIC

FORMULA: Carduus Ben., Chelidonium Maj., Chionan. Vir., Helonias Di., Hydrastis Can., Leptan. Vir., Nux, Podolph. Pel.
DOSE: 3 to 10 drops, in glass of water, morning and night.

That rare thing, a true hepatic tonic, free from all cathartic or purgative action, it tones the liver up to a normal condition, where it will perform its normal functions without the lash or spur of drugs.

## FRELIGH'S TONIC
THE PHOSPHORIZED CEREBRO-SPINANT

FORMULA: Cinchona, Nux, Ignatia, Matricaria, Gentian, Phosphorus.
DOSE: 3 to 10 drops, in water, before each meal, with careful regularity.

As a Brain and Nerve tonic it has stood the test of 17 years, and is still unequalled for the treatment of Paralysis, Locomotor-Ataxia, Epilepsy, Neurasthenia, Senile and General Debility, Mental Failure, Debilitating Losses, Spinal Weakness, Nervous Dyspepsia, all troubles affecting the Brain, Nerve Centres and Spinal Cord, and as a safe and powerful Aphrodisiac.

**Each of the above is put up in only one style, without menstruum, at retail price of $1.00. None of them is ever sold in bulk or in Tablet form. Anything, under any of the above names, offered in bulk or in Tablet form, is prima facie evidence of fraud.**

**Samples, each sufficient for ten days' trial, of any or all of the above, mailed to any physician upon request. As we furnish no samples through the trade, either wholesale or retail, all requests for samples must be made direct to**

PAN-PEPTIC
TABLETS
25¢ - 50¢ - 100¢

**PANOPEPTON** contains 20% of solids: protein 6%, carbohydrates 13%, mineral constituents 1% — these determined by the usual methods of food analysis: the solids by drying in a water bath oven at 100° C.; the proteins by the modified Kjeldahl method—N x 6.25.

**Panopepton** is obtained from lean beef and whole wheat by the action of the animal enzymes, and under conditions approximating to those of bodily digestion. The process is so conducted as to obtain the whole group of natural derivatives of digestion—both protein and carbohydrate. Panopepton contains the entire soluble and digestible constituents of each food in their natural association and united in definite proportions on the basis of actual assay. The base is sound Spanish sherry wine, each cask of which is submitted to expert examination and assay. No chemical preservative is used. Genuine Spanish sherry wine presents the best vehicle for the preservation of these peptonised foods in a form of the widest range of utility.

**Panopepton** is a sterilised, standardised product of definite design and uniform composition and quality. Each bottle bears upon its label a recorded assay number.

**Panopepton** presents the highest content of food constituents, highest content of protein and highest and best considered nutritive balance—ratio of protein to carbohydrate; and is superior in all respects to other preparations containing peptonised food of any kind in an alcoholic menstruum. It is absolutely free from cane sugar; yet it compares favorably in agreeability with preparations of even the smallest actual food content.

Clinical experience with Panopepton has confirmed the reasonable anticipation that a complete scientifically standardised food in a freely diffusible form must possess in the highest degree the nourishing and restorative properties of the native foods, and at the same time afford the immense advantage of conserving bodily energy and avoiding the ill effects of mal-digestion.

On all grounds, chemical, physiological and clinical, Panopepton is to be considered a food by itself, presenting great superiority to other foods, and having qualities peculiar to itself for the support and nutrition of the sick and as a resource against exhaustion. In surgical cases it is particularly serviceable.

# THE FAMILY LAXATIVE.

THE ideal safe family laxative, known as SYRUP OF FIGS, is a product of the California Fig Syrup Co., and derives its laxative principles from senna, made pleasant to the taste and more acceptable to the stomach by being combined with pleasant aromatic syrups and the juice of figs. It is recommended by many of the most eminent physicians, and used by millions of families with entire satisfaction. It has gained its great reputation with the medical profession by reason of the acknowledged skill and care exercised by the California Fig Syrup Co. in securing the laxative principles of the senna by an original method of its own, and presenting them in the best and most convenient form. The California Fig Syrup Co. has special facilities for commanding the choicest qualities of Alexandria senna, and its chemists devote their entire attention to the manufacture of the one product. The name—SYRUP OF FIGS—means to the medical profession "the family laxative, manufactured by the California Fig Syrup Co.," and the name of the Company is a guarantee of the excellence of its product. Informed of the above facts, the careful physician will know how to prevent the dispensing of worthless imitations when he recommends or prescribes the original and genuine SYRUP OF FIGS. It is well known to physicians that SYRUP OF FIGS is a *simple, safe* and *reliable* laxative, which does not irritate or debilitate the organs on which it acts, and, being pleasant to the taste, it is especially adapted to ladies and children, although generally applicable in all cases. Special investigation of the profession invited.

## SYRUP OF FIGS

Is never sold in bulk. It retails at fifty cents per bottle, and the name—SYRUP OF FIGS—as well as the name of the California Fig Syrup Co., is printed on the wrappers and labels of every bottle.

## CALIFORNIA FIG SYRUP CO.,

LOUISVILLE, KY. SAN FRANCISCO, CAL. NEW YORK, N. Y.

# SUMMER COMPLAINT

A well-known physician, after twenty-five years' practice, once said to us, "If I were limited to half a dozen remedies and could make my own choice, **Alkaline Elixir** (or as it is now called, **Alkarhein**) would be one of the first that I would name. It is not only the best of all remedies for Summer Complaint, but is of value in practically every form of intestinal disturbance—certainly in all those in which there is fermentation of the contents of the alimentary canal."

**Alkarhein** is composed of Rhubarb, Golden Seal, Pottassium Bicarbonate, Sodium Bicarbonate, Cinnamon, Peppermint, Pancreatin and Brandy, and the indications for its use are above outlined.

Dr. Wm. B. Mann, 1570 Asbury Ave., Evanston, Ill., writes:

"Your Alkaline Elixir (**Alkarhein**) is an ideal pharmacal preparation, and is my favorite remedy for Summer Complaint in infants and older children as well. I believe it, at least, equal, if not superior to any preparation for such use. Being a graduate in pharmacy as well as in medicine enables me to judge its merits."

In **Gastritis, Enteritis,** and **Gastro-Enteritis Alkarhein** may, with advantage, be alternated with Solution Bismuth and Hydrastia, as in these cases the mechanical sedative, antiseptic and astringent action of this remedy exerts a favorable effect on the inflamed mucosa. **Alkarhein** and **Solution Bismuth** and **Hydrastia** are prepared only by

# Text-Book of Nervous Diseases.

**By CHARLES L. DANA, A.M., M.D.,**

**Professor of Nervous and Mental Diseases, in Bellevue Hospital Medical College; Visiting Physician to Bellevue Hospital; Neurologist to the Montefiore Home; Ex-President of the American Neurological Association, etc.**

THE fourth edition of Dr. Dana's book is slightly enlarged and practically rewritten. The part on Peripheral Neuroses is entirely rearranged; new chapters have been added on Encephalitis, Multiple Sclerosis, Meningitis, and Traumatic Neuroses. The anatomical chapters have all been revised and rewritten, and the anatomy and pathology of the work have been brought into relation with modern views as to the neuronic architecture of the nervous system. The Therapeutical part has been extended by additions to the appendix, giving technical details of the various accepted therapeutic measures of modern neurology.

Many new illustrations have been added. Withal, however, the book has been but slightly enlarged, and its general character, which has met with such universal approval in the preceding editions, has not been changed. It presents modern neurology in a concise yet clear and accessible form.

**One volume, of 640 pages octavo, illustrated by 246 engravings in the text, and three full-page plates. Muslin, $3.50 *net*.**

**WILLIAM WOOD AND COMPANY, Publishers, - New York.**

# CANDULETS

## FOR GONORRHEA

**MITCHELL'S URETHRAL CANDULETS** (**LITTLE BOUGIES**) are intended to supply to the general practitioner an effective and practical method for the treatment of Gonorrhea and Gleet which can be readily dispensed, when necessary, to office patients, without the necessity of written prescriptions. They are put up in such style as to be compact, convenient and inexpensive, a complete treatment for several days being contained in each package.

The Candulets are long urethral suppositories, four inches in length and three-sixteenth inch in diameter, corresponding in size to a No. 14 Catheter, French Scale. They are made of a soluble compound of Gelatin and Boroglyceride, to which suitable medicinal remedies have been added. They will not melt or become sticky even if freely handled; they are flexible and elastic, and can be bent double or tied in a knot without breaking; they will not become hard or insoluble with age; while the glycerin vehicle used assists greatly in the absorption of the medicating ingredients. When introduced in the urethra the Candulet gradually dissolves in the mucous secretions, coating the membranes with a bland non-irritating medium which is both demulcent, soothing and antiseptic. The medicating remedies being either dissolved or thoroughly incorporated with the glyco-gelatin basis, exert an immediate local effect as soon as the Candulet begins to dissolve, and its therapeutic impression continues until it is entirely melted, thus insuring a prolonged, thorough, direct and most effective action, lasting for hours.

## LIST OF FORMULAS

**No. 410.—PROTARGOL-ICHTHYOL.**

Protargol, Ichthyol, Creosote, Hydrastis, Extract Belladonna, Menthol and Thymol.

**No. 411.—PROTARGOL-ZINC.**

Protargol, Zinc Iodid, Hydrastis, Extract Hyoscyamus, Menthol and Thymol.

**No. 412.—PROTARGOL-ANTIPYRIN.**

Protargol, Antipyrin, Carbolic Acid, Zinc Sulphate, Hydrastis, Extract Belladonna, Cocaine.

**No. 413.—ZINC-ANTIPYRIN.**

Zinc Sulphate, Antipyrin, Creosote, Hydrastis, Extract Hyoscyamus, Boric Acid, Etc.

**No. 414.—ZINC-HYDRASTIS.**

Zinc Iodid, Zinc Chlorid, Boric Acid, Carbolic Acid, Hydrastis.

**No. 415.—ZINC-BELLADONNA.**

Zinc Sulphate, Carbolic Acid, Hydrastis, Extract Belladonna.

**MITCHELL'S CANDULETS** are put up in neat wood boxes, without descriptive labels, containing sufficient to treat an ordinary case of gonorrhea or gleet for several days. Each box contains six Candulets with full directions for use. This quantity will be found as a rule sufficient to keep the patient under proper treatment during the interval between his visits to the physician. A full box or unbroken package should, therefore, always be supplied, and the patient charged, *at least*, the *full retail price*, in addition to the regular fee.

**PRICE, PER BOX, Retail, 50 Cents. To Physicians, 40 Cents.**

**(SPECIAL RATES TO PHYSICIANS PURCHASING IN QUANTITIES.)**

**SAMPLES.**—Owing to the extremely low price at which the Candulets are sold, DR. MITCHELL does not supply free samples. He will, however, *just once*, mail to any physician desirous of testing the Candulets, **ONE** full, regular size box (either formula) for **TEN CENTS.** Enclose professional card or letter heading and mention the MEDICAL RECORD.

**CHARLES L. MITCHELL, M.D., 1016-18 Cherry St., Philadelphia.**

# Euquinine

## Perfected Quinine

These two points about Euquinine should interest every physician:

1. Euquinine contains more of the quinine radical, weight for weight, than sulphate of quinine does.

2. It is *tasteless*. Children take it without compulsion and adults without repugnance. "Finest preparation of quinine I have every used," is the statement of a physician after thoroughly testing Euquinine.

**Saloquinine.** Antineuralgic. "In supraorbital neuralgia if the drug was given 4 hours before the expected attack it prevented its occurrence."

**Saloquinine Salicylate** "It is a welcome acquisition for the treatment of complications of acute rheumatism."

Clinical Reports to Physicians.

**MERCK & CO.** UNIVERSITY PLACE, NEW YORK

SIXTH EDITION

# THE SURGERY OF THE RECTUM

By CHARLES B. KELSEY, A.M., M.D.,

Late Professor of Pelvic and Abdominal Surgery at the New York Post-Graduate Hospital, and Professor of Rectal Surgery at the University of Vermont.

SIXTH EDITION

**Octavo, 411 pages, Illustrated by 215 engravings; Muslin, $3.00 net.**

IN the sixth edition of this well-known work the author presents the experience of twenty-five years practice of this important specialty. Some surgery of other pelvic and abdominal organs is necessarily included, as operations upon the Rectum frequently involve them. The book has been entirely re-written, and represents the latest developments of rectal surgery and treatment. While the book contains all recent scientific advances, as well as the writer's personal experience, the aim has been to leave out all matter not of practical value, to condense as far as possible, and to produce a concise work adapted to the wants of those who desire to treat intelligently all Rectal Affections, no matter what their complications may be.

SYNOPSIS OF CHAPTERS

Chapter I. Examination and Diagnosis.
" II. General Rules regarding Operations.
" III. Congenital Malformations.
" IV. Inflammation of the Rectum.
" V. Ulceration of the Rectum.
" VI. Stricture of the Rectum.
" VII. Rectal and Peri-Rectal Abscess.
" VIII. Fistula.
Chapter IX. Hemorrhoids.
" X. Prolapse of the Rectum.
" XI. Intussusception.
" XII. The Formation and Closure of Artificial Anus.
" XIII. Intestinal Resection of Anastomosis.
" XIV. Tumors of the Rectum and Anus.
" XV. Cancer.
Chapter XVI. Constipation and Fecal Impactions.
" XVII. Wounds of the Rectum.
" XVIII. Foreign Bodies.
" XIX. Affections of the Genito-Urinary Organs.
" XX. Affections of the Male Genital Organs.

**Sent, post-paid, to any address on receipt of the price.**

**WILLIAM WOOD & COMPANY, Publishers, 51 FIFTH AVENUE, NEW YORK**

# ERGOAPIOL (SMITH)

## THERAPEUTIC QUALITIES

THE absolute absence of all OPIATES, NARCOTICS, and ANALGESICS, thus offering, instead of false roundabout and mere transitory relief, a true and scientific treatment for AMENORRHEA, DYSMENORRHEA, and other IRREGULAR MENSTRUATION.

In these conditions and the most obstinate cases of SUPPRESSED and RETARDED MENSTRUATION, Ergoapiol (Smith) (though devoid of the above unpleasant features, which are so often followed by a sad sequela) possesses a remarkable power to obviate pain and to bring about a healthy activity of the menstrual functions through its direct tonic and stimulating effect upon the Uterus and its appendages.

## CAUTION.

To obviate Substitution or other possible error in compounding, it is advisable always, besides specifying ("Smith") when prescribing Ergoapiol (Smith), to order in Original Packages only, as in facsimile prescription appended.

These packages contain twenty capsules each, and are so constructed that all printed matter pertaining thereto can be readily removed.

℞

# The Theory and Practice of Infant Feeding

## WITH NOTES ON DEVELOPMENT

**By HENRY DWIGHT CHAPIN, A.M., M.D.**

"THIS work places the subject of infant feeding on a broader, more scientific basis than any of its predecessors have done."—*Buffalo Medical Journal.*

The Medical press of the United States and England have recognized Dr. Chapin's general treatment of the subject as new and original. While breast feeding is preferred and the best methods for its conservation are given, it is recognized that many infants must be brought up on cow's milk. The production and handling of milk, from the cow and dairy farm to the consumer, is plainly but exhaustively treated, so that a physician or health officer in the most isolated neighborhood can inaugurate a clean and wholesome milk supply. Easy and accurate methods of modifying the milk, so as to render it suitable for different ages, are plainly set forth. The diet suitable in health and the various digestive disorders, such as difficult digestion, **COLIC, CONSTIPATION,** and **DIARRHŒA** are specially treated. Forced feeding, rectal feeding and an easily recognizable classification of infant stools are also given. A separate chapter is devoted to **SUMMER DIARRHŒA** and the **EFFECT OF HOT WEATHER** upon the food and vitality of infants. Meats, eggs, broths, cereals and the principles of dietetics in general, with preservatives in common use, are likewise considered. The final part of the work is devoted to growth and development, with normal measurements in health. The book is of the greatest value to the general practitioner, health officer, milk dealer and sanitarian.

**Octavo, 328 pages, including a full index; illustrated by numerous cuts, charts and half-tone engravings. Muslin, $2.25 *net*.**

WARNING!

It has recently come to our attention that some unscrupulous persons have been putting on the market a set of hard rubber spray tubes identical in outside appearance to our well-known No. 65 Atomizer. The tips of these inferior counterfeits have not the platinum lining which is one feature of the Davidson Sprays, and the interior mechanism is cheaply and inefficiently made. The obvious intention is to deceive the purchaser. This bunco proceeding can be defeated if the buyer is careful to note that the name Davidson Rubber Co. is stamped on each hard rubber tube.

DAVIDSON RUBBER CO.,
BOSTON, MASS.

Wounds in War.

THE MECHANISM OF THEIR PRODUCTION AND THEIR TREATMENT.

By Surgeon-Colonel W. F. Stevenson,
Professor of Military Surgery, Army Medical School, Netley, England.

The author remarks in the Preface: "As the improvements which have taken place in modern surgery have necessitated changes in the methods of treatment of gunshot wounds, as of all others, so also the very conditions themselves of these injuries have changed. The projectiles which, for the most part, cause them, and the small arms now in the hands of soldiers, are quite different from those formerly in use, and produce injuries, both of soft parts and of bone, quite unlike those seen in even the later campaigns.

"To indicate the lines on which the modern treatment of wounds in war should be carried out in special injuries of particular parts of the body, and to point out what methods are calculated to bring about the best results in the preservation of lives and limbs in individual cases, have been the objects aimed at in the following pages."

# Supplement to the Twentieth Century Practice

**An International Encyclopedia of Modern Medical Science by Leading Authorities of Europe and America**

Edited by THOMAS L. STEDMAN, M.D., NEW YORK CITY

WITH the beginning of the twentieth century the tireless activity in scientific research that characterized the closing years of the nineteenth has in nowise abated. New truths have been discovered, half recognized facts have been brought out into the clear light, and some cherished theories have been weakened or overthrown. For these reasons it has been thought that a supplementary volume to the TWENTIETH CENTURY PRACTICE would be welcomed by those who possess that work. Most of what is contained in this great encyclopedia of medicine is, indeed, as fresh to-day as when it was written, but the rapid advance of medical knowledge has made necessary a revision of a few of the articles and an amplification of others. In the case of yellow fever, for example, the work of the medical officers of the United States Army in Havana has so widened our knowledge of the etiology of the disease, and as a result shown us the means of its prevention, that an entirely new treatise has been called for. This has been prepared by the man at whose incentive the work was undertaken, Ex-Surgeon General Sternberg. Experience in the Philippines has demonstrated beyond question the fact that what is called dysentery is not a morbid entity, but embraces at least two diseases—a bacillary and an amœbic dysentery. Dr. Shiga of Japan, the discoverer of the bacillus that bears his name, has accordingly contributed an article treating of bacillary dysentery. The discovery of Röntgen was almost coincident with the beginning of the TWENTIETH CENTURY PRACTICE, and the medical applications of the *x*-rays are now so definitely established that the time has come for an article devoted to the subject, and such a one has been written by Dr. Carl Beck, of New York, one of the pioneers in this new science. The blood has been an especial object of study in recent years, and diagnostic significance of the variations in number and form of its cell constituents and the chemical changes incident to antitoxin formation and the production of immunity being the two main lines along which researches have been instituted. These two subjects have been thoroughly modernized by active workers in their respective fields. Another center of interest at the present time is the pathogenesis of cancer. An article reviewing the work thus far accomplished by the searchers after a specific germ of malignant growths has been contributed by Mr. Roger Williams, and Dr. Coley has supplemented his previous article by a presentation of what has been accomplished in the way of the *x*-ray treatment of cancerous growths. Between thirty and forty other brief articles have been written by the authors of the original treatises, revising or adding to their previous contributions. In short, the aim of the publishers in issuing this volume is, by supplying deficiencies and correcting what further investigation has shown to be erroneous, to place the original work again abreast of the times and to validate anew the title of the TWENTIETH CENTURY PRACTICE OF MEDICINE.

**Write for special terms on which the Encyclopedia will be sold.**

The SUPPLEMENT consists of one royal octavo volume, of 856 pages, illustrated, uniform with the volumes of the set, and is sold by subscription only at $5.00 in cloth; $6.00 in leather; and $7.50 in half morocco binding.

THE OLD HOSPITAL
AND OTHER PAPERS.
By D. B. ST. JOHN ROOSA, M.D., LL.D.
Being the second revised and enlarged edition of
"A DOCTOR'S SUGGESTIONS."

In this edition, besides the change in the title, there have been added three new essays, making eleven in all. As the author states in his preface, "the central idea of the papers is an attempt to define and adjust the relations of the medical profession to the community which it serves." The book is, therefore, of interest to laymen as well as to physicians.

As a specimen of the book-maker's art this volume is seldom surpassed in excellence. It is printed on heavy laid paper, natural color, with a wide margin; gilded on top, and uncut. The binding is dark olive cloth with gold lettering on the back; the whole making an exceedingly attractive and artistic book. Price, $3.00 *net*.

WILLIAM WOOD AND COMPANY, Publishers,
New York.

A SUPERB WORK.

ATLAS OF HUMAN HISTOLOGY

By DR. ARNOLD BRASS, Göttingen
AUTHORIZED TRANSLATION FROM THE GERMAN, WITH ADDITIONS
By R. A. YOUNG, M.D., B.Sc., Lond.
*Lecturer on Physiology at the Middlesex Hospital Medical School, London.*

THE author informs us in his preface that "the special features of the present Atlas are the nature and method of the illustrations. There is no lack of good text books of normal Histology for the practitioner, but there is a need for a good illustrated work, the plates of which shall present as exactly as possible the appearance of the actual tissues as they are seen by the aid of the microscope."

Almost every illustration is from a fresh specimen, the author having had unusual facilities in this respect. The degree of magnification is, throughout the work, that which is necessary to see the structure distinctly.

THE PLATES are devoted to the various portions of the body as follows. Cellular Structures—3 plates: The Skin—6 plates: Sense Organs—7 plates: The Nervous System—14 plates: Muscle—2 plates: Connective Tissues—4 plates: Organs of Digestion—12 plates: Organs of Respiration—2 plates: The Vascular System—7 plates: Urinary Organs—3 plates: Generative Organs—5 plates: in all 65 plates, containing 300 separate figures.

The plates are exquisitely printed, in many tints and colors, from stone and copper. The explanation faces the plate in every case, and the whole is made readily accessible by a very complete index.

BOUND IN EXTRA BUCKRAM, IN SLIDE WITH COVER, $20.00 NET

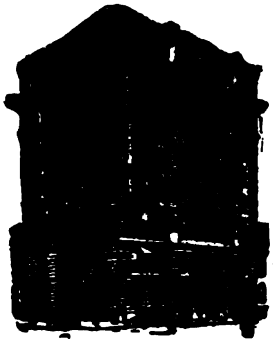
WILLIAM WOOD AND COMPANY, NEW YORK

# MEDICAL COLLEGES.

SESSION 1902-1903.

## The Long Island College Hospital

**Hoagland Laboratory and Polhemus Memorial Clinic.**



Next Regular Session begins Oct. 1, 1902.
Next Summer Course begins May 16, 1903.

UNEXCELLED CLINICAL FACILITIES. The teaching staff is represented in nearly all the hospitals on the east side of New York Harbor, and clinics held in these institutions are open to the students of this College. In the College Hospital and Dispensary 20,000 patients were treated in 1901. Practical clinical courses given in all special branches. Unexcelled laboratory facilities in Microscopy, Bacteriology, Chemistry, Pharmacy, Physiology, and Anatomy. Out-patient service in Obstetrics a part of regular curriculum. Send for announcement to

JOSEPH H. RAYMOND, M.D.,
Secretary of Faculty,
Long Island College Hospital, - New York City.

## UNIVERSITY OF PENNSYLVANIA.

DEPARTMENT OF MEDICINE. FOUNDED IN 1765.

The curriculum requires attendance at four annual sessions of eight and a half months each.

**Facilities for Instructions in Laboratory Branches:** The Chemical Laboratory, the Laboratory of Hygiene, Medical Hall, The Wistar Institute of Anatomy.

**The Laboratory of Pathology, Physiology and Pharmacodynamics,** now in course of erection at a cost of $600,000, to be formally opened during the next session, offers unsurpassed facilities for instruction in the fundamental branches.

**Facilities for Instructions in Clinical Branches,** situated on the University Campus and on the grounds adjoining, are: The Hospital of the University of Pennsylvania (capacity 300 beds); the Maternity Pavilion and Amphitheatre, property of the University; and the Philadelphia Hospital (capacity 1,000 beds). Clinical instruction is given by the teaching staff in other Hospitals, so that the clinical material at the disposal of the staff is drawn from hospitals with a total capacity of 1,785 beds.

**Courses to Graduates.** A comprehensive post-graduate course is given each year in all the laboratory and clinical branches, covering a period of eight weeks.

**Facilities for Research Work** are amply provided for in all the Laboratories of the Department, including the William Pepper Clinical Laboratory, instituted exclusively for graduate research work.

For further information concerning the Courses, or for Catalogue, address

DR. CHARLES H. FRAZIER, Acting Dean,
UNIVERSITY OF PENNSYLVANIA, - - - PHILADELPHIA, PENNA.

## Albany Medical College,

**Medical Department of Union University—1903-1904.**

ANDREW V. V. RAYMOND, D.D., LL.D.
Chancellor of the University.

ALBERT VANDER VEER, M.D., PH.D.,
Dean and Professor of Surgery.

JOHN M. BIGELOW, M.D., PH.D.,
Emeritus Professor Materia Medica and Therapeutics and Diseases of Throat and Nose.

SAMUEL B. WARD, M.D., PH.D.,
Professor of Theory and Practice of Medicine and Hygiene.

JAMES P. BOYD, M.D.,
Professor of Obstetrics, Gynecology, and Diseases of Children.

WILLIS G. TUCKER, M.D., PH.D.,
Registrar and Professor of Chemistry and Toxicology.

WILLIAM HAILES, M.D.,
Anthony Professor of Pathological Anatomy, Histology, and Fractures and Dislocations.

CYRUS S. MERRILL, M.D.,
Professor of Ophthalmology and Otology.

FREDERIC C. CURTIS, M.D.,
Professor of Dermatology.

HENRY HUN, M.D.,
Professor of Diseases of the Nervous System.

SAMUEL R. MORROW, M.D.,
Professor of Practice of Surgery and of Orthopedic Surgery.

HERMON C. GORDINIER, M.D.,
Professor of Physiology.

HOWARD VAN RENSSELAER, M.D.,
Professor of Materia Medica and Therapeutics.

JOSEPH D. CRAIG, M.D.,
Professor of Anatomy and Curator of Museum.

WILLIS G. MACDONALD, M.D.,
Professor of Abdominal and Clinical Surgery.

GEORGE BLUMER, M.D.,
Professor of Pathology and Bacteriology.

With the assistance of a corps of Lecturers, Instructors and Clinical Assistants.

**FEES.**—Matriculation, $5.00; Lectures, $100.; Four-Year Lecture Ticket $300; Dissection (Material Fee) and Laboratory Courses (see catalogue). Graduation Fee, $25.00.

## POST-GRADUATE SCHOOL OF THE WEST

Open throughout the entire year. Largest Clinics and finest Hospital facilities in the city. Work so arranged that practitioners can enter at any time with equal advantage to themselves. SUMMER term begins June 1st.

For schedule, announcement and full particulars, address M. L. HARRIS, M.D., Sec'y, 174-176 E. Chicago Ave., Chicago, Ill.

**Sixth Revised and Enlarged Edition.**

# HANDBOOK OF PATHOLOGICAL ANATOMY AND HISTOLOGY,

**With an Introductory Section on Post-Mortem Examinations and the Methods of Preserving and Examining Diseased Tissues.**

**By FRANCIS DELAFIELD, M.D., LL.D.,**

Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, New York,

AND

**T. MITCHELL PRUDDEN, M.D.,**

Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York.

This is without question the most exquisitely illustrated and the best printed medical text-book ever published. It is superbly illustrated by line and half-tone engravings of superlative excellence, printed in colors and tints, as well as in black, and by full-page plates in black and colors. The work is printed from new type, on plate paper.

One volume, of 839 pages, royal 8vo, illustrated by 453 engravings in black and numerous colors, and by 13 full-page inset plates in colors and in black. Extra muslin, **$5.00,** *net.* Leather, **$5.75,** *net.*

### PRESS OPINIONS.

"We are glad to welcome this sixth edition of a book that has long held its place among the best works of its kind in the English language. As an example of a text-book for students it leaves nothing to be desired."
*New York Medical Journal.*

"This edition is in reality a new book." *Medical News.*

"There is little doubt that the course of time will show this to have been the most important medical publication of the present year." *Medical Record.*

"Too much cannot be said in praise of this book—it is all that can be desired; has long been a standard, and will remain so."
*Louisville Journal of Medicine and Surgery.*

"Commendatory remarks are scarcely necessary to convince those acquainted with former editions that this, the sixth edition, holds the highest place among standard works on pathology."
*Kansas City Medical Index-Lancet.*

Part III. Certain Points Connected with the Treatment of Gout.
Part IV. The Treatment of Gout and of Gouty Conditions.

**The subject of diet has been carefully dealt with, and a classification of the various mineral waters is given according to their therapeutic value in the treatment of the various forms of gout.**

**WILLIAM WOOD AND COMPANY, Publishers, New York.**

# TREATISE ON ORTHOPEDIC SURGERY

**By EDWARD H. BRADFORD, M.D.,**
Surgeon to the Children's Hospital and to the Samaritan Hospital; Assistant Professor of Orthopedic Surgery, Harvard Medical School,
AND
**ROBERT W. LOVETT, M.D.,**
Assistant Surgeon to the Children's Hospital; Surgeon to the Infants' Hospital.

**SECOND REVISED AND ENLARGED EDITION. Illustrated by Six Hundred and Twenty-one Engravings.**

THE advance in Orthopedic Surgery in the last nine years has been so rapid that a revised edition of this work has necessitated very largely the rewriting of the entire book. But few changes in its scope or classification have been made.

Orthopedic Surgery, if properly defined, should include the prevention as well as the cure of deformity. For this reason the authors of this work have considered at some length the diseases of the joints, inasmuch as they are among the most common sources of deformity and disability. They have not confined themselves too closely to the definition of the term Orthopedic Surgery. Besides the consideration of joint disease and Pott's disease, there have been added brief descriptions of some disabling and deforming nervous affections, which are only discussed in their practical surgical aspect.

**One volume, octavo, 661 pages, illustrated with 621 engravings in line and half-tone, mostly new and original. Cloth, $4.50 net.**

**WILLIAM WOOD AND COMPANY, PUBLISHERS, NEW YORK.**

## PRIVATE HOSPITALS, SANITARIUMS, AND RETREATS.

# ALMA SPRINGS SANITARIUM, ALMA, MICHIGAN.

A magnificently equipped Sanitarium for the care and treatment of all chronic diseases, except insanity, tuberculosis and epilepsy. We have no "Fads," save those of Scientific Diagnosis and Treatment, and the conscientious personal care of the Medical Staff.

We are located in the most healthful and delightful section of Michigan. Beautiful grounds, plenty of indoor and outdoor amusements, a well equipped gymnasium, and an "up-to-date" bath department.

In fact, our Institution is a Hygienic Health Home where people are taught how to acquire health and keep it.

Our Mineral Waters, ALMA-BROMO and ALMARIAN, are in many respects the most remarkable waters in America. ALMARIAN water is unquestionably the best kidney and bladder water in the United States.

**Write for illustrated book giving full particulars.**

# Pathology and Treatment of Diseases of the Skin,

## FOR PRACTITIONERS AND STUDENTS.

**By DR. MORIZ KAPOSI,**

Professor of Dermatology and Syphilis, and Chief of the Clinic and Division for Skin Diseases in the Vienna University.

TRANSLATION OF THE LATEST GERMAN EDITION.

No excuse need be offered for an addition to the already long list of treatises on Dermatology in English, when one considers that wherever this branch of medicine is practised or taught, Kaposi's labors in the field and the diseases which bear his name are under constant discussion.

This book has already reached its fourth edition in the German, and is the standard text-book in the Austrian and German Universities a practical guarantee of its usefulness. The third edition has been translated into French, and is the standard text-book throughout France It is therefore not too much to expect that this American translation of the fourth and latest edition will meet with the degree of favor here that has been accorded the work in Europe.

The book is complete in one large octavo volume of 684 pages, illustrated by 84 engravings and one plate in colors, and is furnished with an unusually complete index. Bound in extra muslin at $4.00 *net* per copy, and in leather at $4.75 *net* per copy.

Sent to any address on receipt of the price. Descriptive circular sent on application.

**WILLIAM WOOD AND COMPANY, Publishers, New York.**

# ATLAS OF VENEREAL AND SKIN DISEASES.

SECOND EDITION
With additional new plates and half-tone engravings.

TEXT ENTIRELY REWRITTEN BY
JAMES C. JOHNSTON, A.B., M.D.,
Physician for Class of Skin and Genito-Urinary Diseases, Presbyterian Hospital; Dermatologist to Lying-in Hospital; Formerly Instructor in Dermatology, New York Polyclinic and Post-Graduate Medical School.

WITH THE ADDITION OF CHAPTERS ON ACUTE AND CHRONIC GONORRHEA BY
GEORGE KNOWLES SWINBURNE, M.D.,
Instructor in Genito-Urinary Surgery, Cornell University Medical College; Surgeon to Good Samaritan Dispensary.

*Among the distinguished gentlemen who have contributed selections from their collections of original illustrations may be mentioned: Kaposi, Neumann, Hutchinson, Fournier, Hardy, Ricord, Vidal, Leloir, Morrow, Keyes, Hyde, Piffard, Johnston, Hebra, Murchison, Priest, Allen, Cazenave, Montmija, Unna, Robinson, Araujo, Ouchterlony, and others.*

SINCE the work originally appeared, rapid and, it is believed, permanent advance has been made, in both venereology and dermatology; great changes in therapeutics and important developments as the result of skilful investigation necessitating such extensive changes that the editor of this revision deemed it best to write **an entirely new text,** thereby bringing the work up to date in every respect.

Dr. George K. Swinburne has contributed two new chapters on Acute and Chronic Gonorrhea, a subject which was not considered in the earlier form of the work, and which the distinguished author of that part is especially fitted, by great experience, to handle with exceptional ability.

Every physician will realize the importance and usefulness of pictorial representations of diseases of the skin as an aid to their ready recognition and differential diagnosis, and especially so to the vast majority of the profession, who are practically excluded from opportunities for clinical study, such as can be found only in the larger cities.

The examples selected for illustrations are not unusual or extraordinary conditions, so much as characteristic and **typical examples of the diseases which commonly occur.** The text includes the essential facts relating to the symptoms, diagnosis, and treatment, special attention being given to the latter. **The plates** are believed to be superior to anything of the kind heretofore produced, the coloring, which is one of the most essential features, being far superior to effects produced by any other process.

Altogether, considering the reputation of the authors of the plates, the ability of the editor, the artistic execution of the plates, the large size of the page, etc., etc., this ATLAS OF VENEREAL AND SKIN DISEASES is the most superb work in medical literature ever published in the English language.

A magnificent thick imperial folio volume (16½ x 12½ inches), which includes 240 pages of text, containing numerous half-tone engravings and **seventy-seven superb colored plates,** with several hundred figures, reproduced in the highest form of chromo-lithography. The work is sumptuously bound in half morocco. Price **$25.00.** Further particulars, including advantageous terms to purchasers on credit, will be supplied upon application.

**WILLIAM WOOD & COMPANY, Medical Publishers, 51, Fifth Ave., New York.**
